EDUARD REGEL.

AN

ILLUSTRATED WEEKLY JOURNAL

OF

HORTICULTURE IN ALL ITS BRANCHES.

FOUNDED BY

W. Robinson, F.L.S., Author of "Alpine Flowers," etc.

"You see, sweet maid, we marry
A gentle scion to the wildest stock
And make conceive a bark of baser kind
By bud of nobler race: This is an art
Which does mend nature—change it rather,
'The art itself is nature.'—*Shakespeare.*

VOL. XVI.—CHRISTMAS, 1879.

LONDON:

OFFICE: 37, SOUTHAMPTON STREET, COVENT GARDEN, W.C.

TO

M. EDUARD REGEL,

Director of the Botanic Gardens at St. Petersburg,

THIS SIXTEENTH VOLUME OF "THE GARDEN" IS DEDICATED

IN RECOGNITION OF HIS LABOURS IN THE INTRODUCTION OF HARDY PLANTS

TO THE GARDENS OF EUROPE.

v. 16

INDEX TO VOLUME XVI.

A.

Abelia rupestris, 275
 Abies and Picea, 543
 Abies Menziesi, 544
 Abrotina fragrans, 235
 Abrotina without water, 404
 Acacia Riceana, 148; and its treatment, 248; retinoides, 572
 Acauthuses in November, 446; in the wild garden, 325
 Acer Ginnala, 542; polymorphum, 568
 Achilleas, large white, 166
 Achimenes and their culture, 43
 Acorns, scarcity of, 335
 Acronycta psi, 426
 Actaea spicata, 112
 Adiantum Bausei, 258; cuneatum dissectum, 358; mundulum, 358; Farleyense, 548
 Agapanthus Mooreanus, 207; umbellat is, 447; albus, 207
 Agave americana, 480; a large, 208; marmorata, 272
 Agrotis exclamatoris, 92
 Ailantus, the, 162
 Aira caryophylla, 303
 Alders, cut-leaved, at Wymstay, 250
 Alexandra Palace Rose show, 45
 Allgrove, Jesse, death of, 252
 Allium Karataviense, 231; pedemontanum, 6, 350; pulchellum, 215
 Allotments, orchard, 456
 Aloes, American, in Ireland, 521
 Alouca scabrinuscula, 232
 Alpine plants, 304; and rockeries, 144; 370, 393, 416; at Edinburgh, 111; at home, 88; culture of, 58; painted from Nature, 545
 Alternantheras, 262; treatment of, 256
 Amaryllis, a field of, 45; Acramani, 194; 216; longifolia alba, 124
 Amaryllises as decorative plants, 66
 Amelanchier canadensis var. alnifolia, 119
 America, Eremurus robustus in, 67
 Odontoglossums in, 248; Orchids in flower in, 480; Potato crop in, 206; the Moss Pink in, 192; gardening in, 551
 American Apple, a good, 447
 American Botany, contributions to, 193
 Ammoniacal fount, 349
 Ampelopsis Veitchii, 320, 414; at Frogmore, 369
 Anacheris Alsinastrum, 545
 Anactochili, 571; at home, 66
 Andromeda arborea, 383
 An-trosace Laggeri, 194
 Anemone Honorine Jobert, 325; pal-mata alba, 4; the white Japan in the wild garden, 57; vitifolia, 215
 Anemones, French, single and double, 111; in the south of France, 201
 Angers, the crops in, 45
 Angreum Chailluanum, 353; citrarium, 81, 105; Ellisi, 81; eburneum, 547
 Anguloa eburnea, 165, 190, 227
 Annals and their culture, 211; Messrs. Carter's, 7; spring-flowering, 158; winter-flowering, 188
 Anemethca cruenta, 195
 Anemone arvensis fl.-pl., 555
 Anthracis viscosa, 559
 Anthurium Lindleyi, 275
 Antigonon guatemalensis, 547
 Antirrhinums, seedling, 276
 Aphelandra cristata, 384
 Aphis, Auricula, 357; the woolly, 370; and parafina, 303, 334
 Aponogon indoors, 300; spathaceum var. junceum, 299, 326
 Apples, good American, 447, 470; Australian, 433, 471; Cox's Orange Pippin, 333; Loddington Seedling, 202, 471; Lord Suffield, 255; new, 44; Newtown Pippin, 501; Stone, 19; the Pennock, 544; Warner's King, 348; White Pippin, 447; orchard, 211; trees, healthy, in cold climates, 239
 Apples, blighted Keswick Codlin, 44; Canadian, 471; for market, 325; in Kent, 209; keeping, 290; Strawberry-coloured, 541; thinning, 470

Apricot branches dying of, 136, 202
 Apricots, a word about, 317; for October, 372
 Aquatic, a pretty but troublesome, 89; hardly at Kew, 81; indoor, 279;
 Aquilegias, 264; in the north, 285
 Aralia Sieboldi in flower, 447; spinosa 295
 Araucaria imbricata in Germany, 290
 Araucaria seeds, sowing, 474
 Arboretum, Glasnevin, 460; the Arnold, 339
 Arbours, plants for, 450
 Architecture, street, 500
 Ardisia Oliveri, 216
 Arca Alica, 416
 Arenaria baccarica, 32
 Argemone bulbosa, 92
 Argemone hispida, 231
 Aristolochia floribunda, 207; ringens, 216, 335
 Arnebia, chioides, 231
 Arthrotaxus selaginoides, 472
 Artichoke, Jerusalem, the, 550
 Arum Lilies in water, 508
 Arundo conspicua, 162; mauritanica, 353, 447
 Ascut Nurseries, Heaths at, 66; Roses at, 64
 Ash, early leafing in the, 86, 122; the flowering, 49; in Hertfordshire, 118
 Ash wood, and its uses, 506
 Asparagus Beetle, 233, 357
 Asparagus, age and strength of, 170; an error as to, 26; ashes for, 545; "belt," 27; carriage of, 250; choosing, 169; comparison between Dutch and Argentinian, 279; culture of 163, 223, 249, 269, 292, 312; cutting, 27; different methods of growing, 269; distance apart, 170; Dutch, 169; dying from wet, 340; early, 168; form of ground for, 170; French, 349; gathering, 249; green, v. white, 9; calendar respecting, 312; in America, 359; keeping fresh, 250; late, 168; manuring before planting, 193; M. Parent's machine for bundling, 313; neglected, 404; packing for market, 250; planting, 91, 169, 223, 522; Smalley's Early Defiance, 379; soil for, 169; sowing in the open ground, 271; treatment of young plants, 223; un-earthing, 219; utility of earthing up, 249, 274; varieties of, 168; decorative species of, 549
 Aspen leaves in autumn, 261
 Asplenium longissimum, 17
 Assegais, 50
 Asters, China, 276; autumn flowering, 320
 Aster dumosus, 394; trinervis, 394; Townsendii, 163
 Athole woods, the, 204, 217
 Athyrium Filix-femina, 113
 Aubrietias, 295
 August, Rhodolendrous in, 116; Rose show in, 81, 135; woodland work for, 194, 113
 Auricula aphid, 255, 357; gossip, 213, 234; insects, 89, 145, 252
 Australian Apples, 433, 471
 Australian Grass trees, 45
 Australian terrestrial Orchids, 247
 Automatic builder, 51, 132
 Autumn, Aspen leaves in, 261; Blue Berry, 250; Crocuses, 301
 Autumn-planted Potatoes, 447
 Avenae, a gap in the, 80; a long, 491
 Avenae, Rose, 377
 Azalea amena, 122; Empress of India, 43; hardly, 59; group of new, 242
 Azolla caroliniana, 501; pinnat, 132

B.

Babianae, culture of, 247
 Bags for fruit gathering, 372
 Baker's, Mr., Roses at Norwich, 82
 Bamboos, Riviere on, 524
 Bananas, 543; Californian, 404; culture of, 24
 Baneberry, common, 112
 Basket plant, Russelia juncea as a, 63

Baskets, hanging, 138, 229
 Batatas paniculata, 127
 Battersea Park, 460; Alpine garden in, 193; carpet bedding in, 194; flower gardening in, 194; sub-tropical beds in, 193
 Bauera rubioides, 297
 Bauhinia tomentosa, 446
 Bayfordbury, the Ellewiss at, 215
 Beardless Irises, 558
 Bearwood, 53
 Bed, a fine sub-tropical, 556
 Bedding at Heckfield, 461; shrubs for, 451
 Bedding plants, distribution of, 342; new, 343; notes on, 367
 Beds, mixed herbaceous, 325
 Bedford, weather at, 521
 Beech, the, as a shelter tree, 165
 Beech trees in Hertfordshire, 117; remarkable, 338
 Beet, Chilian, 325
 Beetles, 72
 Bezonia, Fuchsia-like, round an arch, 306; Martiana, 309; peruviana, 529; Reine Blanche, 45; Stanstead Rival, 159
 Begonias, 115; at Chiswick, 236; at the Stanstead Nurseries, 112; Continental, 524; losing their leaves, 450; new tuberous-rooted for 1879, 478; seedling, 148, 262; tuberous, 6, 60, 194; wintering ditto, 522; winter-flowering, 520
 Belgium, new winter garden in, 370
 Bell-flower, the broad-leaved, 233
 Belpoperone oblongata, 319
 Bennett's pedigree Roses, 99
 Berberidopsis corallina, 196, 455
 Berberis Darwini, 384; in towns, 338
 Berries, scarcity of, 542; autumn wild, 571
 Billbergia Moreli, 415; vittata macrantha, 529
 Billiardiera longiflora, 205, 250
 Birch, Weeping, 260
 Birds' nests in plant houses, 92
 Birds and seeds, 9; utility of, 477; and fruit buds, 533
 Bitton-holes, 432
 Blackberry, the Lawton, 211
 Black Currants, 239; pruning and training, 254
 Blatta orientalis, 20
 Bletia hyacinthina, 416
 Blistering of Peach and Nectarine leaves, 53
 Blue Cornflower, the, 57
 Bœconia cordata, 124, 238; japonica, 235
 Bog, artificial, 318
 Bog Bean, the, 215
 Bog plants, cultivation of, 153
 Bolders setting, 545; horticultural, 463
 Bollea coelestis, 81
 Bomarea Carderi at Pendell Court, 216; oligantha, 369
 Bonaparte juncea in bloom, 196
 Bones as manures, 498
 Boats, waterproofing, 450
 Boragifera market, 36; white flowered, 67
 Borago officinalis, 67
 Border Polyantheses, 303
 Boronia megastigma, 66; 498
 Botanical and horticultural literature, Chinese, 63
 Botanic gardens, Cambridge, 341; Graz, 276; Dublin, 25; Germany, 127; future of our, 25; Mauritius, 551
 Botany, American, contributions to, 193
 Bougainvilleas at Monaco, 4
 Boussingaultia baseloides, 369; at Bitton, 334; tubers of, eatable, 369
 Bouvardia Humboldtii corymbiflora, 329
 Bouvardias at Clapton, 505; at Wortley, 309; cool system of growing, 303, 415; in heat, 399; culture of, 438
 Box, substitute for, 71
 Bracken, transplanting, 115
 Bractens, the, 245
 Bramble, the white-stemmed, 446
 Brassavola Dierhiana, 275
 Braxoa geminiflora, 197
 Briers, Roses on, 479; raising seedling, 539

British Museum, library of, 405
 Brodiaea, twining, the, 80, 112
 Broccoli, preparing for winter, 265; laying, 327; purple, 327; Sutton's Late Queen, 477
 Bromelia bimoti, 93
 Browallia elata, 471, 504, 540; in open borders, 326; grandiflora, 190
 Browallias, 185
 Brunsvigia Josephine, 320
 Bulder, the automatic, 51; 132
 Bug market, 544
 Bulb beds, permanent, 526
 Bulb garden, 527
 Bulbs, Hyacinth, 500; potting and planting, 389, 438; winter flowering, 331
 Bulbous plants, American 471
 Bulbophyllum Beccari, 437
 Bullaces and Damsons, 254
 Burbridgea nitida, 196, 216
 Burnham Beeches, 45, 260
 Button-hole, the gold digger's, 150
 Byfleet, hardy plants in flower at, 59, 215
 C.
 Cabbage moth, 251
 Cabbage sprouts, 27
 Cabbages, 162; Daniel's Defiance, 24; at Chiswick, trial of, 154; early, 200; improved, 250
 Caeti on rocks, 109
 Caladium, Portuguese, 65
 Calamns densus, 358
 Calandrinia nitida, 196
 Calceolaria Golden Gem, 286
 Calceolarias, 463; propagation of, 338
 California, notes from, 100
 Californian Laurel, the, 197
 Calliandra terebinthina, 6
 Calliandra purpurea, 521
 Calochortus Benthani, 6; venustus, 59
 Calycanthus occidentalis, 205
 Camassia, white, 404
 Cambridge Botanic Garden, 341; U.S.A., 500
 Camellias in the open air, 142; planting out, 66; seedling, 425
 Camomile for market, 35
 Campanula latifolia, 233, 258; patula, 232; pyramidalis, 326; pyramidalis as a border plant, 124, 298; Rainieri, 81
 Canadian Elder, the, 197
 Canadian forests, 307
 Canadian Moonseed, the, 194
 Candytufts in wet seasons, 166
 Canterbury Bells, 124, 293
 Capsicum in market gardens, 11
 Carex nemoralis, 296
 Cardinal-flowers, 432
 Carex japonica variegata, 555
 Carludovicia Drudei, 207
 Carnation, classes of, the, 123; Coronet, 169; enemies of, the, 123; Heatherbell, 139; La Belle, 306; properties of, the, 123; the Queen, 94; modes of raising, 122; in winter, preserving, 450; and Picotees, 239; and Pinks, 122
 Carpet gardening, Sir J. Hooker on, 461
 Curse of Gowrie, Yuccas in the, 251
 Carya oliviformis, 544
 Catalpa speciosa, 461; syringefolia, 290; the dwarf, 470
 Caterpillar, Gooseberry, 72, 115
 Cattleya Domini, 521; labiata, 415
 Cauliflower, Autumn Giant, 391; Eclipse, 465
 Cauliflowers, 378; cutting, 27; early, 111
 Ceanothus Arnoldi, 201; azureus, 205; Gloire de Versailles, 471
 Cedar of Lebanon, 94, 499, 523
 Celery all the year round, 24; in market gardens, 11
 Celery fly, 173, 229; maggot, 569
 Cellars, Mushroom culture in, 114
 Cement, elastic waterproof, for protecting wounds on trees, 219
 Cemeteries, planting, 432
 Centennial Potato, 267
 Central Nevada and adjacent regions,

- forests of, 101
 Century plant, a large, 298
 Cercocarpus ledifolius, 102
 Cerechiphyllym japonicum, 543
 Ceterach as an edging plant, 392
 Chamelocrea glaucifolia, 415, 437; Hartwegi, 67
 Chelsea, Gloriosa Planti at, 196; Lilies at, 196
 Cherry, a new, 41; Early Rivers, 59
 Cherry orchard, a, 110
 Cherry Plum, 237
 Cherries, fine, 163; Morello, not ripening, 522
 Chelsea Lily bed, a, 31
 Chestnut tree at Tortworth, large, 439
 Chestnut trees in Hertfordshire, 118
 Chicory for market, 34
 Chillies in market gardens, 11
 Chili Strawberry, 55
 Chimonanthus fragrans, 186
 Chinese botanical and horticultural literature, 63
 Chinese Primulas, 572
 Chionodoxa nana, 329
 Chirita sinensis, 149
 Chiswick, Begonias at, 236; Grapes at, 429; large Vinery at, 164, 446; rock plants at, 89; Roses at, 220; trial of Cabbages at, 154
 Chloride of lime, 336
 Choretis glauca, 481
 Christmas Roses, 508; in pots, 483
 Christ's Thorn, 206
 Chrysanthemum frutescens, 656; M. Lemoine, 569
 Chrysanthemum show at Liverpool, 476
 Chrysanthemum societies, 370
 Chrysanthemums, 563; training, 548
 Chrysanthemums at Slough, 447; at Stoke Newington, 492; at the Aquarium, Westminster, 461, 473; beauty of, 501; culture of, 14; dwarf, 394; early, 320, 342; effect of frost on, 471, 481; green fly on, 382; in the Temple Gardens, 446; standard, 505; at Penthos, 480; Japanese, 303, 492, 502
 Churchyards, autumn flowers in, 212
 Cineraria maritima, 555
 Cinerarias, 463; blue, 320
 Cistuses, the 419, 431, 453
 City, gardening in the, 372
 Clapton, Bouvardias at, 505
 Clarkias, double, 33
 Classification of Grapes, 423
 Clematis lauginosa, 150; the yellow, 566
 Clematises, a group of new 128; at Woking, 256; propagating, 404; second pruning of, 340
 Clivanthus Dampieri, 331
 Climate of the Riviera, 546
 Climber, a fine-leaved, 446; the common hop as a, 143
 Climbers and wall plants, 72; conservatory, 133, 237; for trellis work, 274; ornamental, 214; stove, 535; Roses as, 141
 Clintonia pulchella, 346
 Clusches, 493
 Clove Carnation, 138
 Clumber, Felargoniums at, 367
 Coal-ash walks, 222
 Cob-nut failure, 254
 Cob-nuts in Kent, 210
 Cocculus indicus, 446
 Cockroach or blackbeetle, 20
 Cocos elegantissima, 353; Weddelliana, 437
 Colax jugosus, 77
 Colchicum family, 320; speciosum, 319
 Colchicums, 301; at Tooting, 341
 Cold, extremes of, 557
 Colours, Dr. Brushfield, 94; Hendersoni, 257; James Barshaw, 94; majestica, 353; tricolor, 159
 Colewort, rosette, 9
 Columbines, 264, 285
 Colutea Poccocki, 205
 Combreum purpureum, 65
 Commission, illicit, 341
 Condrobium ramonoides, 148, 159, 193
 Conifer, hybrid, 542
 Conifer seeds, 72
 Conservation of woods, the, 165
 Conservatory climbers, 133

D^R. R E G E L.

EDUARD REGEL was born August the 13th, 1815, at Gotha, where his father held the post of professor and military preacher. He was educated at the Gymnasium, and was afterwards apprenticed at the Grand Ducal gardens at Gotha, attending, however, at the same time special classes instituted for languages, mathematics, and drawing. He acquired a full and thorough knowledge of Latin, which was afterwards of great help to him in many ways. Three years afterwards he entered the botanical gardens at Gottingen, then under Professor Fischer's direction. There he was permitted to attend the lectures of Professors Schrader and Bartling. In 1837 he went to the botanical gardens at Bonn, then under Inspector Sinning, and remained there till 1839. Bonn was then an excellent school for gardeners, the cultivation of plants being there carried on on rational principles. There he studied the local flora, and produced, in company with Schmitz, his "Flora Bonnensis." In 1839 he entered the botanical garden at Berlin, under the direction of Otto, and there he soon had occasion to develop his literary talents in the "Gartenzeitung" of Otto and Dietrich. One of his principal contributions to that periodical was a long paper on "Die Hauptmomente der Gartnerie durch Physiologie begründet." To the "Proceedings of the Horticultural Society of Prussia," he contributed his "Cultivation and Description of all the Ericas then existing in German and English gardens," a work still valuable, and of which a revised edition appeared in 1843 at Zurich.

In the Berlin Botanic Garden at that time the position of the under gardeners was more independent than in most places, every one of them having charge of a certain department, for which he was entirely responsible. Regel took to hardy herbaceous plants. In 1842 he was appointed botanical gardener at Zurich, and was instructed to re-organise the botanical garden there. In 1843 he founded the "Schweizerische Zeitschrift für Gartenbau," in company with Professor O. Heer, and afterwards became sole conductor of that periodical, changing it in 1852 to his still existing "Gartenflora." Along with Professors O. Heer and Naegeli, then Directors of the Zurich Botanic Garden, he founded, in 1852, the Swiss Horticultural Society, of which he was elected president. He also lectured at the University, and took, in 1855, the degree of doctor.

When, in 1855, the director of the Imperial Botanic Garden at St. Petersburg, C. A. Meyer, died, the leading authorities had the good sense to choose for that post a man who was at once a good botanist and a good gardener, a combination which REGEL possessed in a high degree; his "Gartenflora" exemplified his skill as a botanist, and the flourishing condition of the Zurich Garden gave ample proofs that he was a good gardener. During his thirteen and a half years' stay at Zurich, he formed many connections with foreign countries, and introduced and distributed many new plants; he also devoted part of his time to experiments in hybridising, especially as regards the genus *Gesnera*, the result of which he afterwards published in his work "Plants and Plant-life in Relation to Practical Gardening." The Zurich Garden was not endowed with large funds, but REGEL—by, in a practical way, increasing and sending out new plants, and also by frequent exchanges—very soon gained for it a prominent position amongst botanic gardens. In the same way he continues in his now much more important position to distribute liberally to European gardens the novelties which arrive in great quantities at St. Petersburg.

When first he went to St. Petersburg he observed many things that needed changing, but during the first few years he was, in spite of his nomination as scientific director, prevented from doing much, as every effort to do anything was dependent on the Administration. After a time, however, he was nominated *Kollegienrath* and *Botanicus Primarius* and, under Trantvetter's Administration, got freedom of action; and when Trantvetter retired he became Director-General of the Garden. By and by he altered to advantage the arrangement of the plant collections, had the houses rebuilt, and most of them heated by hot water. As far as was possible, he placed his plants in groups, each representing a separate flora, such as that of St. Petersburg, Siberia, Caucasus, North America, &c., and at the same time he laid out and embellished the park adjoining the botanic gardens. Innumerable plants, especially from the Central Asiatic dominions, were introduced and described by him, and most liberally distributed to all foreign botanic gardens and nurseries. He laid out the Admiralty Garden with much taste and judgment, and improved that around the statue of the Empress Catharina. He rendered also great services to Russia, in advancing, by his writings and example, the cultivation of fruits and fruit trees, and founded for this purpose a private pomological garden, and a garden for acclimatising purposes, the importance of which will be understood when it is stated that they cover about 70 hectares or about 175 acres. A difficult undertaking was the foundation of the Russian Horticultural Society in 1858, but in this he succeeded, and has been since that time its vice-president. On his recommendation, that Society ventured to hold an international exhibition in 1869, which turned out to be a brilliant success.

As to his literary works, he is the author of the "Flora of Siberia," "Turkestan," and the "Russian Deudrology." Numerous contributions to periodicals and in the form of pamphlets also attest his zeal and energy in this direction. He is a Councillor of State, with the title of Excellency, a rank which he has won entirely by his talents, perseverance, and energy. He is just and amiable in all his dealings with others, and steadfast in his friendships.

THE GARDEN.

VOL. XVI.

GLASS V. CANVAS FOR TULIP BEDS.

WITH several old florist friends, as with myself, the thought of blooming Tulips under glass instead of canvas is not new. Years of watchful culture of a favourite flower so exclusively under its owner's charge as a florist's flower is enable us, among other advantages, to foreknow what more can be done for its welfare and improvement than we have accomplished yet. Thus a new step in cultivation, where the nature of the plant is our guide, need not be dreaded as a false one. The two great enemies of the Tulip are wet and wind, and though our old-fashioned canvas apparatus is a protection against these, yet we are ripe for believing that there is a more effective and more beneficial shield in glass. Little as we have ever feared winter frosts for Tulips, I did not expect that we should so serenely smile at its iciest grip till after the experience of last winter. The Tulips here were planted early in November in their two parallel beds, each 48 ft. by 4 ft., and were perfectly without shelter till late in March. Before the poor bulbs could root deeper than 1 in. they were frozen solid, and by degrees the soil beneath them, till the beds, which are nearly 1 ft. above the ground level, were hard as rock. In this imprisonment the bulbs remained for many weeks with fibres unable to move during those very months in which they would naturally have been in most active growth. It was long after the thaw set in before they were released, and yet the foliage, though several weeks behind time, unfolded without one injured leaf, and in due time the buds rose up as if nothing unusual had occurred, although here and there the petal tips of a few sensitive varieties such as Kate Connor, Friar Tuck, and old La Van Dikken afterwards showed signs of frost-bite. It was marvellous to see how no tissue had been disorganised, nor cell of colouring matter ruptured in the most delicate flash of pencilled feather-

ing; hence the hardiness of the Tulip is set beyond dispute, at least in situations not too wet. In reply to a request to state what I think of glass in the place of canvas for Tulips, my answer is that I would not for any consideration let them dwell in tents again.

Shelter from fierce sunshine, beating rain, and tearing winds is imperative for the tall florist Tulip, with its large broad petalled cup and exquisitely flamed and feathered petals, but the moment the canvas is set over them a gloom falls on them, and that which is a protection to the flowers becomes an injury to the rest of the plant. The diminished light begins to draw the stalks and has an effect for evil upon the foliage, so intimately connected not only with the development of the bloom, but also with the formation and calibre of the next year's bulb which the plant while above ground is busily elaborating from the tiny germ first begotten within the old bulb while dormant in the preceding summer. Canvas, indeed, is but a cumbrous luxury, and to be effective and harmless is only for those who, for their Tulips' sake, could watch the sunshine, and the shadows, and the passing thunder-storm, and withdraw the shelter when there was not danger. But it is not given to the main of us to be such leisure folk, and to be at hand in the garden to trim our canvas to the changeful weather.

The advantages of a glass protection are simply commensurate with every need which our perplexing British climate creates. Glass is the magic extractor of all that is welcome in this Bitter-sweet. And need I say how great temptation there may be in this adaptable protection to seek change of floral scene in other florists' flowers; and after the Tulips have had their bright day, and we have seen again the pictured petals with their inimitable work in white and scarlet, gold and black, to follow up the glories of the Tulip bloom with

the beautiful change, say of the Carnation, Picotee, and Chrysanthemum. For my own part I have not yet reaped all the benefits of the alteration I have adopted. The bloom has been uninjured and in time for the Royal National Show, which in this cold locality I have for years together been unable to catch, and only hoped for in exceptionally kindly springs.

The foliage has been good, but I have yet to see the bulbs that are the harvest of it all, but contemplate the gathering in with a feeling that it is well with them. Of course Tulips shut down under glass would not thrive. The plant is hardy and must feel the open air; but it will occur to Tulip growers that their favourite is all the better suited for this protection in being naturally free from insect pests that affect greenhouse plants. I never saw green fly upon a Tulip leaf, though, oddly enough, a group of vigorous aphids may be seen upon the young sprouts in October, when the stored bulbs have been kept in quarters too confined. Red spider cannot affect it, because all leaf growth is over before the heats of summer. No grub or caterpillar seems to care for Tulip leaves or buds. Birds that will ruin our Carnation and Polyanthus buds touch not these. The blooms are no congenial haunts for earwigs, though they are prisons for many a bee. Slugs of divers interesting varieties will glide over the glaucous foliage of the Tulip; and, as smitten with a too rare resolve to be honest for once, will pass on without a stolen taste. A last thought in favour of protecting the bloom with glass is that it may be made water-tight, and so save the flowers from being pitted with the ruinous marks that rain through a rent in canvas, or even spray from a thunder shower beating through may create—mischances which require, under old systems, an extensive arrangement of hand-glasses in readiness for valuable blooms. Of course, too, it is only the south side glass that requires a sunshade; the north continues always open to the clear day, and keeps up a very valuable supply of light. F. D. HORNER.

Kirkby Malzeard, Ripon.

THE FLOWER GARDEN.

ROCK V. CARPET GARDENING.

“GLORIOUSLY beautiful!” No other expression is suitable when we look down from a broad gravelled terrace on a well-kept and carefully arranged garden laid out in carpet bedding. And yet, why that sigh? Is it not enough to have the eye delighted with the bright tints and gay colouring blended skilfully together so that the whole is not too gaudy, but softened with the exquisite neutral tone which is allowed to predominate sufficiently to prevent anything like vulgarity in a too striking contrast? Is it not enough to look and wonder over the skill which has adapted that intricate mosaic of unruly plants so that it presents to the eye an even surface of varied pattern and scroller? No, it is very beautiful; and we should be very sorry to see the style given up—as under the powerful influence of fashion it inevitably will be sooner or later—but, nevertheless, it does not satisfy; it is uninteresting. Yes, that is the grand fault; you look at it and admire it, and then there is nothing more. In the varied beauties of a lovely scene in some Devonshirecombe, or on some wild rocky moorland there are poetry and feeling, and the mind is stirred, and even an individual flower may have power to excite in some the same sort of emotion which Linnæus felt as he threw himself on his knees and thanked God for the beauty of the wild Gorse, but there is no poetry in the carpet garden. The artificial work of the artistic cultivator is too manifest in the trim neatness of the carefully

wrought design. It is after all lowering the dignity of flowers and beautiful leaves to treat them so. Nevertheless let them be. We at all events recommend our readers to have in addition a garden that will interest.

But how is this to be done? First, get some stones, the very largest you can find; heap them up in as irregular a fashion as possible, with plenty of earth between them, and taking care that they are sloped well back and therefore are not in the least either like a wall or a building. Let the soil consist largely of leaf-mould, but have also a place where there is some corner in which you can put peat. Put the whole rockery right in the eye of the sun; there will still be shady nooks enough for those few things that like it. In one corner manage to plunge half a barrel (if you are anxious to do things economically, half a petroleum oil barrel, costing 2s., will do well), fill it up loosely with stones, peat, leaf-mould, and fresh upland soil, and cover the rough upper surface with Sphagnum Moss, then pour water over the whole till it is full and overflowing; this will be a bog garden of minute dimensions certainly, but nevertheless interesting.

You are now prepared for planting. To judge from the answers which one sees from time to time in the column headed “Correspondence” in the various gardening papers, the best thing usually done is to write to some paper for a list of plants suitable for a rockery, &c. Now we do not admire this plan. On the contrary, we recommend that nothing should be put into the rockery without having some special interest attached to it. This may be either in the plant itself or in some association connected with it. It may be in many ways in the plant itself. Find out its name and why it is so called in English and in Latin; the country in which it grows wild and the sort of locality it loves to haunt; the botanical construction and its consequent relation to other plants; in fact, find out all the plant lore about each plant you put into the rock garden, be it little or big. But the associations connected with it may make the plant far more interesting. “That beautiful bit of Grass of Parnassus,” you may say to yourself, “came from the loveliest of Swiss valleys near the Rosenlauri Bad”; and the whole beautiful scene of snowy mountains and glaciers and rushing water and Spruce Fir will come up again before your eyes, as it does before the eyes of the writer at this moment. You will seem to hear the echoing horn coming towards you with wild strains of the *Ranz des Vaches*. “That bit of Gentian grew once at the Grimsel, and I found this little treasure of Saxifrage near the Handeck Falls.” Associations of that sort may be indefinitely multiplied in connection with the rock garden. But another interest still attaches to the time of the year in which many a flower before the delicate bedding plants leave their glass shelter.

And, again, there is another interest in the delicate beauty which many of them possess. *Ramondia pyrenaica*, for instance, has a delicate tint of lovely pure grey, and is altogether one of the most beautiful plants which can be cultivated, and it steed with perfect impunity the very severe frost of last winter. Another source of interest which may commend itself to some is the difficulty of cultivating well some of the best Alpines, *Gentiana verna*, for instance, which in itself keeps up the interest in those particular plants and makes a fine specimen a source of triumph.

The rock garden may be very small, and yet deeply interesting, if there is some special association with every plant in it. We recommend that it should not be made too large at once, but grow with the plants which are procured to fill it; for a rockery without plants is neither interesting nor pretty. Those who have not tried it will find that they have within their reach, even in a small town garden, a source of unfailling

interest which will not flag, but grow and increase, as they add more and more specimens and varieties to their rock garden. In a small space not more than 6 ft. square it is quite possible to have a collection of not less than a hundred different Alpine plants and Ferns.

J. L. S.

OMPHALODES LUCILIE.

Of the numerous additions which we have had of late years to our lists of hardy flowers perhaps none have been more universally admired than the subject of the accompanying engraving. It belongs to the Borage family, which furnishes us with so many beautiful border flowers, the majority of which are at the present time in full beauty. Though its flowers lack the deep azure blue of its pretty congener, the spring-flowering *Omphalodes* (*O. verna*), there is something in their pale porcelain blue tint which changes to a pinkish hue that is quite unlike anything which we have amongst hardy flowers, and this, combined with its handsome glaucous foliage and the graceful creeping habit of its slender branches, which throughout the greater part of the spring and summer months bear a copious supply of blossoms, has elevated it to the rank of plants that cul-

Omphalodes Lucilie.

tivators like to place in the most select spots in the rock garden. Its perfect hardiness, too, much enhances its desirability, for it has withstood the past winter with impunity, though quite unprotected. It succeeds well when planted in a border or on a rockery, where its branches hang over the ledges, but the place must be thoroughly drained, for though it requires abundant waterings during the growing season, it is very impatient of stagnant moisture at the roots or about the crowns. Slugs, unhappily, are particularly fond of its foliage; therefore the plants should be guarded against their attacks, and for this purpose strips of perforated zinc about 3 in. wide, and bent so as to form a ring round the plant, will be found to be as effectual as any plan that can be adopted. It may be readily propagated by division or by seeds, which in some seasons it develops freely. It is very successfully grown in Mr. Wheeler's nursery at Warminster.

W. G.

MIXED FLOWER GARDENING.

The present melancholy condition of the flower beds in the Regent's Park forms a strong argument against pinning one's faith exclusively to the modern custom of bedding out to the neglect of the old-fashioned and more natural system of cultivating hardy annuals and perennials. Owing to the long winter through which we have passed, the usual bedding out operations could not be performed until the season had far advanced, and the consequence is that these beautifully-laid out flower beds, the plants in which generally make such a brave show about this time of year, present a pitifully

stunted and meagre appearance, and that, too, when so many gardens, situated in less favourable positions, but planted with both old and new-fashioned hardy annuals and perennials, have been for some time past glowing masses of vigorous life and brilliant colour. Bedding-out plants most undoubtedly have a special beauty of their own, but the miserable, half-starved subjects in the Regent's Park ought to teach cultivators that, in exceptional years like the present, we must not rely on them solely for a spring and summer display. A good selection of hardy annuals and perennials scattered about these beds would now have worthily replaced the sickly *Pelargoniums*, *Echeverias*, and *Pyrethrums* with which these borders are planted and have prevented them from bringing such discredit on the bedding-out system, which, after making all allowances, certainly has its merits in spite of all that has been said against it. It is both interesting and instructive to turn from the art of Regent's Park to the nature of Hampstead Heath. I have been familiar with every nook and corner of this grand wild garden from year's end to year's end for five-and-twenty years, but I have never seen such wealth of leaf and flower as it presents this summer. This may be ascribed to two causes—the lateness of the season and the wholesome check put upon the destructive habits of the sandboy and the destructive Cockney by the beneficent action of the Metropolitan Board of Works. These are no longer allowed to work their wicked will on one of the fairest spots about London by converting Grass-clad hillocks into sand-flats, or by ruthlessly burning or uprooting Furze, Broom, and Fern. Dame Nature has once more resumed her sway over this charming spot, and the whilom sterile plain on the west of the road leading to the "Spaniards" is slowly becoming covered with verdure. The golden-blossomed Broom is making a most gorgeous show, and the duller glow of the Furze is following closely in its footsteps. As a true wild garden harmony in green and gold of many tones, blended with patches of blue *Veronica* and *Polygala*, white *Galium*, and ruddy-flowered *Sorrel*, with gleams of ochreous soil showing here and there amongst the green turf and tawny-tipped *Bracken*, Hampstead Heath in the pleasant month of June affords the beauty-loving eye a display of colour which the highest art may emulate, but can never equal.

C. W. QUIN.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Wintering Gladioli Out-of-doors.—What Mr. Divers states (Vol. XV., p. 493) respecting the strength of his Gladioli that had been left out during the winter bears out what I asserted some time back concerning not only Gladioli, but similar plants, and I am convinced that if Gladioli were allowed to remain in the ground instead of being subjected to the unnatural process of drying and storing, that the majority of them would be all the better for being allowed to take care of themselves. In planting, however, in soils that are inclined to be stiff and wet, it is necessary to make proper preparation for them by affording a little drainage underneath, which may be done by making use of any refuse material at hand, such as finely-broken bricks or cinders. These should be placed low down in order that the plants may have plenty of depth in which to grow; and in filling up the holes it is always advisable to work in with the soil plenty of grit, such as the scrapings of roads or some sharp, clean sand, either of which will keep the bulbs clean and prevent them from rotting. Thus treated, most kinds will stand almost any weather, for if they are tolerably dry and comfortable, frost has but little effect on them; but, in order to render matters safe, it is easy to cover each patch when the borders are cleared in the autumn with a handful or two of Cocoa-nut fibre. This forms an efficient protection and is not unsightly at any time, nor liable to be scattered or blown away by winds in the way in which any lighter materials would be. There is one thing that should be borne in mind when planting Gladioli or other bulbs of a like character intended to be left out during the winter, and that is, to plant them deeper than is usually done, the tendency being rather to raise themselves than get lower. If those having Gladioli will try a portion of their plants in the ground where they grow, and compare them at the end of the summer with others that have been lifted, they will soon see how superior the former are to those lifted, a circumstance not to be wondered at when we consider how much the stored bulbs lose in weight from shrivelling, especially if they happen to be kept a little late in the spring.—S. D.

Seedling Petunias.—These are extremely useful both for flower garden and conservatory decoration in summer, and being so easily raised are well adapted for amateurs whose amount of glass is generally limited. The seed should be sown in heat in February, and the young plants, if pricked off into boxes, will acquire a good size by May for furnishing flower beds. A few, too, of the striped and double kinds, if potted on as they require it, will make useful specimens for the conservatory by midsummer. Petunias have been

so carefully hybridised and selected during the last few years that the produce from seed may now be relied on to yield really fine, well-marked flowers. We have some belonging to the grandiflora or large-flowered section now flowering, the produce of seed sown this spring, and the blossoms are exceedingly attractive, being large in size, richly marked, and fringed at the edge. A few stakes to support the side growths is all the training they require, and a rich light compost, consisting of loam, rotten manure, leaf-mould, and sand, suits them admirably. They should be carefully watered after being fresh potted, as if the soil gets sodden they are liable to rot off at the base; but when well rooted they can scarcely be over-watered, and when in bloom weak liquid manure will assist greatly in prolonging the display. Under good cultivation they are seldom much affected by insect pests, but if green fly attacks them fumigation with Tobacco smoke is the safest remedy, as the leaves, being downy, are liable to receive injury from dipping in solutions strong enough to destroy insect life.—J. GROOM, *Linton*.

Monkshoods in the Wild Garden.—Amongst tall and vigorous herbaceous plants few are more suitable for wild and semi-wild places than Monkshoods. They are hardy and robust enough to grow anywhere in shady or half-shady places. Their tall spikes, loaded with blue flowers, are very beautiful, as we can say from having seen them naturalised in shrubberies, where a few tufts were thrown out by accident amongst the soil in the autumn, and as they are rather short-lived in bloom and stiff plants, not quite so manageable as Delphiniums in the mixed border, they seem particularly well fitted for the wild garden. The annexed illustration shows the common Aconite in a Somersetshire valley in company with the Butterbur and the Hemlock. In such a place its beauty is very striking. As many of our readers know, some of the Aconites are very poisonous, so much so, indeed, that many people will not allow them a place in their gardens for this reason alone; places outside the garden seem best for them. The larger rich blue kinds and the blue and white one are very beautiful grown in deep soils, in which they attain a great height.

Eritrichium nanum.—I am glad to be able to tell you that I have two plants of *Eritrichium nanum*, which seem to me to be perfectly established on my rockwork without costing £100 (p. 492). It is true that I have not had them for a very long time, but they have both blossomed with me, and they have at least doubled in size since they were sent to me. No two plants in the garden look more happy and completely at home than these two specimens of *Eritrichium nanum* seem to be. I shall be much surprised and disappointed if they do not hold on well for a long time to come. The great thing is to cover their heads with a large piece of glass in the winter, while the sides are left quite open. I owe more success in keeping Alpine plants to this recommendation of your correspondent "W." than anything else. It is simply invaluable, and there is scarcely an Alpine (I have not yet tried Bog plants) which cannot be grown here by its aid.—H. EWBANK, *St. John's, Ryde*.

Pulmonaria saccharata grandiflora.—In the foliage of this large red-flowered *Pulmonaria*, as produced by the plants as soon as the bloom is over, may be found the characteristics of a hardy plant most attractive for summer bedding purposes. The growth rarely exceeds 8 in. in height. The leaves are long, somewhat lanceolate, with a rich green ground and densely marked with white blotches, thus bearing a close resemblance to the foliage of a *Diefenbachia* as respects markings. Strong plants of it will by the autumn cover a diameter of 18 in., and the foliage will keep fresh and clearly marked all through the winter. It would be specially valuable as an edging or carpet plant to a bed of Cannas, but it would be handsome and effective howsoever employed.—A. D.

Seedling Delphiniums.—One of the finest displays I ever saw is now being furnished by a bed of these 24 ft. long and 5 ft. wide. Unfortunately it is in the kitchen garden and in anything but a prominent position. The seeds were sown last spring and the young plants parted and set out about 1 ft. apart in September; in winter they were heavily mulched. The growth this season has been truly marvellous; some are now 6 ft. high. They vary in colour, size, and compactness of bloom, but as yet not a flower-stalk has developed itself which I can make up my mind to discard, while many spikes of bloom are truly magnificent and equal to any named varieties I ever saw. The seed was all home saved and gathered from the best sorts only. After this experience I shall never think it necessary to purchase any more named kinds.—H. M., *Bromsgrove*.

Bougainvilleas at Monaco.—At the Villa Walewski, Monaco, there is a wall about fifty yards in length, facing south, and extending by the side of the approach from the entrance lodge to the house. This wall at the time of my visit in April last was covered from end to end with the blooms of *Bougainvillea spectabilis*, *B. glabra*, and a light scarlet variety (the name of which I do not know); of these *spectabilis* occupied most space, and was, at least to my thinking, by

far the most beautiful, the colour when grown in the open air being darker and richer than that of those seen at home under glass. The dazzling effect of this wall was very striking, my attention being drawn to it from its appearance at a considerable distance off. *Bougainvilleas* at Cannes were almost killed by the severe winter, and scarcely showed any flowers.—J. H. W. T.

Sambucus laciniata variegata.—This beautiful variety of the Parsley-leaved Elder looks strikingly handsome on Grass, its beautifully variegated and deeply serrated leaves being very distinct. We have a bush of it with shoots quite green, others very evenly variegated, and others of a pale lemon colour, resembling that of the Golden Feather *Pyrethrum*. It is extremely useful for decorative purposes, as its lace-like foliage forms an agreeable garnishing for cut flowers or for table decoration.—J. GROOM.

ROSES.

THE CULTURE OF ROSES.*

Situation.—A place apart from other flowers should be assigned to them, if possible, sheltered from high winds, but open and not surrounded by trees, as closeness is very apt to generate mildew; where they cannot have a place to themselves, any part of the garden best fulfilling these conditions will answer.

Soil.—A most important item in their successful culture. That in which they especially delight is a rich unctuous loam, that feels greasy when pressed between the fingers. Where this is not to be had the soil must be improved; if light, by the addition of loam, or even clay, well worked in; where heavy, good drainage and the addition of coal ashes in small quantities will help it, but in such places draining is most important.

Stocks.—For standards (which are generally a mistake for non-exhibitors), the Dog Brier is the stock; dwarfs may be either (1) on their own roots, (2) on the Manetti, (3) on the seedling Brier, (4) on Brier cuttings. The first are a much longer time in making plants, and only some do well; 2, a very suitable stock for all soils, but apt to be too vigorous for weakly growers, and of late 3 has taken its place to a large extent, suits many varieties better, makes very strong roots, and does not throw up suckers; 4 is very nearly similar, and generally suitable for all soils. For Teas and Noisettes either 3 or 4 are unquestionably the best.

Planting.—November is the best month, but it may be done any time when the ground is in good order during the winter months. In planting budded plants place the point of junction beneath the soil, as the Rose will then make roots and the plant has a double chance. Mix some loam and well-rotted manure together, open a good-sized hole, and fill it with the fresh soil; plant firmly. Tea Roses should be protected by Fern loosely scattered among them. Shorten any very long shoots, and, if exposed to winds, secure the plants by short stakes.

Manuring.—Roses are strong feeders, and will take almost any amount of manure; pig manure is the best, except in hot soils, when cow manure is preferable; stable manure is generally available and good. Exhibitors generally apply a top-dressing in spring, but it does not improve the appearance of the beds; a good top-dressing may be laid on the beds in autumn, and be dug in in the spring.

Watering.—When coming into bloom, if the weather be dry, give a good drenching twice or three times a week; continue after blooming to prevent mildew. If greater size be required, liquid manure may be used. Syringe daily for green fly.

Pruning.—This may be done any time after the beginning of March, according to the season. Cut out all wood over two years old and all weakly shoots. Weak-growing kinds should be pruned hard, *i.e.*, down to three or four eyes; stronger-growing kinds may be left longer. Cut to an eye that points outwards, so as to keep the inside of the plant open. Teas and Noisettes require less cutting back; the tips should be shortened and the weak shoots cut out, and they should not be pruned until May. Use a good pruning knife in preference to a sécateur, as it cuts cleaner, and does not bruise the wood.

White-flowered Anemone palmata.—This pretty addition to early summer-flowering kinds of Anemones has all the characteristics of the original species, from which it differs only in the pure white colour of its flowers. We hope soon to see it in general cultivation, though at present it appears somewhat scarce. It is now in flower in the herbaceous ground at Kew.

* "Brief Hints on the Culture of Roses," issued by the National Rose Society.

THE PLOUGH IN THE GARDEN.

PROBABLY the day is not far distant when all large vegetable gardens in this country will be cultivated by the plough to a great extent, and spade labour, except for a few special subjects, will become a thing of the past. The use of the plough within the garden walls has been suggested pretty often within late years, but the suggestion has not been as yet received with much favour. One chief reason of this is that our kitchen gardens are at present so planned and arranged that the plough could not be used to good advantage. The system of dividing the ground enclosed into small plots or quarters devoted to both vegetables and fruit trees renders the use of the plough all but impracticable. Before it can be introduced successfully we must remodel our vegetable gardens, and there is no valid reason why that should not be done, when new ones are formed or old ones have to be altered. Plough culture would also entail larger gardens, for the close cropping system could not so well be followed; but that would matter but little, for the extra ground required would be cheaper than the extra labour incurred in spade culture. First of all, it would be necessary to get rid of the idea that the kitchen garden must be an ornamental as well as a vegetable ground. The proprietor must come to regard it in the same light as one of his Wheat or Turnip fields, and nothing more; and now with our spring, summer, and wild gardens this is not too much to expect. Gardeners would undoubtedly welcome the change, for the plough would save them much labour and anxiety.

The present system of cropping kitchen gardens is the cause of much waste of time and labour. For example, all main crops like Broccoli, Cauliflowers, Peas, Brussels Sprouts, Cabbages, &c., have mostly to be sown and afterwards transplanted, because perhaps at the time the quarters are not vacant to receive them, or that the time cannot be afforded to dig and sow the ground where the plants are to remain; but it would be better for all such subjects if they could be thus treated. Every gardener knows that all the Brassica tribe produce the best crops when the plants are sown where they are to grow, and that transplanting in most instances is attended with a check to growth if not worse evils, and hutting in Cauliflower, which is the bugbear of the Cauliflower grower, would be unheard of almost if transplanting could be abolished. Then the practice of sowing in beds and dividing every crop off from its neighbours entails an infinite amount of trouble, and is productive of weeds and filth; it is all ground that has to be kept clear to no particular purpose, and the same may be said of small plots or quarters. The more plots the greater the extent of useless margins, walks, alleys, and walk edgings, that have to be looked after. Reckoned up, it is simply astounding the extent of walks in some private kitchen gardens—gardens which the proprietors hardly look round once a year or more. The cost of producing kitchen vegetables and other crops for the house really does not represent more than a portion, and that the least, probably, of the cost of maintenance, the greater part of the labour expense being incurred in keeping and dressing walks and borders and vacant ground. Hence, too, it is that private gardens have got the name of being unremunerative; but as a matter of fact, vegetables, if measured by their actual cost of production, and not saddled with the extra expenses incurred for other purposes, are produced cheaper, as a rule, in private gardens than anywhere else. The fault lies in the plan of our kitchen gardens, which entail a certain degree of good order and dressiness, irrespective of the necessities of vegetable culture. A garden laid out with trim walks and miles of Box and other edgings and fruit trees and flower borders looks simply disgraceful if not kept tolerably well up to the mark at all points; but do away with the necessity for such keeping and no one expects it, and nothing appears to be wrong. Those who wish their kitchen gardens kept up in flower garden style have a perfect right to have their wishes gratified, of course, but, as a matter of fact, nine-tenths of our large private kitchen gardens are a shame to be seen. Ill-kept walks, worse-kept edgings, and untidy borders are a satire on the

style. Not long ago a certain horticultural society in the north took up the subject of kitchen gardens and offered a prize for the best plan, but nothing in the least original or better came of it, and the prizes were awarded to designs that were clearly faithful copies of the old style, and these same plans were afterwards published by a contemporary as commendable. If the plough is to be employed in the garden, therefore this state of things will have to be altered. What a gentleman will need for a garden in which to grow the whole of the main crops will be a piece of good ground from 3 acres to 6 acres in extent, according to the supply expected, and sheltered on the north-east and west sides by a belt of trees, and fenced to exclude game, unless he wishes to have it walled round. This piece should consist of one quarter intact, and at the most it need only have a boundary road running round the outer skirts of it. One portion of the ground might be set apart for the culture of small bush fruit (all fruit trees like Apples and Pears being confined to an orchard), and the bushes should be planted in straight lines right across the quarter. The remainder of the ground would, of course, be reserved for vegetables, and here all the Brassica tribe (including Turnips), Spinach, Peas, Beans, Carrots, Beet, Parsnips, Onions, and Potatoes, &c., could be sown or planted by the plough or seed drill in sections without a break or alley anywhere. The small French

farmers, some of whom have only a little piece of ground not so large as some English kitchen gardens, follow this plan successfully, as may be seen by any one travelling on the railways in France. Of course early crops could be grown on warm borders as at present, but these form but a fractional portion of the crops of a kitchen garden. Such a garden as we have described would, we submit, look much better and be much more easily managed than one laid out on the usual complicated plan. We shall probably be met with the assertion that ground worked by the plough would not be deep enough for many kitchen garden crops; but the objection will hardly hold good. No doubt a deep soil is beneficial, and there need be no difficulty about trenching the ground deeply in forming a kitchen garden, but the farmer has proved conclusively that as good root crops almost can be produced in the field as in the garden by intelligent culture, and that, too, where the soil is not very deep. One has only to point to the monstrous Mangolds, Beets, grand Potato, Turnip, Carrot, and Cabbage crops that are constantly raised as field crops in proof of this. It should be borne in mind, however, that very large vegetables are not always the best for kitchen use, nor preferred. On the contrary, moderate-sized samples are always preferred by cooks; and,

Monkshoods in the Wild Garden.

so far as this applies, the produce of the farm just suits his wants as well as that of the garden. Another point connected with kitchen gardens that it is needful to mention is the situation of the forcing and plant houses, which are generally placed in the kitchen garden, no matter how far these may be from the mansion, sometimes as much as a mile, entailing a long journey on the part of the proprietor or his friends when they wish to see the hothouses. Some portion of the forcing houses are best placed in or near the vegetable garden, but plant houses, Vineries, and Peach houses, &c., might advantageously occupy a more ornamental position in or near the pleasure grounds, and not too far from the house. They need not necessarily be in the vegetable field where the plough is used, at least, and their absence will leave that department free to be treated for its own special purpose. We believe the plough is employed in several market gardens about London, and it only needs an example setting to show what can be done with it in private gardens. Those who from any cause find their kitchen garden too expensive to keep up in the old semi-ornamental style, and yet wish to save it from becoming a half waste piece of ground, would do well to eradicate the unkempt walks and borders and turn the plough into it. A kitchen garden should at least be as cleanly and well cultivated as a farm, which is cropped at considerably less cost, and where this cannot be done something is wrong; but it is well known that hundreds of gentlemen's gardens are in this plight. C.

NOTES OF THE WEEK.

Allium pedemontanum.—Messrs. Backhouse & Sons, of York, have sent us a remarkably fine example of this bulbous plant which is without doubt the finest of all the *Alliums* in cultivation. It grows about 1 ft. high, and has deep green grassy foliage produced in tufts, from which arise slender flower-stems, terminated by a drooping umbel of bell-like blossoms of a deep mauve tint, and which last a considerable time in perfection. It is a native of the limestone mountains of the south-east of France and north-west of Italy.

Cycads at Kew.—The rich collection of these handsome plants in the Palm house is now well worthy of a visit, as the majority are developing new crowns of leaves. *Dion edule*, of which there are some grand examples, is particularly fine this season, a remark which also applies to the majestic heads of the less rare *Encephalartos Altensteini*, *E. Caffer*, and its variety *semi-dentatus*, which is producing several cones. The glaucous foliage of *E. horridus* and *E. Lehmanni* contrasts finely with the deep green leaves of *Cycas revoluta* and *C. circinalis*, which are also unusually attractive. The new *E. Friderici Guilielmi* is a highly ornamental species; the long comb-like leaves, being of a slightly glaucous hue, have a fine effect. A nearly allied kind, if not identical, is *E. mexicanus*, which is also named in some collections *E. Williamsi*. The *Macrozamia* from Queensland, and the *Ceratozamia* from Mexico, too, are very elegant, and though not specially noteworthy, are at present highly interesting.

Double-flowered Potentillas.—We have received from Mr. Stevens' garden at Byfleet some examples of these showy hardy plants, which are finer than we have ever before seen them. Some of them measure fully 2 in. in diameter. They vary in colour from a deep rich crimson to a clear yellow, and in some flowers both colours are combined. They seem to be crosses between *P. atrosanguinea* and *P. insignis*, both Himalayan species with wrinkled, trifoliate leaves, which are covered with silvery down on the under surfaces.

New Variety of Iris Douglasi.—A distinct and well-marked form of this fine Californian Iris is now in flower in the Kew collection. Its foliage is more erect than that of the type, without the conspicuous ribs on the surfaces and the reddish tinge at the bases of the leaves. The flowers are of a creamy-white, delicately pencilled with mauve, and have a blot of orange colour on the claws. This variety was collected at Santa Cruz, California, and though not so showy as many kinds is well worth including in every collection of Irises.

Hunnemannia fumarisæfolia.—We met with a good specimen of this handsome Mexican plant at Oakfield the other day. It is an erect-growing perennial from 2 ft. to 3 ft. high, with glaucous leaves, which, as its specific name implies, resemble those of some of the Fumitories. Its flowers are large and showy, of a rich orange colour, and in form resemble those of the well-known *Eschscholtzia californica*, but superior to them, inasmuch as they continue in perfection for a considerably longer period.

Cypripedium trapeanum.—A considerable number of this rare Mexican Orchid was offered for sale at Stevens' this week, and as it seems it can now be imported successfully, we hope to see it more widely cultivated, as it is one of the finest of greenhouse Lady's Slippers. The flowers, which are showy, have an unusually large, bright yellow, pouch-like lip, and as many as seven blossoms are produced on each stem. Some of our most skilful cultivators are, we find, now turning their attention to this interesting class of Orchids.

Calliandra tereginata.—This is now one of the most attractive plants in the Palm-house at Kew. It is a West Indian shrub about 6 ft. high, with a flattish head, which is studded profusely with tassel-like clusters of flowers, the stamens of which are long and whitish and the tips of a reddish brown. The leaves consist of about three pairs of leaflets, which give the plants a light and elegant appearance.

Nigritella suaveolens and N. coccinea.—These two Alpine Orchises are now very beautifully in flower in the York Nurseries. The colour of the former is a light soft rose, and its flowers are deliciously fragrant; that of the latter is bright scarlet. They thrive well when planted in well-drained sandy peat.—R. P.

Royal Horticultural Society.—Arrangements have been made for holding an evening *fête* in the gardens at South Kensington on Wednesday next. Upon this occasion various systems of electric lighting will be displayed. The conservatory and the flower show tents will also be brilliantly illuminated. As the members of the International Telegraph Conference, now being held in London, will

be present, every effort is being made to render this occasion one of the completest exhibitions of open-air electric lighting ever seen. The whole of the arcades, quadrants, and exhibition tents will be connected and lighted, so that in the event of wet weather it will be possible to walk entirely round the gardens under cover.

Calochortus Benthami.—This rare and pretty species we saw a few days ago in flower at Kew. In size and form of blossoms it is similar to *C. elegans*, but the colour of the flowers is deep rich yellow, and the inside and margins of the sepals are covered with short, dense hairs of the same colour. It is a native of California whence it has been lately imported successfully in quantity.

Melons.—We have received from Mr. Gilbert, of Burghley, a fine fruit of his *Netted Victory*, a white-fleshed Melon of the very finest flavour, even this year when Melons, as a rule, are not remarkable in that respect. It is nearly related to his *Victory* of Bath, also a very fine Melon, and one to which many prizes have been awarded. *Netted Victory* has also more than once been certificated.

Hardy Rose-coloured Lily.—Messrs. Fraebel & Co. have sent us a photograph representing this beautiful variety of the common white Water Lily (*Nymphaea alba*) growing luxuriantly and flowering abundantly in a large tank in their nurseries at Zurich. This Lily promises to bloom freely this year at Kew, and we hope soon to see it adorning our ornamental waters everywhere.

Oncidium macranthum var. hastiferum.—A fine variety of this large-flowered *Oncidium* is now in flower in Mr. Bull's nursery at Chelsea. It is furnished with from forty to fifty blooms, each about 3 in. across, with pale olive-yellow sepals, bright yellow roundish petals, and a brownish-crimson hastate lip surmounted by a white crest. The flower-spike measure from 5 ft. to 9 ft. long; it is, like the type, a native of Ecuador.

Tuberous-rooted Begonias at Chelsea.—Messrs. Veitch & Sons still continue to produce improved varieties of this popular family of plants, the most recent results being remarkable not so much for the large size of the blossoms as for the rich and uncommon colours which they possess, varying, as they do, from the most intense scarlet to a pale rose. One variety in particular is very beautiful, its flowers being of fine form and of a pleasing cherry-rose tint. An extensive collection of the older varieties is also in full beauty and well worth a visit.

Primula capitata.—The flowers of this beautiful Himalayan Primrose assume a variety of shades in cultivation, and by far the finest form of it with which we have yet met is now in full beauty on one of the rockeries at Kew. Its blossoms, which are of a deep rich purple, are of large size, and contrast admirably with the white mealy substance with which the flowers are enveloped. It would be interesting to know if these fine varieties can be perpetuated by means of seed or by off-shoots only, which would, we imagine, be rather a slow process.

Hæmanthus Kalbreyeri.—The brilliant effect which this showy bulbous plant produces when grouped in large numbers is unsurpassed by any other plant with which we are acquainted. The number of flowers borne on each stem is very remarkable, and as they develop in quick succession, thus supplying the places of those that die off, the length of time the plants last in flower is accounted for. Such a sight as that which we saw a day or two ago in Mr. Bull's nursery at Chelsea, where hundreds of plants of this *Hæmanthus* are now masses of dazzling scarlet, is not often seen.

Orchids at Chelsea.—The Orchid houses in Messrs. Veitch & Sons' nursery are still gay with *Odontoglossums*, *Masdevallias*, and *Oncidiums*, including a fine example of the beautiful *O. Lanecanum* and various species of *Lælias* and *Cattleyas*. The most conspicuous feature, however, is the fine display of East Indian kinds, consisting of a large number of *Aerides odoratum* with its numerous varieties; also *A. virens*, *A. maculosum*, *A. Larpentæ*, *A. Lobbi*, and the rare *A. Schröderi*, all in vigorous health and bearing hundreds of flower-spikes, the aromatic perfume from which is delicious. The length of time during which these Orchids continue in perfection, both in a cut state and on the plants, much enhances their value for decorative purposes, for they have been in flower already a week or so, and will produce a succession of blossoms for several weeks to come.

Special Prizes.—We are requested to state that the prizes offered for competition in "Class G" at the next meeting of the Royal Horticultural Society will be for twelve sorts of vegetables instead of thirteen, omitting *Globe Artichokes*, which will not be ready generally at that date.

We learn that Mr. F. W. Moore, eldest son of the late Dr. Moore, has been appointed curator of the Botanic Gardens, Glasnevin, an appointment which we are sure will give universal satisfaction. Mr. Moore has been for some time curator of the College Botanic Garden, Dublin. We believe that all who know Glasnevin will feel that the best thing has been done in this case.

Messrs. Carter's Annuals.—The exhibition of these, now being held in the Royal Botanic Gardens, Regent's Park, is well worth a visit, though, owing to the late unfavourable state of the weather, it will yet be in better condition. It comprises all the most popular annual border flowers, together with many that are as yet little known, but which as shown cannot fail to be appreciated. Amongst the older types the different strains of *Gilias*, *Phloxes*, *Nemophilas*, &c., are particularly rich as regards variety of colour. The arrangement of the whole collection is, we consider, an improvement on that of former years.

NOTES ON HARDY PLANTS IN FLOWER.

Kew.—The present season has been highly favourable, in the light soil here, for the growth of the hardy plant collection, though there is yet a comparative dearth of bloom. Amongst bulbous plants *Allium cœruleum* and *A. MacNabianum* are worthy of note, especially the former, the deep blue globular heads of flowers of which are such an uncommon occurrence. *A. atropurpureum* has the deepest red flowers of any, though not such an ornamental plant as *A. MacNabianum*. The white-flowered Bearded Harebell (*Campanula barbata alba*) is a pretty plant well worth growing, as is also the type. Pentstemons are showy just now, and, in addition to those previously alluded to, we noticed *P. Wrightii* and other choice kinds. Amongst Irises the original type of Kämpfer's Iris is very beautiful, though inferior in form to some of the varieties that have sprung from it. The Portuguese Iris (*Niphon lusitanicum*) is the best of the yellow-flowered kinds, its rich colour being very attractive. The Japanese variety of *I. sibirica* is much superior to the type; it resembles *I. sanguinea* in size, but it is a shade or two lighter in colour. *Dianthus dentosus*, one of the prettiest of Pinks, has flowers of a bluish-purple colour about the size of a florin and toothed at the edges. It is very dwarf and produces flowers in abundance. Amongst Alpines the rarest in flower are *Edraianthus pumiliorum* and *E. caricinum*; they are, however, scarcely in a condition to comment on their merits. *Anthemis Aizoon*, an interesting Composite with narrow, hoary leaves arranged in a rosette-like tuft, is producing white flower-heads $\frac{3}{4}$ in. across. The Edelweiss is growing here in an ordinary border larger than we have yet seen it, the flower-heads being nearly 3 in. across; but its leaves are almost devoid of the characteristic white down with which specimens grown in high Alpine regions are furnished.

Wimbledon Park.—The garden of G. Joad, Esq., at Oakfield, so richly stocked with hardy plants, is now highly interesting, the majority of them being in flower. Not only does the collection represent plants in general cultivation, but it also contains many that are probably not in cultivation elsewhere in this country, a remark which applies more particularly to rare European plants, to which Mr. Joad pays especial attention. Various methods are resorted to here in order to ensure successful treatment of hardy plants, for, besides the extensive rockeries and beds out-of-doors, there is a capably constructed rockery under glass and spacious houses for the tender kinds and those little known and of doubtful hardiness. Amongst the rarer of the Alpine plants we noted the pretty dwarf *Androsace Wulfeniana*, from the Styrian Alps, a plant which grows in dense rigid tufts about 2 in. high, and which are studded with vivid rosy blossoms. *A. glacialis* is another compact-growing species, but the flowers in this case are smaller and of a paler hue than those of *A. Wulfeniana*. The Himalayan *A. lanuginosa*, too, is well established in a deep crevice of the porous tufa, with which the rockery is constructed, and so placed that its long slender branches of silky leaves hang over a dry ledge, an indispensable condition as regards its successful culture. Another Himalayan gem of rare beauty is the Hoary-leaved *Cyananthus* (*C. incanus*). Though reputed to be difficult to cultivate, it succeeds admirably with Mr. Joad planted on the indoor rockery, where it is now covered with pretty violet-purple flowers. The Mont Cenis Harebell, though perhaps not so showy as many others, is nevertheless an extremely rare and interesting species. It grows but 1 in. or 2 in. high, is tufted in habit, and produces small funnel-shaped blossoms singly on slender stalks. Here we met with the singular *Lewisia rediviva* in flower. Its blossoms measure about 2 in. across, are of a bright rose tint, and are surrounded by a few fleshy erect leaves. It is so dwarf that the flowers appear to be lying flat on the soil. Fine examples of *Campanula fragilis*, with its branches covered with blossoms, hang over the ledges of the rocks, and when seen in such a thriving condition it is one of the prettiest of the Harebells. One of the finest of the Silences is undoubtedly *S. virginica*, which we saw here in full beauty. Its flowers are as brilliant as those of a scarlet *Pelargonium*, and the petals are beautifully fringed. The little Grass-leaved *Lithospermum* (*L. petraeum*) is thriving here better than we have hitherto seen it,

and produces its pretty deep blue flowers in profusion. It requires apparently a dry position during winter in order to grow it successfully. The *Pelargonium*-flowered *Erodium* (*E. pelargoniflorum*), succeeds well in this house and flowers very freely. It is somewhat straggling in habit, but its blossoms are very pretty, being pure white with two conspicuous purple-black blotches on the upper petals, from which radiate faint pencillings. The charming little *Erpetium reniforme* is quite at home in one of the nooks in the rocks, and is covered with its pretty Violet-like blossoms. Various kinds of *Isia*, *Babiana*, *Sparaxis*, &c., succeed admirably here, and enliven the surroundings with their gay spikes of blossoms. Such plants as *Veronica taurica*, *Erodium macradenum*, *Gazania ringens*, and a host of other Alpines of the commoner type may be seen in masses, and are now covered with flowers. The Nepalese Poppy (*Meconopsis nepalensis*), too, is a noble occupant of this house; also the showy *Lilium tenuifolium* and *Calochortus splendens*. In outside borders, amongst a host of plants in flower, we noted a fine example of one of the Rocky Mountain Pentstemons with long dense racemes of clear cerulean-blue flowers. Most of the *Geraniums* are in flower, including the handsome *G. armenum*, one of the best of the large-growing kinds, and the pretty *G. subcaulescens* with its rosy blossoms, with a deep purple centre, is also the most desirable of the dwarf species, together with its near ally, *G. cinereum*, which is similar in growth and habit, but with the black spot in the blossoms. *Helenium Hooperi* is one of the showiest of the Composite family at present in flower, the rich orange flower-heads being highly attractive. The same remarks apply to *Senecio Doronicum*, which is amongst the finest of the Groundsels, as it is of dwarf growth with flowers of a similar colour, but smaller in size. *S. abrotanifolius* is not often met with in flower, but here we saw it in fine condition, producing several of its bright orange-coloured flower-heads. *Arnica montana* is another good Composite and well worth growing. It is yet too early for most of the Larkspurs, though the Cashmere species (*Delphinium cashmerianum*) has for some time been in flower, and a very desirable plant it is, as it is dwarf and flowers in profusion. The Caucasian Primrose (*Primula luteola*) we saw here finer than we have yet met with it; the plants are growing under the shade of a wall, which seems to suit it admirably. The Sikkim Primrose (*P. sikkimensis*) growing in the same spot was also remarkably fine. *Cynoglossum montanum* is one of the best of the Borage-worts, and makes a showy object for some time, and quite as rich in colour as *Mertensia virginica*, which is so much esteemed. The Pea family was numerous represented, the most noticeable being the Iberian *Coronilla* (*C. iberica*), which is now gay with its large heads of bright yellow blossoms hanging over the ledges of the rockwork. Another desirable dwarf plant is *Astragalus vaginatus*, which produces its rich deep purple flower-heads abundantly. *Orobus canescens* is one of the most useful plants of its kind and very showy, and keeps in perfection for a long time. The Harebells thrive capably in this garden, judging by the large plants of the white *Campanula nobilis alba*, *C. barbata*, *C. eximia*, *C. turbinata*, and others; the last-named species is without doubt one of the finest of all the dwarf kinds, and quite unsurpassed by any of the newer species. Various kinds of terrestrial hardy and half-hardy Orchids Mr. Joad grows very successfully. Those now in flower comprise the rare *Satyrium aureum*, the pretty *Orchis laxiflora*, and others less rare. The rarer of the Alpines in flower on the open rockeries include the neat-growing *Trifolium uniflorum*, which is so seldom met with; *Linaria origanifolia*, one of the prettiest of all the species; *Armeria juncea*, figured in THE GARDEN (Vol. XIV., plate 146); *Achillea Clavennæ*, *Anthemis Aizoon*, and *Anthyllis erinacea*, a singular dwarf shrub covered with spines and producing small purplish flowers abundantly. *Gypsophila cerastioides* is also a charming little plant, quite distinct from its large-growing and straggling congeners, and should adorn every rockery. Of the rare European plants, *Saussurea discolor* (a dwarf species with bluish flowers), *Chamaepuce gnaphaloides* (a species with no prickles on the leaves), *Achillea macrophylla*, and others were particularly noteworthy.

Bromsgrove.—The rockeries here have been and are beautiful in spite of the constant heavy rains. Iberises have been unusually prolific of bloom; also *Phlox frondosa* and *subulata*; *Saxifraga pyramidalis* bears dozens of delicately-branched candelabra; *Linum narbonense* has survived the winter in most cases and is blooming well, and *Aquilegia cœrulea* has never done so well, although quite unprotected through the long winter and tardy spring. I have succeeded in raising and blooming *Aquilegia grata* from seed, supplied by Mr. Thompson, of Ipswich. It is a little gem; unfortunately its delicate blooms have been sadly splashed by the mud surge which the late rains have raised. Bedding plants are late and unsatisfactory, but we had no difficulty in raising an ample stock of *Mentha Pulegium* which many people seem to have lost. I have seen some *Viola* blooms raised by Messrs. Dickson, of Edinburgh, which will cause genuine delight and surprise when sent out. Two in particular

I noted of different shades of blue, large in size, perfect in shape, and thick in substance. It would really seem impossible to improve on these lovely flowers. Has any one grown *Viola picturata*? It is a little gem. I should like to try it with pink Daisies; the harmony would be charming.—H. M.

Kirkstall.—Just now the best blooming plants on my rockeries are the *Helianthemums*, such as *Royalty*, *Rosy Gem*, *Purity*, *Orange Perfection*, and *vulgare*. *Silene alpestris* has snow-white flowers of good substance, and they do not suffer as those of most plants now do from heavy rain; *Lychnis chalcidonica* fl.-pl. is very showy; *Aquilegia chrysantha*, in a moist position, has increased in size very much, and is just beginning to bloom freely; *Dianthus* are doing well; *D. alpinus* and *D. neglectus* are now both in bloom; patches of *Veronica rupestris* are sheets of rich dark blue; *V. verbenacea*, too, is now at its best. No rockery should be without these two *Veronicas*; they are always to be depended upon; they are vigorous, and produce abundance of flowers of an unusual shade of colour. All my *Campanulas* have made a good deal of growth, and are now beginning to flower freely. A few of the hardy *Geraniums*, too, are dense bushes of healthy foliage, dotted with rather frail blooms. Of *Aster alpinus* with its antique-coloured flowers, we have good clumps which are very effective.—JOHN WOOD.

Tottenham.—The quaint-looking *Iris susiana* is now finely in flower on the rockery in Mr. Ware's nursery; it apparently thrives best when planted on elevated, well-drained spots. Its sombre-tinted flowers are quite unlike those of any other hardy plant. Amongst hardy *Cypripediums* the rare little *C. candidum* is flowering freely; its blossoms are a trifle smaller than those of *C. parviflorum*; the sepals are of the same colour as those of that kind, but the lip is about 1 in. long and egg-shaped, pure white, and shining. Amongst *Calochorti* we noticed *C. elegans* and its large-flowered varieties *Nuttalli* and *Maweanus*; also the beautiful yellow *C. pulchellus*. It is yet too early for *Lilies*, but *Lilium tenuifolium*, one of the most graceful and pretty kinds, is already producing its scarlet, turban-shaped blossoms. *Moræa pavonia*, a pretty Cape bulbous plant, has flowers from 1½ in. to 2 in. across, pure white with deep blue spots at the angles of the corolla. The white-flowered form of *Lychnis Lagasæ* is very pretty, and it is quite as free flowering as the original kind. The double-flowered *Geum coccineum* is certainly one of the most useful of hardy plants; its blossoms are as double as those of a *Pelargonium*, and they last considerably longer in perfection.

Tring.—I send you flowers of two plants which are now conspicuous for their delicate beauty in my garden at Drayton-Beauchamp, Tring. The sprays of small white flowers are those of *Cotoneaster nummulariæfolia*, which I have trained into a standard some 8 ft. high; the branches spread and weep in a most graceful manner, and are perfectly smothered with bunches of little pure white blooms. The *Vetch* I received in seed some five years ago from the Continent as *Vicia armena*. It has flowered every summer but never with such healthful and elegant luxuriance as at the present time. It appears to be impatient of heat and drought, and the late moist and sunless spring seems to have suited it exactly. According to Boissier's "Flora Orientalis," Vol. II., p. 583, *Vicia armena* = *V. persica* var. *stenophylla*, and is a native of Mount Ssahend, near Aderbidjon, in Armenia. It is a plant which ought to be in every garden, but it is not easy to propagate. It has not at present ripened seed with me.—H. HARPUR CREWE.

EFFECTS OF THE WINTER.

THE following is the condition of the more tender plants and shrubs in South Derbyshire after the late exceptionally severe and prolonged winter:—

KILLED.—*Chamærops Fortunei*, *Agave americana*, *Myrtle*, *Sweet Verbena* (*Aloysia citriodora*), *Passiflora cœrulea*, *Gum Cistus* (two plants), *Mesembryanthemums*, *Echeveria secunda*, *Crinum Moorei*, *Begonia Vetchi*, *B. Frœbeli*, *B. Pearcei*, *Convolvulus Cœneum*, *Aquilegia cœrulea*, *Bravoia geminiflora*, *Iris alata*, *I. tingitana*, *I. caucasiæ*, *Lilium Kramerii*, *Fritillaria oranensis*, *F. recurva*, *Tritoma grandis*, *Commelina cœlestis*, *C. c. var. alba*, *Wallflowers*, single and double (all but four plants).

INJURED VERY SEVERELY.—*Bay*, *Arbutus*, *Aucuba japonica*.

INJURED, BUT RECOVERING RAPIDLY.—*Common Laurel*, *Magnolia grandiflora*, *Berberis Darwini*, *Gum Cistus* (one plant), *Escallonia macrantha*, *Tritoma Uvaria*, *Pampas Grass*, *Helleborus lividus*, *Gunnera scabra*, *Schizostylis coccinea*, *Iris stylosa*, *Laurustinus*.

ESCAPED UNINJURED (having been protected with matting or fern litter).—*Camellia*, *Chamærops excelsa*, *Amaryllis Ackermanni*, *A. vittata rubra*, *Lilium giganteum*, *L. auratum*, *L. Thomsonianum*, *Scilla maritima*.

ESCAPED UNINJURED (without any protection).—*Araucaria imbricata*, *Abies Douglasi*, *Cedrus Deodara*, *Wellingtonias*, *Euonymus japonicus*, *E. variegatus aureus*, *Bignonia radicans*, *Hydrangeas*, *Tropeolum speciosum*, *Tricyrtis hirta*, *Agapanthus umbellatus*, *Lilium speciosum*, *L. monadelphum*, *L. pardalinum*, *L. eximium*, *Hyacinthus candicans*, *Gladiolus gandavensis*, *G. Colvilli*, *Watsonias*, *Iris Kämpferi*, *I. Histrio*, *I. reticulata*, *Orehis foliosa*, *Primula cortusoides*, *Rose Maréchal Niel* (on south wall), *Parlanthus chinensis*, *Tritonia aurea*, *Anomatheca eruenta*, *Babianas*, *Zephyranthes candida*, *Pancretium illyricum*, *P. maritimum*, *Libertia pulchella*, *L. azurea*, *Narcissus Tazetta* (several varieties), *N. triandrus*, *N. Bulboodium*, *N. Græsi*, *Chionodoxa Forbesi*, *Tulipa persica*, *T. Greigi*, *T. Kolpakowskiana*, *T. Haageri*, *T. celsiana*, *Brodiaea coccinea*, *B. congesta*, *Trielcia laxa*, *Crinum capense*, *Sternbergia lutea*, *Dicentra spectabilis*, *Plumbago Larpenæ*, *Clematides*, *Myosotis dissitiflora*, *Papaver alpinum*, *Fritillaria persica*.

Roses of all kinds have suffered severely, and the losses are too numerous to mention.

HUGO HARPUR CREWE.

Calke Abbey, Derby.

CATALOGUE OF CALIFORNIAN FERNS.

POLYPODIUM (Polypody).—*Vulgare* (L.), northern; *Scouleri* (H. & G.), central, rare; *californicum* (Kaulf.), common. There are several other species credited to California. I think a careful study of the genus as it occurs in our State would reduce the number of species to one or two. *P. californicum* is exceedingly variable, according to the place in which it grows. Its different forms have led to a variety of names, such as *intermedium falcatum*, *occidentale*, &c.; but there does not seem to be need for so many species. And it is possible that *P. vulgare*, which is credited to northern California and Oregon, may include all the rest.

GYMNOGRAMME (Gold and Silver Fern).—*Triangularis* (Kaulf.), common. A beautiful plant with deep green leaves on the upper side, and silver or golden-dusted underneath, according to age.

NOTIOLENA (Cloak Fern).—*Candida* (Hooker), southern; *Parryi* (Eaton), southern; *Newberryi* (Eaton), southern. These beautiful little Ferns are not found much north of San Diego. The *N. Newberryi* is a beautiful velvety Fern of uncommon attraction. *N. candida* has a fine coloured powder, somewhat like that of our *Gymnogramme*.

CHEILANTHES (Lip Fern).—*Californica* (Mett.), "Lace Fern." *Santa Barbara*, San Diego, Santa Cruz, Yosemite, and north to Butte County, somewhat rare, rocky crevices; *viscida* (Davenport), south-eastern to Downieville, discovered by Lemmon and Parry; *Cooperæ* (Eaton), southern, Santa Barbara; *gracillima* (Eaton), northern; *Fendleri* (Hooker), from Mt. Diablo, south; *Clevelandi* (Eaton), southern; *myriophylla* (Desv.), Lake County to San Diego. A beautiful genus, most abundant in dry and barren regions, among rocks.

CRYPTOGRAMME (Allosorus of some authors).—*Acrostichoides* (R. Brown), western side of the Sierras, from northern to southern.

PELLÆA (Cliff Brake).—*Breweri* (Eaton), high Sierras, Hope Valley; *Bridgesi* (Hooker), high Sierras; *Wrightiana* (Hooker), high central Sierras to San Diego; *ornithopus* (Hooker), common on sandy hillsides, central; *brachyptera* (Baker), northern Sierras; *andromedæfolia* (Fee), common from Santa Cruz south; *densa* (Hooker), Yosemite and in Sierras, north and south. A very pretty genus of Ferns, easily cultivated, and improved as house plants or outdoors.

PTERIS (Common Brake).—*Aquilina* (L.), found everywhere around the globe. Ours is a variety called *lanuginosa*, and only differs from the type in having a kind of woolly hair growing on the fronds.

ADIANTUM (Maidenhair).—*Pedatum* (L.), moist shaded cliffs of streams throughout the State, as well as United States; *marginatum* (Hooker), similar localities, but more general. This is the *A. chilense*, central and southern; *tricholepis* (Fee.), said to be found by Nuttall at Monterey—I have never seen it; *Capillus-Veneris* (L.), southern.

LOMARIA (Jointed Pod Fern).—*Spicant* (Desv.), from Santa Cruz to Oregon, deep ravines in mountains, rare below central California. The fruiting fronds resemble slender Bean pods.

WOODWARDIA (Chain Fern).—*Radicans* var. *americana* (Hooker), from Santa Cruz Mountains to Santa Barbara, also north in Yuba County. One of our largest and most showy Ferns; in the mountains about springs.

ASPLENIUM (Spleenwort).—*Trichomanes* (L.), var. *incisum* (Moore), San Diego; *Filix-fœmina* (Bernh.), common along beds of mountain streams throughout the State; var. *rhaeticum* (Moore), found by Miss Pelton, 1877; locality not given.

PLECOPTERIS (Beech Fern).—*Polyodioides* (Fee.), said to exist in northern California; *alpestris* (Mett.), highest Sierras; found by Miller and Lemmon.

ASPIDIUM (Shield or Wood Fern).—*Munitum* (Kaulf), central and northern; the varieties *nudatum* and *imbricans* (Eaton) are found in the Sierras; *aculeatum* (Swartz), in Santa Cruz Mountains, one form of this has been known as *A. californicum*; *nevadense* (Eaton), Sierras; *patens* (Swartz), Santa Barbara; *argutum* (Kaulf), central and southern, perhaps north.

CYSTOPTERIS (Bladder Fern).—*Fragilis* (Bernh.), throughout California, including the variety *dentata* (Hooker), extremely variable.

WOODSIA.—*Scopulina* (Eaton), found by John Muir, probably in the Sierras.

BOTRYCHIUM (Moonwort).—*Simplex* (Hitch.), Yosemite; *ternatum* (Swartz), northern Sierras; *virginianum* (Swartz), locality not given.

There are sixteen genera and forty-three species of Ferns in California, and further discoveries will doubtless increase the number; while it is likely some few species mentioned may not hold good, but come within other specific limits.—*California Horticulturist*.

THE KITCHEN GARDEN.

Asparagus.—The writer on Asparagus (Vol. XV., p. 467) must have been singularly unfortunate in the samples of green which he has tasted to be able to compare them adversely with the blanched heads that appear to have given him so much satisfaction, or else he must have a different taste from that of most people who know what good Asparagus is. If white Asparagus is so much superior to the green, how comes it that in private gardens where the best of everything is produced there is no demand for it, and it is only in cities and towns where people hardly know what it is to have good fresh vegetables blanched Asparagus is tolerated. That the green may deteriorate by exposure and become bitter I can readily understand, and it is just possible that the white having nothing to lose in flavour may be improved thereby. I see it is remarked in a late number of THE GARDEN that the best French Asparagus has pinkish points, which clearly shows that that slight particle of colour is an improvement on the blanched, and it is only reasonable to suppose that an extratinge would improve it still further. In the same paper it is also admitted that the best English has a shade of green on the top, which is the very thing I have all along stated, and I contend that the more there is of it the better it is. The subject is an important one and is worthy of free and full discussion, for if there is any advantage to be derived by heaping soil on the beds to prevent Asparagus being exposed to the light, by all means let us resort to the practice. In blanched Asparagus what can there be but crude, unconverted sap? and if whiteness had anything to do with improving it, why then the Belgian and Dutch ought to be the best, as it appears that what they grow and send is whiter than any.—S. D.

Seakale for Forcing.—As far as my experience goes I agree with "J. S. W." (p. 520) that there is no occasion to have two-year-old plants for forcing if anything like good cultivation be given to seedlings the first year. Last winter I forced a quantity of plants and cut the produce within nine months of the date at which the seed was sown, and it was quite equal to that from purchased plants, which, although apparently much stronger, are as a rule most ruthlessly broken in lifting. At the same time I prefer raising part of my stock from sets or pieces of roots for the earliest forcing, and reserve seedling beds for a late supply, as even weakly-looking crowns if left in the ground and blanched will furnish very serviceable dishes for late use. We all know how tenacious of life Seakale is, but at the same time the more the roots are broken off in removal the less size and weight there must be in the produce. A season like the present is greatly in favour of sets, as seeds of all kinds start slowly, and when they do start they get badly injured by slugs, while pieces of roots wintered in sand and planted in rows 2 ft. apart are now making fine plants. Seedlings, if sown in good soil early and thinned out so as to have plenty of room in which to develop their leaves, will astonish those who have hitherto only sown thickly in seed beds.—J. GROOM, *Linton Park, Maidstone*.

Culture and Uses of Tomatoes.—In growing Tomatoes out-of-doors in a climate like that of England, the nearer you can grow them to the ground, keeping them free from the splash of the rain, and the greater surface of plant you can expose, not simply to the sun, but also to the heat radiated from the earth's surface, the better. In India I used to grow them extensively on a horizontal framework of Bamboos, tied to stakes about 18 in. from the ground. I have done the same in England, using some old sheep hurdles resting on blocks about 9 in. high; the Tomato spreads over the bar of the hurdle and ripens better than even when trained to the wires of a south wall. This hint, if new, may be of use to Tomato growers. The ripe Tomato, as a rule, is used by Englishmen only as sauce or in soup; split into two, and fried with bread crumbs it is delicious; sliced raw with Onions and dressed with oil and vinegar, it makes

the tastiest salad possible; and covered with strong vinegar and kept in jars, it can be preserved for months, ready when required to do duty as a salad. But it is not only the ripe Tomato that is of use. The large quantities of green Tomatoes that are thrown away late in the autumn, not being sufficiently advanced to ripen of themselves, can be converted into the most luscious jams or tasty pickles. The green Tomato forms the best vehicle for either sugar as a preserve or vinegar as a pickle of any vegetable substance grown.—A. T. P.

Keeping Asparagus Fresh.—The following plan of preserving Asparagus fresh for several days may be of service to your readers. We never allow the heads to more than break through the ground, and the beds are looked over three times a day. In order to keep the heads fresh we have holes dug in a shady situation, and here we lay those that are not required for the day's consumption, covering them lightly with mould, and placing a tile over the hole to exclude rain. In this way the delicate flavour of the Asparagus is entirely preserved. I may add that our cook peels every stick of Asparagus before boiling, and it is a rare case in which any is not eatable to the very end.—CONSTANT READER.

Birds and Seeds.—Finches I find to be the most destructive seed eaters; even nets, sometimes, no matter how well secured, fail to keep them out. Where one sows perhaps a dozen or a score of different sorts of Broccoli and other winter greens, to dress them with red lead and keep each kind separate is a tedious operation; but for Turnips, Radishes, and Peas, the matter is very simple, and involves no trouble or expense worth mentioning. It is only necessary to put the seeds we intend sowing in a basin or some other vessel, scatter a little lead over them, add a very small quantity of water, and mix the whole together till each seed has taken on a coat of red. If this was more regularly attended to there would not be so many complaints of loss of crops from the depredations of birds and mice.—E. HOBDAV.

Rosette Colewort.—In a good many private gardens Coleworts are not much grown. Where it is the custom to allow the Cabbage stems, from which the spring and summer Cabbages have been cut, to remain for a second crop, there is generally plenty of young, tender hearts equal to Coleworts without making a special sowing or planting. But often during severe winters, as was the case in many gardens last winter, the old Cabbages were destroyed whilst the young Coleworts remained uninjured, proving that it is hardly wise to depend upon one source of supply. If the Rosette Coleworts be sown now thinly in drills they will be fit to transplant about the end of next month, and may be planted as a catch crop to fill up vacancies anywhere, giving each plant about a square foot to grow in.—E. HOBDAV.

VEGETABLE CULTURE FOR MARKET.

ONIONS.—For good Onions there is always a large demand, and late in the season they fetch high prices. In nearly all market gardens round London Onions are grown to a large extent both as summer and winter crops. In the neighbourhood of Lea Bridge large fields are devoted to them, and from this district come large quantities of the finest produce brought to market. Great breadths of Onions are also grown at Fulham, Chiswick, Deptford, and Mitcham, the land thereabouts being light and rich and well suited for their culture. The main spring sowing, which consists usually of the Deptford and Reading varieties, is made as soon after the middle of February as the condition of the soil and weather permits. If the seed be good and is sown broadcast, 9 lb. to 12 lb. per acre is used, but if sown in lines only 8 lb. to the acre is needed. Land intended for Onions is generally roughly trenched during winter and thrown into ridges, so as to become thoroughly pulverised and sweetened by the action of frost. During dry weather in February the ridges are levelled and the surface rendered smooth by raking and rolling, after which the seed is sown either broadcast or in drills 9 in. to 10 in. apart. If small pickling bulbs be desired, seed is sown broadcast at the rate of 20 lb. per acre. After sowing, the seed is raked or harrowed in, and the operation is completed by rolling the surface firm and even. After the young Onions appear above the ground, weeding and thinning are proceeded with as may be required. The varieties generally selected by growers for

market are the Reading or White Spanish, Deptford, Brown Spanish, and James' Keeping. The Silver-skin, for pickling, and the White Spanish, Lisbon, and Tripoli varieties are sown in August to produce young salad Onions for winter and bulbs for spring use. The Deptford variety is one of the best sorts, producing heavy, firm bulbs, which keep well through the winter months. Broadcast sowing is considered the best for spring-sown crops, as involving less labour; and as the bulbs, after thinning, stand at regular distances apart over the whole area, the produce per acre is considerably more than when sown in beds or lines. Seed sown in the autumn is, however, sometimes drilled on beds 4 ft. or 5 ft. wide, these being divided by narrow alleys which serve as walks for labourers who weed the beds and draw the crop as required for market, but this crop is also often sown broadcast.

Onion seed takes a long time to germinate, but if the ground be clean and well tilled, weeds will not appear much sooner than the Onions, or, at least, not so thickly as to choke them. As soon as the Onions have fairly come up, women or men accustomed to Onion cleaning are set to work amongst them. These operators are furnished with the short-handled 2½-in.-wide hoes, with which they hoe down the weeds and thin the whole crop with wonderful certainty and expedition. The field is marked off into strips for the guidance of the hoers, to each one of whom there is a space of 6 ft. given, so that were four cleaners employed the strips would each be 24 ft. wide. People accustomed to this work do not trample carelessly about; nor, indeed, can the crop be materially damaged by doing so, for the Onions that are thus prostrate to-day are nearly erect to-morrow. Each plantation is generally cleaned by this means three times during the season, the last cleaning being made about the end of June or early in July, and any large weeds that appear after that time are pulled out by the hand. Towards the end of August or early in September the Onions, being ripe, are harvested when dry. Those that are green and thick-necked are laid aside for immediate sale; but the firm and sound bulbs, particularly of the Deptford kind, are either cleaned of any loose scaly skins and spread out a few inches deep over the floor of a loft, or tied into bunches and strung in pairs over poles or on pegs in a loft or shed, so that they can be marketed at any convenient season during winter and spring.

The profits on a good crop of spring-sown Onions are comparatively large, although the prices vary considerably in some seasons. Sometimes as much as £45 per acre is made of them by the grower, the purchaser being at the expense of harvesting the crop. At other times, however, £30 per acre is considered a good price. The silver-skinned Onion, which is grown largely for pickling, is sown on good land, the plants being left as thickly as they come up, as the closer they are together the sooner they will cease growing in summer and the better they will ripen their bulbs. Good clean bulbs realise from 8s. to 10s. per bushel in the market. The autumn sowing of Onions is made on ground cleared of Cauliflowers, Cabbages, or other early crops, in the end of July for drawing in a young state from September onwards, but the main sowing is not made till about the middle of August. The autumn sowings are, as a rule, made in beds about 5 ft. wide, and the seeds are covered deeper than those of the spring sowings. Autumn sowings of Onions are not often made broadcast on fields, as they must be weeded, not hoed, in the process of cleaning; the hoeing would thin them too much. As they are only required for drawing when young they do not need to be more than one-third of the distance asunder required in the case of the summer Onions. They are weeded soon after they come up, and once, or perhaps twice, during the winter time. Weeding is performed

by women in dry weather, each of whom takes a small round basket to put the weeds into rather than throw them on the alleys. In marketing these Onions they are cleared off the beds in large patches, and not by picking out the strongest and leaving the weakest, as is generally done, and they are washed, which makes them look white. If a portion be intended for transplanting, a piece of well-prepared rich ground is made ready for them, rolled firmly, and lined off into rows about 9 in. apart, and into these lines the young plants are dibbled about 6 in. apart. These make large saleable bulbs early in July. The kinds used for autumn sowings consist of White Spanish and White Tripoli or Lisbon. Some growers save large quantities of Onion seed, for which purpose well-formed bulbs are selected and planted in spring in rows which vary from 2 ft. to 6 ft. apart, Lettuce, Radishes, Spinach, or other low-growing vegetables being grown as intermediate crops. After the flower-stems make their appearance they are staked at intervals, and twine or cord is strained on either side the rows to prevent the stems being beaten down by hail, rain, or wind. Ordinary Onion seed fetches from 2s. to 5s. per lb., according to the season; but the best seed, or that from improved or rare sorts, is more valuable. In Hertfordshire large breadths of seed Onions may be seen in July, and on good deep land it is considered one of the most profitable of crops.

LEEKS.—These form a very remunerative crop to the grower for market who has good rich land and the means of supplying them with abundance of water. Large quantities of them are grown in the valley of the Thames where the soil is moist. The first sowing is made towards the end of January in a frame set on a gentle hotbed, on which has been placed a few inches of light, rich soil. The seed is sown rather thickly and afterwards slightly covered with fine soil. The sashes are then kept close until the young plants appear, when abundance of air is admitted both night and day on all favourable opportunities. If severe weather sets in the sashes are covered with litter or mats. On fine days plenty of water is supplied to the plants, and the soil is kept frequently stirred. If the seedlings are too thick they are thinned out to 1 in. or so apart, and those that remain are gradually hardened off until towards the end of March, when they are carefully lifted and planted out-of-doors in rows about 1 ft. apart, the plants in the row being about 6 in. asunder. Between the rows Lettuces are planted, and these, being of quick growth, are removed long before they can in any way injure the Leeks. The next sowing, which takes place about the end of February, is made out-of-doors in beds, and when large enough the plants are put out in a similar manner to the former sowing in heavily-manured, deeply-dug soil. Another sowing is made six or eight weeks later, and the last one generally about the first week in May. In all cases drills are drawn to a depth of 4 in. or 5 in., in which the plants are put. These in some measure protect the plants in the early stages of their growth and serve as receptacles for water. The frequent hoeing of the ground, which is considered a very important matter, fills in the drills and blanches the necks of the Leeks—one of the main things to be considered in their culture. During dry weather abundance of water is applied, and some growers, after taking a crop of Lettuce from between the rows, heavily mulch the ground with manure. The produce from the first sowing is ready for market by the beginning of August, when it is quickly removed and the vacant ground cropped with other vegetables. The latest sowing keeps up a constant supply of Leeks far into the winter when they are most in request, and when a bad Onion year occurs they pay remarkably well. When lifted for market the roots are left

entire, and, after being washed, the outside leaves are stripped off and the tops shortened; they are tied six or eight together in flat or fan-shaped bundles, packed in round hampers, and sent to market. Most growers save their own Leek seed, and for this purpose a quantity of the best plants are selected and transplanted to a sunny situation where they remain until the seed is ripe. When this is the case the heads are cut off, laid out to dry, shaken out of the husks, and stored in paper or canvas bags until wanted. The chief kind for early crops is the London Flag, but for main or late crops the Musselburgh is mostly preferred.

GARLIC AND SHALLOTS.—These are sparingly grown in market gardens, owing to their being used in small quantities for flavouring purposes rather than in quantity as substantial food. They are generally propagated by offsets from the old bulbs planted in rows in warm sunny positions in March, but if large quantities be cultivated, then seed gives the best results. Seed is sown broadcast or in drills 1 ft. apart in March or April, and the subsequent culture is similar to that of Onions. An acre of good land is said to produce upwards of 6 tons of Garlic from seed, and the wholesale value of this produce varies from £150 to £200. Garlic is one of the most wholesome of vegetables, but in England it is not used so extensively as in France and other Continental countries.

CHILIES AND CAPSICUMS.—These are grown in Cucumber houses or similar places where a brisk heat and plenty of moisture are maintained. The seeds are sown in pots in April, and when large enough the young plants are potted six or eight together in an 8-in. pot in good rich soil and placed on stages in a light position. Plenty of water is given them whilst growing. In August I have seen hundreds of pots full of plants in Mr. Wilmot's garden laden with ripe pods. Some plant them out in frames and in this way obtain abundance of fruit, but the most profitable way is pot culture.

ENDIVE.—This is largely grown in nearly all market gardens round London, and especially in those situated in moist districts. The first sowing is usually made early in May, either in frames or on prepared beds in the open air. In either case good rich soil is used in which to sow the seed, and the surface after sowing is made firm by being beaten with the back of the spade. The chief point in reference to early-sown Endive is to keep the plants continually growing, as if they experience the least check they run to seed or "bolt," as it is termed. On this account early Endive, as a rule, is not grown in very large quantities. The principal sowing is made early in June, and is succeeded by smaller ones to the end of July. In most cases the outdoor sowings are made on the ground on which they are to grow, as on Celery ridges or between the rows of any crops where there is room, and for which the ground was well manured. Sometimes, however, the seed is sown on beds and the seedlings thinned out if too thick and transplanted when sufficiently large to handle. In any case the distance apart of permanent plants is from 12 in. to 15 in. Endive and Lettuces are frequently planted on land alternately, large fields being often devoted to them; sometimes whole fields of Endive alone occur. Blanching is effected by tying the leaves like those of Lettuces with withies or pieces of bast. In from twelve to fifteen days after being tied up Endive is ready for market. The most forward piece is then cleared by pulling the plants up by their roots, and in this state they are packed in hampers and conveyed to market. The Dwarf Green Curled and the Batavian are the kinds chiefly grown, but the former sort is that which is grown in the greatest quantity. The produce from the earliest sowings is ready for market early in August and onwards until Christmas and even later. A few growers house plants for winter and spring supply, but

now, when they have to compete in the market with the French, the prices obtained scarcely remunerate them for their trouble and houseroom.

LETTUCES.—In cool moist soils Lettuces pay the grower much better than many other market crops, inasmuch as they are but a short time on the ground, and a large quantity can be grown in a comparatively small space; they frequently, indeed, fetch more money than Cabbages, which impoverish the ground more and remain on it for a much longer period. The best market Lettuces appear to be the Paris White Cos, Bath Brown Cos, and Grand Admiral Cabbage; and in some cases the Leyden White Dutch Cabbage kind has also given great satisfaction. A hardy constitution is of great importance, but the half-tender kinds are more acceptable for table. The variety of the White Paris Cos, generally known as the London Cos, is the best summer Lettuce in cultivation, owing to its excellent quality and fine colour. The Bath Brown Cos is an excellent Lettuce for standing the winter, and if bound round with a withie or piece of matting when nearly fit for use, it forms a large fine heart of beautiful white crisp leaves with pinkish midribs, and it is grown in large quantities in market gardens on this account. The sowings of Lettuces made between August and December are made on beds, and the young plants are transplanted where they are to remain; but the spring and summer sowings are made where the plants are to stand till they are fit for use, in rows from 16 in. to 18 in. apart, and the seedlings are thinned out in the row to 1 ft. asunder. In this way, and by a careful selection of seed, the plants seldom "run," and are had in use throughout the summer. The demand for Lettuces depends for popularity very much upon the character of the weather; in cold periods they are not so much sought after, but in warm weather there is a great demand for them. In some market gardens banks are thrown up on which to grow Lettuces, and some of the tender Cabbage kinds withstand the winter in that way. In open places, especially where the soil is wet, it is usual to round up beds on which both Cabbage and Cos Lettuces are planted, as in this way less moisture is retained around their roots than when they are planted on flat ground. Lettuce banks have a sharp incline, without special reference to aspect, the important point being to secure shelter. In order to obtain this the banks are thrown up under Apple trees, Currant bushes, &c., and under hedges, and in some cases small Laurels are planted closely along the tops of the ridges and in such a manner as to project over the bank. These Laurels afford good protection, as they retain their foliage all through the winter. Under such circumstances, a Lettuce crop is got off early, and the soil can be again partially levelled to furnish a crop of dwarf Beans or other summer produce. Around Gunnersbury and Kew acres of open spaces may be seen in the spring cropped with Lettuces alone, and long beds of seedlings in various stages under the hedges are kept to supply plants for seasonal crops.

CELERY.—This is considered by market gardeners to be one of the most remunerative of crops where both soil and situation are suitable for its growth. The Valley of the Thames is considered to be in all respects well adapted for Celery culture, and many acres of land in the Fulham fields and elsewhere are occupied by it. The sowing for the first crop of Celery is generally made early in February; a large main sowing is made in March, and for the latest crop sowing takes place in the middle or end of April. The early and main sowings are usually made in frames on hot-beds, but for a late crop the seed is sometimes sown in the open air on manure beds or in similar positions; the seed is sown at all times rather thickly in moist, light soil, and is but lightly covered. When up the seedlings if too thick are thinned out

to 1 in. or so apart. Some dig out trenches and fill them with fermenting material, on which they place a few inches thick of light, rich soil, and after sowing the seed cover the bed with mats or rough litter until the seed has germinated, when the coverings are removed during the daytime and replaced at night should the weather be unfavourable. In all cases the beds on which Celery seed is sown are made firm either by treading or rolling, and a little light soil is sifted through a fine sieve over the seed after it has been sown. The seedlings in all cases are freely exposed to light and air in order to render them stout and stocky. Those from the first sowing, when large enough, are pricked out in frames on a bed of rotted manure, and those from the main and later sowings are pricked out in May and June on beds similarly prepared on a sheltered border out-of-doors. In these positions they receive abundance of water in order to keep them growing, for a check at any period in the growth of Celery plants is very detrimental. The plants are usually pricked out in rows from 6 in. to 8 in. apart, about half that distance being allowed between the plants in the rows. When planting time has arrived a spade is run between the rows and a good soaking of water is given, after which nothing more is done for a few days. A spade is then pushed under the plants, which are thus carefully raised, separated, and taken on handbarrows or in boxes direct to the trenches. When planted a good watering is given them, and thus they sustain a very slight check through removal; but market gardeners seldom plant Celery in double rows as is done in private gardens, one row in each trench being considered the most profitable way. The strongest plants are in all cases selected and placed in trenches by themselves, and the weaker ones by themselves. In that way a succession is formed, uniformity in the size of the heads is secured, and thus a whole row of plants becomes marketable at one time. They need no sorting, and the ground being cleared is made available for other crops.

The ground on which it is intended to plant Celery is, if possible, prepared in autumn by being heavily manured and trenched, the surface being either thrown up in ridges or left in as rough a state as possible until spring, when it is levelled down to be sown with Radishes. In that case the land is marked out into a series of beds from 5 ft. to 6 ft. wide, leaving a good wide alley between them. In these alleys is placed an extra supply of manure, and in them are planted the earliest Celery plants. By the time these require earthing up the Radishes will have been marketed and the ground cleared of weeds, &c. I have, however, seen whole fields marked off in beds and the trenches dug out in winter in readiness to receive the Celery, the beds being planted with Lettuces or early Cauliflowers. Market gardeners never plant Celery in deep trenches; on the contrary, they contrive to allow the roots after the crop is fully earthed up to be considerably above the bottom of the ridges. Especially is this the case as regards late crops, which in damp badly drained soils are very precarious. During the growing season Celery is abundantly supplied with water, as are also the crops of salad plants, or French Beans, which are invariably grown between the lines. Earthing up is performed for the first time when the plants have become fairly established and are 6 in. high; the sides of the trenches are chopped down on the morning of some fine day, well broken up, and allowed to dry for an hour or two, when two men, one on each side of the row, push the soil with the back of a wooden rake to within a few inches of the plants so as to leave a ridge for the reception of water. At the next earthing the soil is pressed tightly round the bases of the plants, and more of it is chopped down from the ridges; and at the third, which is the final earthing, the ridges are made firm and smooth in

such a way as to effectually throw off the rain. The red and white varieties of Celery are the principal kinds grown, and under the treatment just recorded they become very crisp and solid. Sometimes a crop of Celery is grown for culinary purposes early in spring, and in that case the seeds are sown in June, and the young plants are pricked out rather closely together; they are never earthed up more than once, the object being to secure plants with flavour rather than crispness and good quality.

C. W. S.

PLATE CLXXXVII.

HIMALAYAN PRIMROSES.

(WITH A COLOURED FIGURE OF PRIMULA ROSEA.)

Drawn by CONSTANCE PIERREPONT

PRIMROSES abound nearly all round the temperate zone of the Northern Hemisphere, and one species occurs in the Southern Hemisphere in the extreme south of America. The Alps of Europe and the lofty Himalayan Mountains form, however, their two principal centres of concentration, though Eastern Asia (China and Japan) has supplemented the rich variety of Primroses drawn from these regions by at least two noteworthy species, namely, *Primula sinensis* and *P. japonica*. But it is to the Primroses of the Himalayan region we would now direct attention. It contains probably not fewer than thirty distinct forms independently of colour variations. The Himalayan Primroses are nearly all of an Alpine character, growing at an altitude above sea level of 6000 ft. to 18,000 ft., but chiefly between 9000 ft. and 15,000 ft. Flowering plants, it may be noticed in passing, grow at a greater height in the Himalayan Mountains than in any other part of the world, a few species ascending to the enormous elevation of nearly 20,000 ft.

P. denticulata is one of the commonest, most widely dispersed, and most variable in size and other characteristics of the Himalayan Primroses. It belongs to the same group as the British *P. farinosa*, but it is a much more showy species, even in its most diminutive state. The dark lilac-blue flowers are very numerous, and borne in dense heads on long scapes standing well above the leaves. This species appears to have been the first introduced from the Himalayan region into European gardens, as it was figured in Smith's "Exotic Botany, 1805, vol. ii., plate 114. It inhabits sunny situations and begins to blossom in early spring as soon as the snow melts. Sir J. Hooker collected it in Sikkim at an elevation of 16,000 ft., the plants being from 4 in. to 8 in. high, and the leaves from 1 in. to 2 in. long. At its lower habitats it attains nearly three times the largest size indicated for its highest. *P. capitata* is a variety of *P. denticulata*, the flowers being quite sessile, and forming a close head like a Scabious. *P. erosa* is sometimes regarded as a variety of *P. denticulata*, but it has coarse leaves similar to those of *P. vulgaris*. There is a fine dwarf variety of *P. denticulata* in cultivation at the present time under the name of *P. cashmeriana*. *P. purpurea* is an allied but perfectly distinct species with purple flowers nearly 1 in. in diameter, and sometimes the scapes bear two umbels one above the other. This also inhabits very elevated situations. *P. Jäschkeana* appears to be the same species.

P. Stuarti is a handsome yellow-flowered species of the same group. Its flowers are of a deep yellow, nearly 1 in. in diameter, and borne in loose umbels. *P. sikkimensis* is perhaps the finest of the large growing Primroses of our region. It was discovered and introduced by Sir Joseph Hooker, and figured in Bot. Mag., plate 4597. The discoverer writes of it that "it is the pride of all the Alpine Primulas, inhabiting wet boggy places at elevations of from 12,000 ft. to 17,000 ft., at Lachen and Lachong covering acres with a yellow carpet in May and June. It grows as tall as *P. japonica*, though the scapes usually bear only a solitary terminal umbel. Occasionally there is a second umbel of a few flowers. The flowers are of almost exactly the hue of the common Primrose.

Primula rosea, the subject of the accompanying plate, is, however, the gem of Himalayan Primroses on account of its lovely colour and neat habit. It inhabits the north-west Himalayas, and extends into Afghanistan, growing at an elevation of 8000 ft. to 12,000 ft. From the various collectors' notes it would appear to be a late summer flowering variety. *P. elegans* is a closely allied plant having smaller flowers. *P. speciosa* is a handsome Primrose of the same type, of dwarf habit, with large, deep blue-purple flowers. This has not yet been introduced. *P. petiolaris* is an aculeoscent species with distinctly stalked leaves and pale blue flowers, each petal having two deep notches at the tip. *P. floribunda* is a remarkable species, growing at the comparatively trifling elevation of

2500 ft. to 6000 ft. in north-west Himalaya. The yellow, fragrant flowers are small, but exceedingly numerous, each root throwing up several scapes, each of which bears three to six or more whorls of flowers. The whole plant grows from 4 in. to 8 in. high. *P. reticulata* and *P. rotundifolia* are dwarf umbellate Primroses, growing at a great elevation in Sikkim, the former having yellow and the latter purple flowers. We are not aware that either of them is in cultivation, though they are both described as most beautiful. This by no means exhausts the list of Himalayan Primroses, but we will only mention some of the very diminutive species, of which there are several singular and beautiful ones. Foremost amongst these is *P. uniflora*, a species collected by Sir Joseph Hooker, in Sikkim, at an elevation of 15,000 ft. The dried plants are from 3 in. to 6 in. high, and consist of a rosette of exceedingly small leaves, and usually of a single slender scape bearing on a relatively larger flower resembling those of a *Soldanella* rather than a true Primrose. *P. minutissima* is a native of the north-west Himalaya, at an elevation of from 15,000 ft. to 18,000 ft., in the Donkia Pass. The whole plant when in flower is sometimes not more than $\frac{1}{2}$ in. high, and rarely more than $1\frac{1}{2}$ in. high; but as it grows in tufts and its lilac and pink fragrant flowers are numerous, it forms a pretty object on the rocks. *P. Stracheyi* is another attractive dwarf species, distinguished by its relatively large flowers rising from the intricately tufted prostrate stems. We had almost forgotten the charming *Primula mollis* (Bot. Mag., pl. 4798), with soft hairy leaves of the shape of those of *P. cortusoides*, and bright rosy flowers in two or three whorls.

W. B. HEMSLEY.

GARDENING FOR THE WEEK.

Greenhouse.

Tuberous Begonias.—In addition to the immense quantity of seedlings raised by those who grow them in that way there are a large number of fine named varieties now becoming plentiful, varying very much in their general character from the long, pointed-flowered, drooping forms to those of the very broad-petalled kinds, the flowers of which in some cases are almost erect. The former are generally much the more profuse in flowering and are more elegant. Taste in this, as in other matters, may vary, but there is no reason why a portion of each should not be grown. They are a very acceptable addition to greenhouse subjects, not only from the variety of bright as well as delicate colours which they afford, but also from their distinct habit and long continuance in bloom. But although their natural habit is to keep on flowering for months, their ability to make a full display for the greatest length of time of which they admit depends to a considerable extent upon sufficient nutriment at the roots. The pots in all cases must be large enough, proportionate to the size of the plants. I mention this particularly, as, through their free disposition to flower, beginning to bloom, as they do, almost as soon as the young plants are fairly in growth, it is not an unusual occurrence to see them allowed to remain in the comparatively small pots they begin to flower in, and so get completely exhausted before the season is over; but before they suffer in this manner they should be moved into others of a larger size. If the operation is carefully done without much disturbance of the roots they will receive little or no check, in which way they may be grown to a large size where required. Clear, weak manure water will also assist them, but will not make up the deficiency where the quantity of soil available for the roots is much too small. Where any particular variety is required to be increased, this can be done by cuttings as they strike freely, but the tubers formed do not in all cases grow. Some growers prefer to increase them by leaf cuttings, the tubers from which are smaller, but more disposed to go on afterwards. To keep them moderately bushy a good light position is necessary, as the shoots keep on extending as they bloom, and there is usually a reluctance to pinch out the points with a view to make them break back, for by so doing the flowers to a certain extent are for a time reduced in quantity.

Epiphyllum truncatum.—Through the amount of neglect that these plants will bear without causing their destruction, they sometimes during the busy season receive so little attention as to make a great deal of difference at the flowering time. The growth of those that were forced early will by this time be completed, and their general condition will be improved by exposing them to all the sun possible. The position that will suit them best, if such can be spared, is an empty pit with the lights well tilted, so that they can get plenty of air, in which way they will be neither liable to get saturated with wet by thunderstorms, nor to be blown over and broken by the wind when out-of-doors, an accident to which they are liable from their heads, when large, getting so heavy proportionate to the small pots they generally occupy; but where a place of this

description is not available they can be set out under a south wall, tying those that are got big and heavy to sticks to keep them from being blown about in the manner indicated.

Large-flowered Pelargoniums.—Those that bloomed the earliest should, as their flowers get over, be placed out-of-doors in the full sun to ripen their growth previous to heading back. It is much better not to delay this operation with the earliest-flowered examples longer than when the principal head of bloom gets shabby, as upon getting the shoots ripened and their being cut down at the proper season depends their ability to flower early next year; do not in the first instance, as is frequently practised, withhold water so as to cause the foliage to flag and die off through the deprivation of moisture, but as soon as the leaves drop give a little, gradually withholding it until growth is so checked that the foliage will retain an erect position even when the soil is quite dry.

Fancy Pelargoniums.—These plants, with their beautiful delicate colours, are now so little in favour that they are comparatively seldom met with; still, to those who like to grow some subjects of a naturally formal habit by way of contrast to others of more free and elegant outline, with a disposition to produce a complete sheet of flowers of the softest tints, it would be difficult to point to any plant that will supply the place of these Pelargoniums. In their case it is not necessary to allow the soil to get so dry through the absence of water as in that of the stronger-growing selfs, and if exposed out-of-doors care must be taken that they do not get too wet during heavy rains, as they are very impatient of over much moisture at the roots, the effect of which is generally the destruction of the fibres, and that kills the plants.

Mignonette.—Where large examples of this are grown for winter flowering they necessarily require a much longer time to grow than the small pots of late summer and autumn-sown Mignonette generally in use; but where there is an attempt to grow this plant to a considerable size, although comparatively easily managed, unless its wants are constantly attended to, the specimens will be more remarkable for size than condition, as evidenced by the spare, yellow-looking leaves and small spikes of bloom that weak, attenuated plants often display. Mignonette does not like much disturbance as regards the roots, and it is well to get the early-grown stock in sufficiently large pots before the season is too far advanced, so as to avoid any cramping at the roots, for should this occur it is a difficult matter to get them to move freely afterwards; use the soil fairly enriched and pot firmly, giving the plants a good light position, placing them far enough apart in the house or pit in which they are grown; stop and tie out the shoots as growth progresses. The ordinary bushy or pyramidal form will in most cases be found to look the best. The ugly wire trellises sometimes used for Mignonette where at the time of blooming it frequently happens that the wire is as conspicuous as the shoots of the plants, cannot be too much condemned. Look well to the undersides of the leaves for greenfly and red spider, which, if present, very quickly ruin the plants. I have found that water, to which has been added a handful of soot to the gallon, stirred up daily for a week, and the plants from time to time syringed with it, has an excellent effect in removing these insects, and also in rendering the foliage unpalatable to them. A little soot-water applied to the soil both assists growth and helps to keep the leaves of that dark green colour which adds so much to their appearance as well as to the requisite strength. A little more seed may with advantage now be put in to grow some plants on in small or medium-sized pots with a view to their blooming before those latest sown.

Cinerarias.—The earliest sown plants should not be kept longer out of their blooming pots than when they have got the soil in those they already occupy fairly filled with roots, for with these again any check will result in the destruction of their lower leaves, the loss of which not only destroys their appearance, but so far weakens them, that it is never possible to get plants which have thus suffered to produce anything like the head of flowers they otherwise would do. Keep the early and later-sown stocks where they can be slightly shaded from the sun during the hottest part of the day, particularly in the case of plants that are treated so as to make free vigorous growth, for where the foliage thus gets to a large size it is, as a matter of course, softer than when of a small stunted character; some well-decomposed leaf-mould added to the soil as well as thoroughly rotten manure assists free growth. Where grown from suckers, and the plants from which these are taken were, after blooming, as they ought to be, planted out, the suckers much sooner attain a good size, and they will in every way be easier managed than when kept in pots. As soon as any of the suckers are large enough take them off, allowing the small ones succeeding to remain longer. When so grown I have found it well not to remove them from the old plants until they have attained a good size and plenty of roots, plants from such invariably keeping the lead of those taken off whilst small and weak. Where means have been taken to grow seed as advised

earlier in the season from plants of the best habit and finest flowers, the seed as it ripens must be regularly gathered, otherwise if allowed to remain it will fall.

Primulas.—Plants raised from the earliest sowing will soon be ready for moving into their flowering pots—5 in. or 6 in. in diameter will be large enough; ram the soil tolerably hard, by which means I have found them less disposed to produce leaves with long weak stalks that have a tendency to damp off; in potting keep the plants well down, so as to avoid any bare stem betwixt the soil and lower leaves; frames or pits facing the north, with the plants raised close up to the glass, and thinly shaded during the middle of the day, will be found the right position to place them in, the result being growth which will not only afford a full complement of flowers, but which will be much less disposed to damp in the winter.

Chrysanthemums.—Although these plants from their natural free-flowering disposition will bloom almost under any treatment, still there is a wide difference between the display they make when well cared for and the meagre number of indifferently developed flowers forthcoming when their wants are not well attended to through the growing season. Growing, as is their nature, very fast both roots and tops, any insufficiency in nutriment, especially water, has a more injurious effect upon them than on other soft-wooded subjects that progress less rapidly. There is a good deal of difference in the treatment adopted by different growers, particularly in the use of manure water; some never give it until after the flowers are set, under the impression that the plants will bloom better by using ordinary water up to this stage. I have tried this method and also that of using manure water from the time the roots are getting fairly established in the blooming pots, giving nothing but manure water after they had arrived at that state, and I have found the latter treatment considerably the best, both by enabling them to retain their foliage, which makes them look so much better when in bloom, and also by the greater number of large, full-formed flowers which any given variety will produce in pots of similar size to those occupied by plants less liberally supplied with manure water. In the case of any species of plant where, through the use of continuous strong stimulants, there is a danger of the production of gross luxuriant foliage in place of flowers, it is much safer not to use manure water, except in limited quantities, until the bloom-buds are formed; but Chrysanthemums are so naturally free that nothing of this kind takes place. Yet it must be borne in mind where very liberal treatment of this sort is practised that it necessitates still more diligence in seeing that the soil never gets dry, for if this occurs the plants will suffer more than such as are less vigorous. Nothing tends more to preserve the foliage, to assist growth, and to minimise the drying influence of hot weather than keeping the pots plunged up to their rims; if coal ashes be available they are much the best, as they keep out worms, which, though not injuring them to the extent of more delicate-growing subjects, are still much better absent from the soil. The plants should now be treated in accordance with whatever form they are to be grown in; but for the usual decorative purposes on no account should I advise the stiff, flat training often seen resorted to for exhibition, and which, even in the case of plants so required, might with advantage as regards effect be dispensed with. The ordinary bushy form of tying, by the use of a few sticks keeping the branches sufficiently far apart to allow plenty of air to get to the whole, is the most generally useful; but some dwarf standards that are grown to a single stem from 2 ft. to 2½ ft. or 3 ft. in height, and stopped so as to cause them to branch freely, are particularly useful when the plants are to be used in rooms, halls, or corridors, and also for relieving the too-even surface which a stage full of these plants when in bloom often presents; for large conservatories and other structures still more might be done in this direction by confining some to single stems without stopping, keeping the shoots as they appear removed from the lower portion of the stems, simply allowing the head to branch out before the time of flowering. If the plants are at all affected with green fly the shoots should be repeatedly dipped in Tobacco water, which they will bear using stronger than most plants, until the insects are completely destroyed, to keep them clear from which the whole stock should be syringed freely with clean water every evening when the weather is dry. It is well not to grow a greater number than is required or there is time at command to give sufficient attention to, for, as with most other things, a better result may be attained with a limited number of plants well grown than larger quantities worse managed.

Cœlogyne cristata.—Where a sufficient stock of this is grown to give a succession of flowers through the winter the plants, as they finished their blooming, will have been gradually introduced into heat; by this means the early and later completion of growth will favour the successional production of flowers much easier, and be more conducive to the health of the plants than by retarding alone when growth is complete. This Cœlogyne delights through the grow-

ing season in plenty of moisture and plenty of light, but not too much heat.

East Indian House.—Most of the plants here will now be in active growth; the position and description of the house in which they are cultivated should always be taken into account in determining the temperature to be kept up the lighter the house the more heat the plants will bear without producing weak, soft growth; 65° by night when the weather is not so hot as to cause the thermometer to range higher than this will even at this season of the year be more conducive to continued health than when they are kept warmer. Orchids are naturally slow-growing subjects, and young cultivators are frequently so desirous to get their plants on in size that they urge them on by heat and moisture and insufficient air, which for the time being results in an apparent gain through the size they attain in a short time, but is quite the reverse of a permanent advantage, for the large leaves so produced are deceptive, as they sooner decay and fall off, leaving the tall-growing non-bulb forming section, making it naked and bare at the bottom. Vandas, Aerides, Angræcums, and Saccolabiums, which are the principal representatives of this habit of growth generally, owe their unsightly appearance to this cause, and when the flowering abilities of plants so treated are taken into account, in this they are found equally wanting. Plants grown slower, with shorter but very much thicker and stouter foliage, will produce flower-spikes from the base of almost every leaf, whereas the examples grown under a system that induces a softer, weaker texture will often not bear more than half the number. Regulate the day temperature in accordance with the weather; when it is cool and dull 75° by the use of fire-heat will be enough, whilst with a clear sky and a high outside temperature 85° or 90° will be rather beneficial than otherwise, giving air each day in accordance with the state of the weather.

Dendrobiums.—Most of the warmest sections of these should now be in full growth; the thin-leaved kinds, like *D. Devonianum*, are very susceptible to the attacks of yellow thrips, and if this little pest exists at all in the house it is sure to find them; it is equally injurious to the young leaves of *Phalanopsis*, and also affects *Vandas*, *Aerides*, *Saccolabiums*, and others, the leaf development of which takes place in the manner of these; but if syringing is practised daily at the time of closing the house, not only does it check the increase of the insects, but it prevents their doing injury, as they cannot endure the presence of water. This is the only effectual method I ever found of dealing with them, as many Orchids do not like Tobacco smoke, or will bear it in anything like a volume dense enough to kill this species of thrip, which gets down as low as the unexpanded leaves will permit, where there is enough air to enable it to live beyond the reach of the Tobacco fumes.—T. BAINES.

Flower Garden.

The present, in ordinary seasons, is comparatively a leisure time; but, though planting is done, such will not be the case this year, if neatness be maintained, for weeds grow so fast, both on walks, beds, and borders, and the lawn and edgings require such constant cutting, that leisure is out of the question, and resolute energy must take its place in order to keep anything like abreast of the work required to be done. Another such protracted cold, wet season, and the modern system of flower gardening must collapse, at least so far as the use of tender plants is concerned, for up to the present time they have grown beautifully less since being transferred to the open air, and however favourable the weather may now become, the season is too far advanced for them to attain perfection ere the time arrives for their return to winter quarters. *Pelargoniums*, *Caleceolarias*, *Petunias*, *Lobelias*, *Violas*, and *Verbenas* are about the only plants that are growing satisfactorily, and all these should be made the most of by pegging them down in their proper positions and frequently removing all seed vessels and bad flowers. Keep the soil stirred in all the beds; heavy rains have so hardened the surface that it is impossible for the little sun-heat which we get to penetrate it. In mixed herbaceous borders *Pyrethrums* now make a good display. Why is it these are not more generally grown? They do well in any soil, are perfectly hardy, there are amongst them an immense number of varieties, and the flowers are brilliant and lasting. Their flower-stems now require supports, and the same may be said in reference to *Potentillas*, *Delphiniums*, and the earlier *Phloxes*. Brier stocks are now quite sufficiently advanced for budding, but the buds are late, scarcely a flower having yet been cut from the open border—and, as a rule, the best buds are those from the shoots that have been denuded of their flowers; as soon as these can be had, budding should be performed. This will, no doubt, prove a favourable season for that operation, as the excessive rainfall will conduce to the easier working of the bark, and the moist atmosphere to the quicker and more certain starting of the buds. The first bloom of climbing *Roses* on south and west walls will now be nearly over, and, by way of assisting the plants to produce a good second supply of bloom,

remove all the old flower-stems and useless spray at once, and well soak with manure water. The fact of the ground being wet through recent rains need not be taken into account; such a condition will cause a quicker utilisation of the manure, and so prove beneficial rather than otherwise. Box edgings should now be clipped, and Privet, Holly, Yew, and other evergreen hedges be trimmed into the desired form. All Coniferous shrubs are making the most luxuriant growth, and many of them, particularly young specimens, would well repay any attention that can be bestowed on them in the way of stopping any shoots that are growing more vigorously than others on the same tree, so as to balance the growth and render the tree symmetrical. Azaleas and Rhododendrons should be deprived of their seed-pods, and the grafted kinds should be kept free from the suckers which the stocks are producing so freely this season.—W. W.

Auriculas.—At this season of the year Auriculas are sometimes neglected, and that is just what they cannot endure. Let the plants stand in the sun until they become desiccated from want of water at the roots, and a good bloom next year need not be looked for. The north side of a hedge or low wall is the best place for them now, and when the sun gets round about 2 o'clock p.m. it is necessary to shade until after 4 o'clock if the weather is sultry. It is not well to give too much water; one can easily err in this direction, and more so now than at an earlier date. Remove dead and decaying leaves, and keep everything about the frames clean. Still pot on and propagate offsets, placing the latter under close bell-glasses or hand-lights until they are established; the newly-potted plants should also be placed in a close frame for a few days until they have become established.

Carnations and Picotees.—See that the flower-stems of these are securely fastened to sticks with matting, and that all superfluous flower-buds are removed. The bloom will be later this year than usual, but the weather being favourable, an abundant harvest may be the result. Plants in beds are rather later than those in pots, but in both cases they are looking strong and healthy, and must not suffer from lack of moisture at the roots, especially those in pots. Continue to put in the small growths that are not likely to be useful as layers in the same way as recommended in the case of Pinks.

Hollyhocks.—As these progress in growth side shoots are formed, which must be removed as soon as they are strong enough to form eyes for purposes of propagation. The leaves nearest the stem have eyes at their base that under proper treatment would produce a stem; those further removed have flower-buds at their axils. The leaf-buds should be taken off with 1 in. of the stem attached and inserted in fine soil in pots. If the pots are placed in a close frame the young eyes speedily start into growth and form plants in a few weeks. If fine spikes be desired, it is essential that the side growths be taken off, even if the eyes are not wanted to increase the stock. Give manure water to the roots or place rich manure round them and water through that.

Gladioli.—The hoe must be kept at work between the rows of these until every weed is destroyed. There has been no lack of moisture in the soil as yet, but as soon as dry weather sets in give a good soaking and then mulch, in order to retain moisture. If the weather continues dry and hot it may be necessary to water freely twice a week. Sticks must also be placed to the flower-stems as soon as they can be seen. Look out also for a green caterpillar that insinuates itself underneath the flower-bracts before the flower-buds can be seen, and quite destroys the symmetry of the spikes.

Tulips.—The lateness of the season is evidenced by the blooming of the Tulips this year. One of the largest growers writes me from Manchester this week saying that he could cut a fine box of blooms on July 1, a state of things quite unprecedented in all his experience of more than a quarter of a century. In ordinary seasons the bulbs are taken up between the 24th of June and the 1st of July. Notwithstanding, however, the season being so late, the bloom has been good. Our own bulbs have been taken up and stored away until planting time, and the beds in which they grew have been planted with Asters.

Hardy Cyripediums.—Except the beautiful *C. irapeanum*, these are all now out of flower, but they still require the same attention that they have hitherto had, that is, syringing the leaves twice a day and seeing that the plants do not suffer from want of water at the roots. The longer the leaves are kept in a green and healthy state so much the better is it for the permanent well-being of the plants. There are a few of the scarcer species still difficult to manage, such as *C. arctinum* (the Ram's Horn Lady's Slipper), *C. japonicum*, and *C. irapeanum*. If any readers of THE GARDEN have been successful in growing any of the above, information as to the treatment which they have received would be very useful.—J. DOUGLAS.

Hardy Fruit.

The continued unfavourable weather which we are having is causing fruit prospects to grow every day gloomier in this district. Apples and Pears are dropping wholesale; Apricot branches are dying off more largely than usual; Peaches are badly attacked with aphides, and the crop is sure to suffer somewhat through the strong and oft-repeated measures necessary to eradicate them; Strawberries are a heavy crop, but much of the fruit is rotting before it is half grown; Morello Cherries and Currants are about the only fruits that continue uninjured. Still, we have not yet lost hope, for with a change to hot sunny weather the fruit crop would yet be an average one. Incessant warfare must still be waged in the case of aphides. Soap-suds or clear water applied with force are the best antidotes, but they require frequent repetition, and before washing and dressing the trees all the curled and blistered leaves, and the worst effected and superfluous shoots should be removed, and the final tying in of shoots should be delayed until the trees are quite clean and healthy. Pears are now sufficiently advanced to have all the breast-wood cut away at about, say, four joints from the main stem; if cut closer they are apt to again break into strong wood growth rather than form fruit-buds. The excessive rainfall of the present season will doubtless contribute to the production of an unusual quantity of wood growth, and extra stopping will be necessary not only to induce the formation of fruit-buds, but to assist the ripening of the new growth by the freest possible exposure to light. Currant and Gooseberry bushes have made more growth than I ever remember them to have done in any former season, and thinning it out will therefore be a matter of necessity. Summer pruning of these has many advantages, not the least being that the trees can be trimmed into any shape desired, and the fruit at the same time be exposed to the influences of the atmosphere. Currants and Cherries are changing colour, and will require protection from birds; any that are to be reserved for a considerable time should be cleared of aphides and be closely covered up with hexagon netting. Ripe Strawberries often suffer more from mice and slugs than from birds, and it will be desirable to at once adopt precautionary measures against these; trap the former with the common figure of 4 trap, and the latter by means of baits of bran. To all appearances Raspberries will be a very heavy crop; they evidently enjoy the rain, as they are not only full of fruit, but growing vigorously. If the stools have not yet been thinned they should at once be reduced to four each, or if thickly together three will be ample. Mulch the ground about them with good rotten manure, for a change of drought would soon have a deteriorating effect.—W. W.

Parks and Open Spaces.

Grass has grown vigorously during the past month, and is still continuing to do so, necessitating frequent mowing and rolling to keep it in good condition; now is the time to form a good sward, and the closer and oftener it is cut and rolled the better will the bottom be, and the more effectually will it withstand the ensuing winter, should it be severe; few things add more to the beauty of parks and open spaces than good and well-kept Grass, and the work is so simple that it should be by no means neglected. The continuous moist weather has also been favourable for eradicating weeds. On large open spaces where it is not practicable to maintain the Grass in a lawn-like condition, it should be mown at least two or three times during the growing season, or serious injury will result to the turf, the coarser Grasses destroying the finer varieties so essential to the formation of a good and durable sward. Where the soil is gravelly and poor a light dressing of artificial manure will be found beneficial; in damp soils Moss may be destroyed by sweeping with Birch brooms half worn out, rolling the ground the following day.

During wet weather it is almost impossible to maintain plantations and borders free from weeds; in those instances where they are much over-run the best plan will be to lightly dig them over, taking care not to injure the roots of trees, shrubs, or herbaceous plants; where this cannot be done the weeds must be hoed up and raked off or hand-picked. Overgrown shrubs may be pruned back to within proper limits and all herbaceous plants requiring it should have supports. Annuals must be thinned out, and all subjects in the way of Asters, Stocks, Helichrysums, &c., still in store should be planted out in favourable weather without delay. Seeds of perennials may also be freely sown for stock next year or for spring bedding.

Trees recently planted will require great attention at this season, especially those standing singly as in avenues, in order to secure them against damage during high winds; the heads having become heavy in consequence of the luxuriant foliage caused by the moist weather, it may indeed be necessary to thin out some of the superabundant wood to allow the wind to pass freely among the branches; this is not generally advisable, however, if it can be avoided, the best method being to stake them firmly or make them secure with three stays of cord or wire placed triangularly; attention should also be given to the ties to prevent the strings cutting into the trees.

Climbers and creepers must not be neglected at this season, nailing or tying in those shoots which are the strongest and in the best positions, cutting out those which may not be required. This work should be carefully attended to, particularly in the case of those growing freely at the top, as Virginian Creepers, Clematises, &c.; no wall or other unsightly structure should be bare at this period of the year, and edgings of Ivy, Euonymus, and other small shrubs should also be thinned out, cleaned, pegged down, clipped, and neatly arranged as may be necessary.

Corrosive acids or salt may be used during July for the purpose of destroying vegetation on roads and walks, choosing hot, dry weather for its application, whilst wet will be preferable for handpicking—the most desirable mode of getting rid of weeds when they are not in any great quantity; use the roller as often as possible after rain, and examine gullies to ensure the water running off rapidly during heavy storms.—C. DENNIS, *Southwark Park*.

TREES, SHRUBS, AND WOODLANDS.

PRUNING FOREST TREES.

GREAT difference of opinion prevails as to the necessity for pruning forest trees and the season at which such operations should be carried out. But undoubtedly the weight of authority is favourable to early summer pruning. The month of June is strongly recommended, because at that time the wounds heal up much quicker than during July or August, when the motion of the sap becomes slower. And it should be a standing rule with the pruner that no wound remain exposed to the action of the atmosphere for a longer period than one year. If the aim of the owner of woodlands was confined to the production of the greatest amount of wood upon a given area in the shortest possible time, it is questionable whether pruning of any kind should be executed; for every branch cut away from a tree lessens the quantity of foliage presented to the action of the sun and the atmosphere, and therefore decreases the absorption of carbonic acid gas and the formation of wood, of which carbon is the main constituent. But where the object in view is the growth of the maximum of straight, lengthy, clean, and sound timber, thinning and pruning must commence soon after planting and continue until the trees attain considerable proportions. By thick planting, early thinning, and careful stopping of rambling shoots or rival leaders, pruning will seldom be necessary except in the removal of injured branches. But as the growth of a tree is slow, and he who plants seldom lives to train up his trees to maturity, pruning in an advanced stage of their growth is often necessary in order to lessen the evils resulting from early neglect.

Trees differ so much in habit and in their rapidity of growth, and are so largely dependent upon the soil and situation in which they are placed, that it is impossible to lay down any precise rules for their management in this respect. Those intended to form large and good timber should never at any stage of their growth be suffered to become too much crowded, nor overtopped or whipped by their nurses; and as they rise they should be allowed sufficient space to enable them to develop well-proportioned heads, equal in length to from one-third to one-half the height of the entire tree. It should also be borne in mind that by preserving a complete canopy of foliage overhead the moisture is retained in the soil, the stems rise rapidly, and the formation of side branches is retained.

The advantages of early pruning are nowhere more observable than in young plantations of Oak and Spanish Chestnut. Two years after planting it is no uncommon occurrence to find a considerable number of the young trees hide-bound and becoming distorted in their growth. Such, if left to themselves, seldom or never attain to the size of timber trees. But if cut over with a clean section within 2 in. of the ground they will push forward vigorously during the following spring and summer. By rubbing off all but two of the strongest shoots in June or July, and allowing these to grow on together until the following March, and then cutting out the weaker of the two, and afterwards keeping the other single upon the stub, a vigorous growth may be insured, which will, in a few years, far exceed that of the uncut trees. A most remarkable instance of this is mentioned by Forsyth, who the second year after planting a bed of Oaks headed down one-half and left the other to grow naturally. In giving an account of their progress a few years afterwards, he states that one of the plants thus cut over was 18 ft. high and 15 in. in circumference at 6 in. from the ground, while the largest of the uncut ones was only 5½ ft. high and about 4 in. in circumference.

But, while recommending the early and careful pruning of forest trees, I would not be considered as an advocate of the excessive lopping and pruning introduced by Pontey, and so ruthlessly carried on by his successors, who looked upon and spoke of the branches of

trees as being merely “robbers of the stems.” To produce lengthy timber every branch which threatens to rival the leader should be shortened. By adopting this method instead of cutting away the branch entirely the trunk is strengthened by the sap being detained in its descent. Timely attention will obviate the necessity for heavy prunings at any stage of a tree's growth. The pruner should, however, be conversant with vegetable physiology, otherwise that twilight of uncertainty in which all his operations are performed may lead him to commit grave errors. In close plantations the destruction of the lower branches is eventually caused by the exclusion of light, but the result is generally unsoundness of stem. This is found to be the case so extensively in Canada and other large timber-producing countries, that a very small proportion of the trees grown under such circumstances are fit for exportation.

The whole art of pruning and training timber centres in the adoption of a proper mean between the two extremes of cutting away the branches of a tree so as to give it the appearance of a mere May-pole in the one case and that of a dense spreading bush in the other. A severe mutilation of the head of any tree must for a long time paralyse the action of its roots, and on this account the heavy pruning of neglected trees, if undertaken at all, should be extended over two or three seasons. Deciduous trees will require the most careful training in order to produce sound timber. As considerable difficulty is experienced in pruning trees of a resinous kind without injury to their growth, it becomes the more necessary to plant and rear them in close order. The lower branches under these circumstances are soon killed back, and may be removed so that the longitudinal structure of the bole is but little injured, as, by the early destruction of the laterals, the superincumbent layers of wood are entirely free from knots. Thus it happens that Fir timber grown in close plantations, where the early removal of the dead, bolt-like insertions left by the dead branches is attended to, becomes the most valuable, while single trees, from their coarseness of grain and abundance of large knots, are almost worthless to the builder. It is also found that Ash grown in close plantations becomes much tougher and clearer in the grain.

In exposed situations both the pruning and the thinning of trees should be much lighter around those margins of plantations which face the prevailing high winds of the district. By too close packing it often happens that only the face of the very outermost trees are clothed with foliage, so that any injury to one of these admits the destructive winds. This may be guarded against by a judicious early thinning of such margins, so as to secure a belt of low-branched trees.

Pluckley, Kent.

A. J. BURROWS.

WOODLAND WORK FOR JULY.

Now that the early summer operations connected with the stripping and harvesting of bark, the removal of timber and other produce, the repairs of hedges and stopping of clearance roads have been brought to a close, the forester should look well through his plantations and carefully prune away all injured branches, and afterwards remove dead wood and all strong undergrowths of weeds. During the present month considerable progress should also be made with fencing, draining, trenching, and hole digging. The season for which there is but little special work should be taken advantage of to forward the heavier operations of the year. The cartage of materials for future use may, during the dry summer weather, be done with the minimum of labour for the horses employed; and upon very heavy clays the short season that intervenes between this and the time for planting at the end of September or beginning of October will be quite little enough for the proper sweetening and amelioration of the soil thrown out. Whenever a new plantation is to be made upon the site of an old wood all vestiges of the former crop should be removed, and a thorough trenching or deep holing will prove the best preparation.

Hedgerows will require considerable attention this month. Clear all weeds from their bases, pare the sides well in with the switching bill, and reduce their tops to the narrowest limits consistent with proper strength for the situations in which they stand. Fences or screens of Bay, Laurel, Turkey Oak, Box, Holly, and Yew may be carefully trimmed with the pruning knife. Towards the end of the month, should the weather be showery, plant out Holly and other evergreen trees. A tolerably large ball and a copious watering at the time of planting will generally insure their safety.

Where the pruning of forest trees is carried on considerable progress should by this time be made with the work. The youngest and most flourishing should be left till the last. The dead and decaying branches may be removed from Fir trees, and if this operation be performed early, sound and serviceable timber will be produced.

Keep down weeds in the nursery, turn seeds of various kinds in the pits, thin out beds of young plants, bud the Horse Chestnut,

Hawthorn, &c., keep the heads of grafted stocks free from side shoots, and prune up young trees for autumn transplanting. Collect all available materials for composts and turn those formed early in the spring. Add gypsum, chalk, lime, and shells where they can be obtained.

A. J. BURROWS.
Pluckley, Kent.

THE INDOOR GARDEN.

ASPLENIUM LONGISSIMUM.

THE genus *Asplenium* contains many beautiful species all, with few exceptions, worthy of cultivation, and, being found in all parts of

Asplenium longissimum.

the world where Ferns grow, they are adapted for the hardy, temperate, and tropical Fernery. Some, from their trailing habit, make desirable basket plants, as will be seen by a glance at the accompanying illustration of *A. longissimum*, an elegant species with fronds measuring from 3 ft. to 6 ft. and sometimes 9 ft. in length. Its bright ebony rachises and olive-green shining pinnæ also add greatly to its beauty. It is a native of the Indian Archipelago, and was introduced into this country some years ago by Messrs. Veitch & Son, of Chelsea. The most suitable baskets for it are plain hemispherical wire ones, well painted, and the soil should consist of three parts turfy peat, one part light loam, and one part sand. Before inserting the plants the sides of the baskets should be lined with a layer of peat, and a few large potsherds should be placed at the bottom for drainage, an important point even in the case of baskets. The spaces between

the roots and sides of the baskets should be made up of the above compost mixed with pieces of charcoal or potsherds, in order to allow the air to permeate the soil. A few rooted cuttings of *Ficus minima* or *F. stipulata* would, if inserted in the sides and pegged down, hide the soil from view. *Panicum variegatum*, *Tradescantia zebrina*, *Selaginella Kraussiana*, *S. uncinata*, and *S. Galeotti* would answer the same purpose, and are, moreover, themselves attractive. The spores of *A. longissimum* rarely germinate, but it can be propagated freely from the bulblets, which are produced at the end of almost every frond; these grow rapidly, and in about three years make fine specimens. Several allied species are also adapted for basket culture, such as the graceful *A. furcatum*, which grows plentifully on trees in the warmer parts of both the Old and New World, and which has a very ornamental appearance; *A. flaccidum*, a fine species with deeply-cut, drooping fronds of a succulent character, also makes a good basket plant, as does likewise *A. nitens*, though smaller than the preceding; *A. rhizophorum* and its numerous varieties make desirable specimens, especially the variety called *raehi-rhizon*, the fronds of which taper into long whip-like appendages, the whole frond reaching some 2 ft. in length. *A. lineatum*, a native of Mauritius, with fronds from 2 ft. to 3 ft. long, cut into numerous linear segments, makes an excellent cool conservatory plant.

C. M.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Ouvirandra fenestralis and Berneriana—Amongst the many varied forms of plant life which inhabit our glass structures few will be found so capable of exciting the wonder and curiosity of the uninitiated as these two species of Lattice Plants. Unfortunately, they appear to be somewhat capricious in their likings, flourishing in a few favoured places with but little care, whilst in others the utmost attention fails in inducing them to grow satisfactorily. The Lattice Plants are seen to the best advantage when growing in a clear glass vessel well exposed to the light. The peculiar structure of the leaves is then more clearly defined, and a well-developed specimen thus grown and placed in a conspicuous position is no mean ornament to a glass structure. At Messrs. Jackson & Sons' nursery at Kingston-on-Thames both of the above-named species grew, and probably do so now, like weeds. They were planted out in inverted cloches in a compost of lumpy peat, and, with the exception of occasionally washing the glass and pouring in a can of fresh water now and then, no particular care was expended on them. Old stools, young plants, and seedlings grew alike with equal freedom. They were placed in a Vanda house close up to the roof. *Ouvirandra Berneriana* is the stronger growing species of the two, and at Messrs. Jackson's flowered and seeded freely, the seed sowing itself and germinating abundantly. A considerable number of young plants were raised, but many of them perished when removed to other establishments, although treated in precisely the same manner. Either rain or Thames water was used for them, and possibly greater success would be attained in their culture if only spring or rain-water was employed. Where the Lattice Plant does succeed it certainly enhances the value and interest of even the most choice collection of plants, and it is worthy of all the pains and any reasonable expense that may be incurred in its culture. *O. Berneriana* is, I think, the most easily grown, but the network of the leaves is not so strongly marked as is the case with those of *O. fenestralis*. The latter species has a most charming and graceful appearance when growing freely in clear limpid water, and is sure to obtain from visitors the greatest share of attention and admiration.—J. CORNHILL, *Byfleet*.

Hovea Celsi Grown as a Standard.—Plants of this beautiful blue-flowered New Holland shrub, in 6-in. and 8-in. pots, with clear stems, from 18 in. to 24 in. in height, crowned with a well-developed head of foliage, and covered with bloom, produce a fine effect either when forming the centre of a group of flowering and fine foliage plants, or when so arranged that the head of each plant is brought out slightly from the general arrangement. There are few plants that gain in beauty by being grown as standards. *Hovea Celsi*, however, appears to much greater advantage when thus treated than when the ordinary mode of culture is followed. Such, at least, was the conclusion I arrived at on seeing a considerable number of standard specimens at Mr. Laing's nursery at Twickenham. The plants were in various sized pots, all equally healthy and full of bloom, and they struck me as being highly ornamental, but at the same time as affording a somewhat novel feature in conservatory decoration.—J. C. B.

Dendrobium McCarthiæ.—This is certainly one of the most beautiful of Dendrobies, and one with which I have been fairly successful. I have grown a plant of it for five or six years in a Teak basket suspended from the roof of a warm Cattleya house. The first

year in which the plant was placed in the basket, the roots being merely covered with clean potsherds, it made good growth and plenty of roots, having been freely watered all through the growing season. When it started into growth the next year a little Sphagnum was placed over the rocks and freely watered. The plant flowered from the last season's growth, and it has done so more or less every year since, about midsummer. I fancy we have not kept the roots dry enough, nor placed the plants in a house having a sufficiently low temperature during winter.—J. DOUGLAS.

Odontoglossum cirrhosum.—The first living plants of this Orchid were introduced in 1875, and in the following year a plant of it was exhibited in flower at South Kensington, and obtained a first-class certificate. Shortly after this it fetched very high prices, but the many thousands of it that have since been imported have brought it within the reach of all lovers of Orchids. During the years 1877-78 some very fine spikes of this species were produced, but in almost every case they were far too long to be pretty. Now, however, it seems to have become inured to artificial treatment, and the result is shorter and stouter spikes, well set with fine blooms, which not only look well on the plant, but prove very useful in a cut state. The variety called Klabochozum, in compliment to the collector, F. Klabocho, has larger and better marked flowers than those of the species *O. cirrhosum*, of which the annexed is an illustration kindly furnished by Messrs. Veitch. It should be potted in equal parts of peat and Sphagnum, and the pot should be two-thirds full of drainage. It should be placed in a light position in a cool house, where it will get abundance of fresh air. It succeeds admirably suspended near the opening of a roof ventilator. It should have frequent and liberal supplies of water during the growing season. From the time when the bulb is fully developed until the spike is a few inches high, little water must be given; but at no time should this plant be allowed to get thoroughly dry, or it will lose both leaves and roots.—J. C. SPYERS, *Burford Lodge, Dorking.*

Gloxinias.—Visiting the gardens at Redlees, Isleworth, for the purpose of inspecting the magnificent display of herbaceous Calceolarias then in full bloom, I was much struck with a quantity of erect-flowering seedling Gloxinias then blooming for the first time, all showing grand flowers, some of great beauty and perfection of form. These, said Mr. James, are so far in advance of our named kinds that I have put them on one side altogether, and shall keep my stock supplied in future by means of seedlings. The seed of this lot came from Messrs. Sutton, of Reading, but the marvellously fine seedlings shown by Messrs. Veitch, Wills, Kinghorn, and others show that the days of named kinds are passed. The Gloxinia is with heat easily raised and grown, and as a decorative flower is, for its size, probably unrivalled.—A. D.

Mr. Wrigley's Orchids.—This important collection was disposed of at Stevens' last week, and realised upwards of £2300. The finest specimens of the rarer kinds fetched high prices. *Lycaste Skinneri alba*, two plants, brought £36 and £17 respectively; *Cypripedium Stonei*, £22; *Anguloa Clowesi*, £23; several plants of *Masdevallia Lindenii*, £26; *M. Veitchiana*, £15; *M. Lindenii*, £26; a fine plant of *Vanda navis*, £16; *V. tricolor*, £16; *Odontoglossum vexillarium* from £15; *O. pulchellum*, £11; *Cypripedium caudatum*, £8; *Calanthe veratrifolia*, £11; *Masdevallia tovariensis*, £9; *Laelia purpurata*, £8; *Celoglyne cristata*, £8; *Aerides Fieldingi*, £9; *Odontoglossum vexillarium roseum*, £7; *Dendrobium Schrederi*, £8; *Cattleya aurea*, £12; *Cypripedium levigatum*, £10; *Saccolabium præmorsum*, £12; a fine *Anthurium Scherzerianum* realised £29.

Effects of the Winter at Newry.—The past winter has been productive of many surprises; for instance, *Erodium Manescavi* planted in a wet bed only 2 in. or 3 in. above the water, has wintered safely, and is now in a vigorous condition and in full flower. So also in the same spot is *Francoa ramosa*, which is quite safe and coming up most vigorously, whereas the same plant on raised rockwork only a few feet distant is quite killed, and in both positions *Saxifraga sarmentosa* is growing freely. *Lobelia fulgens*, close to the side of the water, and, in fact, partly in it, is safe, whereas everywhere in ordinary soils and positions it is killed. *Mimulus cardinalis*, close to the side and in the water, is in the most vigorous health and quite 2 ft. high; so is *Mimulus cupreus* which is in full flower, and which has some of its shoots trailing in the water, though, curiously enough, *Epilobium hirsutum variegatum* in the same bed is dead. *Spiraea palmata*, planted just 4 in. above the water, and, of course, with its roots in it, is more than 2 ft. high; it has splendid foliage, and promises to produce fine heads of bloom. Some of the variegated *Funkias* have proved to be fine waterside plants; masses of *F. undulata*, variegata, alba, marginata, japonica, aurea, glauca, &c., with their roots in the water, are now truly beautiful. *Sarracenia purpurea*, planted on a bog bed raised only about 2 in. above the water, and which was a solid mass of ice for months, is now (several plants) coming into flower, proving clearly its hardiness.—T. SMITH.

THE FRUIT GARDEN.

EARLY RIPENING VARIETIES OF FRUITS.

WHERE there is a demand for ripe fruits as early in the year as it is possible to have them, it is of the greatest importance to make such selections of Pines, Grapes, Peaches, Nectarines, Strawberries, &c., as not only bear forcing well by artificial means from midwinter onwards, but which also come the most rapidly to a state of ripeness. In both these respects there are very marked differences in the different varieties of these fruits. No experienced forcer who wanted to present new Grapes at table in April or May would select for this purpose the Muscat of Alexandria, although it has probably more good qualities than any other white or even black Grape. Nor would the Barrington or late Admirable Peaches be selected, though these are noble varieties in their proper place. Of Strawberries, no one would select British Queen for ripening early in March, although it is probably yet the finest late or midseason Strawberry in existence. In their respective classes these are all first-class fruits, but they are totally unfitted for very early forcing.

Among Grapes, Black Hamburgh has yet no rival for early forcing as a black variety; Buckland Sweetwater and Foster's Seedling are popular white sorts for early work, and no doubt they bear forcing well and ripen early; but it seems strange that such very superior flavoured Grapes as the white and grizzly Fontignans are so seldom met with in early Vineries. They are both Grapes that stand forcing remarkably well, are sure croppers, and come early to maturity. Indeed, for our own choice we much prefer Royal Muscadine, and one or two other varieties of Muscadine, for flavour to either Buckland Sweetwater or Foster's Seedling. Where mere appearance is appreciated in preference to flavour, the two last-named may perhaps be preferable.

The popular early forcing Peaches have been, and are still to a great extent, Royal George, Abce, Early York, Stirling Castle, &c. No doubt these varieties have answered the purpose of early forcers well, and they are good when ripe, and until recently have been found among the quickest to arrive at a state of maturity. They are, however, completely out-distanced as regards earliness by such varieties as Early Louisa, Early Beatrice, Hale's Early, and Early Rivers. But we fear the two first-named are too small ever to become so acceptable as they otherwise would be. Hale's Early is a large, finely-flavoured, handsome Peach. On these points there cannot be objections raised against it. Its earliness is very remarkable. We have before us a ripe handsome fruit of it from a Peach-house at Chatsworth. From the warmest end of the same house we have, for comparison, a fruit of Elrge Nectarine, and from the middle tree of the house a fruit of Royal George Peach. The difference is more remarkable than in any similar comparison we have ever seen. Neither the Peach nor Nectarine from the warmest end of the house have finished the stoning period, while Hale's Early Peach is perfectly ripe, juicy, and luscious. The valuable qualities of Hale's Early Peach for early forcing and ripening is thus most strikingly manifested compared with one of the most popular early Peaches of the older class. We believe that Early Rivers is a Peach equally early, rich in flavour, and of large size. There can be no doubt that, whatever may be the fate of the lesser sized early Peaches, Early Rivers and Hale's Early will take a prominent position in the supply of early Peaches.

What is now wanted to match these two early Peaches is a Nectarine that will ripen nearly about the same time. The Elrge has long held a first position as a fine forcing Nectarine, and most deservedly so. It is a fine high-coloured sort and a sure cropper. Hunt's Tawny is, of course, an earlier, but otherwise not so good a Nectarine. It strikes us from what we have seen of Lord Napier that it must ultimately take a high position as an early Nectarine. It ripens about a fortnight before Hunt's Tawny, and is perhaps the largest Nectarine in existence; it is also excellent in quality; but how it will stand forcing from the end of November onwards through the winter has not, so far as we are aware, been yet well tested. As a midseason fruit it is one of the freest, and it is reasonable to suppose that it will also succeed for winter forcing.

In all seasons early ripening varieties of fruits are of much importance, and they have perhaps never been more so than this year, when early forcing has been found more of an uphill business than it has been for perhaps half a century.—*The Gardener.*

Peach Early Amsden.—This, brought on in a Vinery in which the Grapes are only fairly set, was quite ripe on the 17th of June, whereas Early Beatrice will require three or four days to finish properly; the latter, however, is much the larger and finer-looking of the two, the former being medium-sized, though high coloured.—T. SMITH, *Newry.*

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Effect of Frost on Vines.—The way in which frost destroys or injures vegetation is not fully understood, even by those who have made the subject one of special study; nor is this to be wondered at, considering the many instances that from time to time occur which appear inexplicable. One of the most remarkable which I recollect came recently under my notice in a market garden near one of the northern manufacturing towns. One of a number of Vineries was started so as to have the Grapes ripe in August. It was a large span-roofed structure, standing with its ends east and west, and contained eighteen Black Hamburgh Vines planted out on the south side, and introduced to the house in the ordinary way above the wall-plate; the stems were protected with thick straw ropes, as is generally done. A gutter under the eaves, too, carried off the roof-water

severed from the lower part. The Vines have been planted eighteen years, are very strong, and all along have borne heavy crops. The shoots this season, particularly on the injured ones, are extremely thick and stout, just such as might be expected from good Vines that had been cut back as far as the point to which these have been killed down, and had all their strength concentrated in the production of a limited number of shoots. I had an opportunity of examining these Vines closely, but failed to find the slightest clue to the reason why they have been thus partially killed back. Had they been killed right out, or down to the ground, the matter would have been intelligible; or had the upper part of the stems from the point where they entered the house been placed under dissimilar conditions, or the frost been able to reach them inside in any way, then there would have been little at all remarkable; but to see the tops, where wholly out of the reach of the frost, destroyed down to a certain point, and

Odontoglossum cirrhozum.

to a drain, which conveyed it away. The house was filled with bedding plants, and, as a matter of course, fires were kept in continuously to exclude the frost, which was effectually done, not so much as a leaf of these being injured. The Vines were pruned as soon as their leaves were off, and were allowed to remain slung up to the rafters right across the house, of which they occupied both sides of the span. The internal warmth, as usual in such cases, caused the ice and snow accumulated from time to time on the roof to melt and run down into the spout, which soon got full of ice, and, running over, the water fell on the straw-covered stems of the Vines, until the whole of those occupying the centre of the house were covered with a frozen sheet like a huge icicle. Nothing further was noticed. The frost went, the bedding plants were cleared out, and the Vines were started. Those at each end of the house that had escaped the icy coat broke, as usual, and those in the centre broke similarly to about half-way up the south side of the roof, some a little below that, others above, but beyond they are as dead as if they had been six months

the lower part as strong and vigorous as can be, is indeed a mystery. They were showing plenty of fruit. I understand that there is another similar case in the same neighbourhood.—P. G.

Stone Apple, or Loddington Seedling.—This excellent Apple, the original tree of which still stands in sight of my window, seems likely to maintain its good free bearing character this year, as although most kinds are bearing a thin crop, this is well set with fruit. I may mention that the name of Stone refers to the original occupier of the farm, and Loddington to the parish in which it grows.—J. Groom, *Linton*.

Mulching Strawberries.—This important operation in reference to Strawberry culture should be performed early in the season before the flower-stems get far advanced, as if deferred until the blossom is open, or, as is too often the case, until the fruit is formed, it cannot be so expeditiously or effectually performed. We usually take long litter from the stable to our Strawberry beds,

when it is spread evenly over the surface and then worked around the crowns by hand. If done in March or April, its manurial properties are gradually washed down by rains, and the straw is left clean and sweet for the fruit to rest on, keeping the soil moist and drying quickly after rain. I have tried many other kinds of material for this purpose, but have found nothing so satisfactory as stable litter.—J. GROOM, *Linton, near Maulstone.*

Wintering Strawberries in Pots.—In reference to the controversy as to the amount of care required by pot Strawberries in winter, I send you a runner which, after lying in a 2½-in. pot all the winter in frost, snow, and rain on a path, was placed about three months ago on the inside border of a cool Vinery, where it perfected good foliage and fruit. As an experiment I also repotted some roots of the same Strawberry, *La Grosse Suerce*, and *Sir C. Napier*, fruited last spring in a cool Vinery, and they yielded a second crop in October and November, and a third which has just been picked. I am very successful in the cultivation of Grapes, Strawberries, and Melons with humble appliances, the grand secret being "no coddling."—E. F. C., *Bath.*

Improved Quatre Saison Strawberry Duru.—This is one of the more recent and improved varieties of the season's Strawberry, which is so much grown in Continental gardens. It is to be

Improved Quatre Saison Strawberry Duru.

regretted the culture of these Strawberries is not more common here, as their flavour is good, and they continue in fruit if fairly well treated as long as the weather is at all favourable. It is offered by Messrs. Vilmorin, of Paris, and is said by them to be very fertile.

Fruit Prospects.—These become worse and worse. It seems as if the pollen had either been washed away by the rains which we daily experience, or been converted into an inert paste. Be that as it may, the fruits keep falling, falling until there are few or none left. Apples have fallen in showers; Plums in not a few cases are nearly all gone; and many Pears have also dropped. Pears, however, though flowering much earlier than Apples, have set better and keep their hold of the trees with far more tenacity. Cherries also promise to be a full crop, and those Gooseberries that escaped the spring frost seem to enjoy the constant downpours, and their fruits are swelling fast. Raspberries are also moisture-loving plants, and they show well. Strawberries, which were most promising, are failing fast, the flower and embryo fruits either dropping or rotting rapidly, till soon hardly a sound fruit will be left. This will prove a great disappointment, for hardly ever have Strawberries presented a finer prospect and forest of bloom over a fine spread of clean foliage. The better kinds of fruits on walls have also suffered much. Apricots are pushing in a wholesale way, and Peaches and Nectarines have suffered from severe attacks of curl and aphides. The fruit of both, too, are thin, though wall trees bloomed well and looked at one time unusually healthy.—D. T. FISH.

Peach Early Alexander.—If this Peach be as large and good as Mr. Rivers asserts it will be quite an acquisition and most valuable for early forcing. The Early Beatriceis, as Mr. Rivers states, too small, as well-grown specimens of it are not larger than small Nectarines or full-sized Walnuts, and to any one accustomed to see fine fruit, such pignies are not thought much of, and sorts producing them will only be cultivated for the sake of obtaining a dish or two before others, like the *Grosse Mignonne*, *Royal George*, &c., can be had in. As Peaches, like Vines, take some time to get into a bearing condition when they are planted permanently and trained to trellises, it is necessary to be particular what one buys, for it is very disappointing after waiting two or three years to find the variety introduced turns out comparatively worthless. It would appear, however, that there is no risk of this with the Early Alexander, and growers will therefore be on the look-out to add it to their collections.

I have found it a good plan where there are only two or three trees grown in one house to bud several sorts on them, by doing which a better succession of fruit may be secured, and any one having already such kinds as the *Beatrice*, *Early Rivers*, or *Hale's Early*, will find it advantageous to operate on them in the same manner, and as the *Alexander* progresses and is found more desirable the stock it is worked on can be cut away to make room. The budding of Peaches and Nectarines is a very simple affair, and is just as easy to carry out as that of a Rose, for if the bark will run properly and the bud is removed and put in without bruising the bark, it is sure to take and start away freely the following year. The trees and wood are just now in fit condition where they are under glass, and the work may therefore be carried out at once in their case, and a little later on with those on walls.—S. D.

GARDEN DESTROYERS.

THE COCKROACH OR BLACKBEETLE.

(*BLATTA ORIENTALIS.*)

THIS very common and widely distributed insect appears to be a nuisance wherever it is found. Few persons, if any, will say a good word in its favour. Many, indeed, have a sort of superstitious dread of these insects, which is probably caused by their very unattractive appearance, most unpleasant smell, and nocturnal habits. This species is not supposed to be indigenous in this country, but to have been introduced from some warmer climate; it has, however, been naturalised in our houses for many years. It is never found in this country except in warm situations, such as in dwelling-houses, hothouses, &c. In these it is sometimes found in very large numbers. In the former the amount of damage they commit is very small if proper care be taken to keep everything edible out of their way. This, however, is easier said than done, as they are almost omnivorous, and can creep through very narrow cracks. Still, the crumbs, &c., which they find on the kitchen floor are what they chiefly feed on. The cultivator is most annoyed by them in his stoves, Orchid houses, and Mushroom beds, where at times they are very destructive. The young fronds of Ferns are often attacked by them, and so much damaged that the appearance of the plants is quite spoilt. Orchids which have large fleshy aerial roots suffer very much from the cockroaches eating the young tips. When present in large numbers collections of Orchids have been very severely injured in this way, and, in consequence, have suffered much in health. Various other plants are at times attacked by them. In dwelling-houses cockroaches hide during the day near fireplaces, behind the skirting boards, in any crack or crevice which will afford them shelter. In greenhouses they will conceal themselves under large pots which have not been moved for some time, in cracks in the walls, particularly if they are in warm situations, near flues or hot-water pipes; and although such large insects when fully grown, will crawl into places which at first it would appear impossible for them to get into.

Many devices have been tried to keep this pest in check, most of which are efficacious to a certain extent, but none are certain to exterminate them; and while circumstances favourable to their mode of life and propagation still remain, it is almost useless to do so, as a fresh stock is sure sooner or later to occupy their places. The best chance of really ridding a hothouse of this pest is to reduce their numbers by traps and poison as much as possible, and then to fill up every crack and crevice where they could find shelter with cement, and to remove all pots and movable articles under which they could hide. In dwelling-houses care should be taken to fill up all cracks near kitchen ranges, &c.; to clear out all eupboards, and to leave nothing about, such as crumbs, &c., on which they can feed. If due care was taken by every one whose premises are infested by this insect, it would soon become a *rara avis* in this country. Among the many plans for destroying cockroaches suggested by various persons, the following are perhaps the best. The common traps sold in the shops are very good, but after a few days' use the beetles seem to avoid them; whether the traps get tainted by use in some way, or what the cause is, I cannot explain. A small basin half filled with beer or porter and sugar, or, if the cockroaches are teetotalers, honey and water or treacle, with small pieces of lath placed so that the insects can run up them from the ground to the rim of the basin, answers better than the traps, and the basin can be thoroughly cleaned and fresh pieces of lath used occasionally; gallipots sunk in the ground so that the rim is level with the surface, partly filled with one of the above-mentioned liquids, are very useful. Arsenic mixed with honey or boiled Potatoes or Oatmeal is much recommended as a very fatal bait. The heads of common matches dissolved in water and mixed with flour

and sugar, two boxes of matches to $1\frac{1}{2}$ pints of water, 1 lb. of flour, and $\frac{1}{2}$ lb. of sugar, Chase's beetle paste, Roth and Ringeson's beetle poison, and Hardiman's beetle powder, have been used by many cultivators with great success. All these poisons are best laid on small pieces of glass, glazed earthenware, or slate, for if placed on any absorbent substance these preparations soon become dry, in which state they are useless; but if kept moist they may be used two or three nights in succession. Care should always be taken that no cats or dogs should have access to the places where the poison is laid; it is always safer to remove the baits in the morning. Hedgehogs are often employed to destroy these insects, and are very useful when kept in kitchens for this purpose. Fronds of the common Brake (*Pteris aquilina*) are sometimes laid about near their haunts, which they are said to eat greedily, and to die soon afterwards from the effects. The cockroaches belong to the same Order (Orthoptera) as the grasshoppers, but they constitute quite a distinct family, and have nothing to do with beetles, though they are often called so by ignorant persons. Those species which are indigenous to this country are comparatively small, never infest houses, and are not known to be injurious to cultivated plants in any way. Some of the tropical

two broods of this insect during the year, although they may be found of all sizes at any time of the year. G. S. S.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE thirty-sixth anniversary festival of this institution was held on Wednesday evening last at the "Albion," Aldersgate Street, under the presidency of Mr. Serjeant Cox.

The usual loyal toasts having been given, the chairman proposed the toast of the evening, "The Gardeners' Royal Benevolent Institution; long may it prosper." He stated that the society had existed more than forty years, and that it began its career in a humble way with a very small party at its first dinner; it had, however, grown and grown till it had reached its present magnitude. That was, no doubt, because its objects were so excellent, for they were nothing less than making provision against misfortune that will come sometimes even upon the most prosperous without any fault of their own. The objects of the society were to enable those whom misfortune had visited to end their lives comfortably and without absolute penury. He observed that the provision made for males, £16 a year, was a very moderate sum indeed for nurserymen, seedsmen, gardeners, and growers who had fallen into distress, or for their widows or families. No object could be more admirable than that. There was no employment the active pursuit of which so much exposed a man to early illness as that of gardening, for he had to go from one atmosphere to another, from moist to dry, and there were many constitutions which could not endure it. The gardeners were of all persons the ones for whom provision should be made for times when distress might come upon them. It might be asked what service the society had actually done. He was himself anxious to know what it really had done, and the secretary had placed before him some of the cases in which charity had been exercised, and which will leave no doubt on any mind of the great uses to which these funds are devoted. One of the cases, he would say, was that of a gentleman who was himself a seedsmen and member of a flourishing firm, who commanded a very large income and lived in the highest state of respectability. He was also a subscriber for more than twenty years to the society; but misfortune came upon him and his partners and he became almost dependent upon the society. He is more than eighty years of age, and has to look for his support from the society. Another case was that of a gardener who had been in the service of a gentleman over forty-nine years. His employer told him that he had provided for him in his will, and that he should have an annuity of £100, but, owing to the will being disputed and set aside, the gardener was thrown upon his own resources, and would have almost starved, but for the help he had received from this society. These were objects the importance of which could not be exaggerated, and of which too much could not be asked for their support. In the first place he would appeal to the nurserymen themselves. From the list of subscribers he gathered that throughout the country they did not contribute to the society as they should do, and he would urge upon them that for their own interests they should become subscribers. Their managing men should also subscribe, and it was to their interest to do so. He would appeal also, and he hoped not unsuccessfully, to the "outsiders," the horticulturists of this country, the men who love gardening and follow it for pleasure and not for profit, the thousands who are making horticulture their great pursuit and pleasure, to assist by subscribing towards the funds of this society. As regards the nurserymen, he would ask them one and all, what would they do if it were not for collectors—men who went to all parts of the world, and sometimes at great risk, to collect rare and beautiful plants, &c., for the adornment of our gardens? They all knew the name of Veitch; he remembered the old Mr. Veitch when he lived in Exeter, and how he used to see him constantly at his place of business there. He was sorry to say the representative of the third generation was not among them, but he had received a letter from him, expressing his great regret at not being able to attend, but that his heart and soul were with them. He had forwarded them ten guineas. Mr. Veitch, Mr. Bull, and his old and much respected friend Mr. Williams, to each of these they were all deeply indebted. If all the nurserymen and growers and all the amateurs would subscribe, by-and-by the chairman would have the pleasure of announcing a pension something more than £16 a year.

Mr. Robert Wrench (the treasurer) responded to the toast. He hoped that as a result of the chairman's remarks their hearts would be touched, and that they would go out into the world and try to get others to contribute to the society. The great difficulty was that they could not get those who were most interested in it—the gardeners themselves—to do their part, although they were not at all slow in asking help in the time of their troubles. He hoped most

species are very large—one measures 6 in. across its wings when fully opened—and the damage caused by some of these insects is very considerable, as they will devour almost anything that comes in their way. An officer on one of Her Majesty's ships on the Australian station told me that a harmonium on board was entirely destroyed by them, only the case and metal work remaining; his clothes, books, and papers were also much injured. Cockroaches undergo the same number of transformations as other insects; but when in the larva (caterpillar) and pupa (chrysalis) states differ very much from most insects, as in both states they much resemble their parents, and the pupae, instead of being in a quiescent condition, are just as active as the perfect insects. The female, instead of laying her eggs singly, deposits them altogether, surrounded by a horny case, in some convenient place. This case is often carried about by the female, for some days protruding from her body; it is somewhat the shape of a bean, and is not quite $\frac{1}{2}$ in. long, and has a longitudinal slit along one edge which is rather compressed; the lips of the slit are serrated and cemented together. The eggs within are placed separately in two rows of chambers, and are usually sixteen in number. When the young are hatched they discharge a fluid from their mouths, which dissolves the cement at the slit, and the young are able to push their way out. At first the young are whitish, but they soon become darker, and are very similar in appearance and habit to the perfect insect, but are smaller and entirely without wings. They change their skins five times within about three months; after their fifth moult they are in the proper state; the thorax is now fully developed, and the rudiments of wings are apparent; in about a month the skins are cast for the last time and the insects are in their perfect condition. The cockroach is dark brownish-black, very shining, about 1 in. long, and much flattened. The head is furnished with a pair of very long, hair-like antennae, consisting of a great number of very small joints. The mouth is provided with a pair of strong toothed jaws; the thorax is roundish, the width rather greater than the length, flat, with the central portion somewhat raised. The legs are long, flattened, and armed with strong spines. The joints of the body are very well defined, and from between the last two there proceeds a pair of shortish many-jointed organs, the use of which is uncertain. The males may easily be distinguished from the females by their larger wings. In the former they are long, the upper pair being rather horny, and forming a covering for the lower when at rest. The female has only the rudiments of wing-cases and no lower wings. There are only

sincerely that what he had said would have some little effect upon them. The loss of a small amount of 6d., slipped in a box each week, would not be felt, and would more than make up the guinea subscription.

Mr. Rudkin, C.C., proposed "The Health of the Chairman." This was a pleasing task, because their friend had pleaded to them so eloquently, and he believed the result would be a large subscription. There was no doubt that at gatherings of the kind it was desirable to have a gentleman occupying the chair who thoroughly appreciated the position he was in. He believed the chairman was a great lover of flowers, and he was given to understand that he was one of those who thoroughly patronised this institution.

The chairman thanked them for the kind expressions of their regard. He felt a great interest in the society, for he had been an ardent lover of horticulture from early youth, and still paid much personal attention to his garden.

Mr. Brandreth Gibbs, in proposing "The Health of the Secretary," said that their secretary was undoubtedly a sympathetic man, and had always got the interests of the institution at heart; therefore it afforded him very great pleasure to be there, and to ask those present to show how highly they appreciated his long and valued services. The toast having been drunk with great cordiality,

The secretary rose and said that the list of subscriptions which he held in his hand was a very long one, and amounted to a large sum; indeed, the subscriptions had come in much better than he had anticipated. The list was too long to read to them, but amongst the names were the two firms of Messrs. Dicksons, of Chester, one of which contributed 43 guineas and the other 40 guineas. The Duke of Westminster had also forwarded them 5 guineas, which would be continued yearly. Then their worthy chairman had brought over 70 guineas, and last, but not least, their old friend Mr. John Fraser had sent 100 guineas, while the total amount of subscriptions amounted to 500 guineas. Many years ago, in the early days of the institution, they could only manage to get about thirty-five people to their dinner, and when the subscriptions amounted to about £60 it was thought very good indeed. He regretted to say that there were at the present time but three gentlemen living who were the society's supporters in its early days; they were Mr. Sangster, Mr. John Lee, and himself. In conclusion, he hoped to serve in the future, as he had done in the past, to the best of his ability.

The "Health of the Treasurer" having been proposed by the chairman and responded to,

Mr. Shirley Hibberd proposed "Success to the Royal Horticultural and Royal Botanic Societies of Great Britain," and in the course of his remarks said that the smaller societies helped in a very considerable degree the domestic life of this country. The great societies in other large towns, too, were promoting the interests of horticulture in a special manner. They collected and diffused useful information, and they maintained the standard of taste, which was a matter of the utmost importance. With regard to the commercial depression, it did not appear to him to have affected gardening much, for both gardeners and gardens still continued to increase and multiply. Their gardens no doubt enabled them to bear the dulness of the British winter, therefore the art of gardening should be encouraged by all the powers they possess; and all that belonged to gardening should most certainly have their sympathy.

The chairman next proposed "Success to the Seed Trade," coupled with the names of Messrs. F. Arthur Dickson and B. S. Williams, both of these gentlemen responding in suitable terms.

SOCIETIES AND EXHIBITIONS.

NATIONAL ROSE SOCIETY'S EXHIBITION.

JUNE 28.

THIS exhibition, which took place at the Crystal Palace on Saturday last, was, owing to the backwardness of the season, much inferior to those held on other occasions, both in point of numbers and quality of the exhibits. This will be apparent when we mention that not a single Rose came from the Cheshunt, Waltham Cross, Slough, or King's Acre Nurseries; neither were the most prominent of the amateur growers well represented. There was, therefore, a large amount of unoccupied space. In the nurserymen's class for seventy-two single trusses Messrs. Curtis, Sandford, & Co. were first with a fairly representative collection, amongst which were magnificent blooms of Mlle. Eugénie Verdier, the delicate-tinted La France and Rubens, fine blooms of the brilliant Duke of Edinburgh, Exposition de Brie, Sénateur Vaisse, Mons. Fillion, Victor Verdier, Eugène Appert, Prince de Rohan, and others. The other competitor in this class was Mr. H. May, The Hope Nurseries, Bedale. The best forty-eight trusses of threes were shown

by Messrs. Keynes & Co., Salisbury, and comprised fine examples of John Hopper, Eugène Appert, Miss Hassard, La France, John Fraser, Exposition de Brie, and others. The next best collection was contributed by Mr. May, the crowded arrangement of whose stands was a remarkable contrast to the thinly-disposed stands in the preceding collection. Messrs. Kinnmount & Kidd, Canterbury, had some splendid blooms in their first prize collection of thirty-six single trusses, amongst the finest of which were Baroness Rothschild, Madame Lacharme, Duke of Edinburgh, Annie Laxton, Cheshunt Hybrid, Abbé Brammerel, Dupuy-Jamain, Baronne Haussman, Julie Touvais, and John Hopper. The others in order of merit were Mr. W. Corp and Mr. W. Piper. For twenty-four varieties in trusses of three the exhibits were inferior, and the first prize was accordingly withheld. Messrs. J. Mitchell & Sons, Uckfield, were first with twelve Tea or Noisette varieties, the best of which were—Maréchal Niel, Comtesse Ouvaroff, Jean Pernet, and Moiret. The classes for amateurs were more numerous represented, though the Challenge Cup for forty-eight single blooms brought out no competitors. The best thirty-six blooms came from Mr. J. Hollingworth, and comprised fine examples of Marie Baumann, Victor Verdier, Sultan of Zanzibar, Charles Lefebvre, Duke of Edinburgh, Adam, Beauty of Waltham, and Madame Willermoz. Mr. T. Jowitt showed some fine blooms in the next class, amongst which Niphetos was particularly noteworthy. There were six other contributors in this class. Collections of nine blooms were numerous, and comprised some remarkably fine examples, especially those from the Rev. H. Biron, who gained the highest award. Rose Maréchal Niel was shown in excellent condition by Mr. J. Davis. Messrs. Curtis, Sandford, & Co. were the only exhibitors of twelve blooms of Abbé Carrière, and the classes for trusses of Marie Rady, Reynolds Hole, and Marquise de Castellane were totally unrepresented. The best dozen blooms of any Tea or Noisette variety were shown by Mr. N. Farren, Cambridge; the old Souvenir d'un Ami was the kind exhibited, and they were in very fine condition. The next best dozen consisted also of the same variety. The beautiful Cheshunt Hybrid was also shown in this class, to which the third prize was awarded. New Roses were exhibited by Messrs. Curtis, Sandford, & Co., and comprised the following: Madame W. Bull, Penelope Mayo, Mabel Morrison, Catherine Bell, Madame Gabriel Luizet, Mrs. Baker, Duchesse d'Ossuna, Mons. Fillion, Souvenir d'Adolphe Thiers, Madame Berthe de Montchauveau, and Mons. Michel Dupré. Several collections not for competition were exhibited, the principal of which being from Mr. W. Corp, Oxford; Mr. Prince, Oxford; Mr. C. Davies, Aynhoe; and Mr. Tranter.

Miscellaneous.—A choice group of plants was contributed by Messrs. Laing & Co., Forest Hill, consisting of fine examples of tuberous-rooted Begonias in rich variety, Palms, Dracænas, Crotons, and Caladiums, the whole effectively arranged, and adding much to the attractiveness of the show. Cut blooms of Pansies, Pyrethrums, and Ranunculi were sent by Mr. H. Hooper, Bath; and Mr. Cannell, Swanley, showed a numerous collection of cut blooms of Pelargoniums in numerous varieties. Mr. Ware, Tottenham, also sent a collection of Pyrethrum blooms. Mr. Boller contributed an interesting collection of Agaves, Cacti, &c.; and Messrs. Dick Radclyffe & Co. their elegant statuette fountain tastefully surrounded by Ferns, &c.

A list of awards for this and the following show will be found in our advertising columns.

ROYAL BOTANIC SOCIETY.

EVENING FÊTE, JULY 2.

THE floral decorations at the annual evening entertainment held on Wednesday last formed an important feature, and on the whole were more numerous than we have noticed on previous occasions. The table decorations were much admired for their tasteful and neat arrangement, especially those in the unfurnished class, the best in which was arranged by Mrs. Guimarães, Reigate, and consisted of Grasses, Rhodanthé, Ferns, and Selaginella, and delicate blush-coloured blossoms of Pæony. For the best arranged tables in the furnished class, Messrs. Mortlock & Sons and Mr. W. Soder were awarded equal first prizes; in the former arrangement fruits formed a conspicuous item, and in the latter the common white Water Lily blooms, which admirably contrasted with the crimson flowers of *Cercus speciosissimus*. Messrs. E. G. Henderson & Sons' exhibits were very tastefully arranged, and were accorded the highest rank in their respective classes. The arrangement for a recess or alcove was much admired; the principal plants used were *Eulalia japonica zebrina*, *Cocos Weddelliana*, *Adiantum gracillimum*, *Anthurium Scherzerianum*, and the pretty *Impatiens Jerdoniae*, which shows to such advantage by gaslight. The same firm also exhibited an arrangement suitable for an outside recess, in which the chief

plants used were *Todea superba* intermixed with the brilliant *Hemantthus coccinea*, and *Odontoglossum vexillarium* with a background of Palms; whilst above were suspended numerous *Dendrobiums*, *Oncidiums*, and other Orchids in flower. The designs exhibited by Messrs. Dick Radclyffe and Co. were very numerous and of superior merit, and in all of them a conspicuous feature was that the plants employed were more of the hardy or greenhouse class, hence more suitable for decorating balconies, window recesses, &c., than valuable tropical exotics, and the effect produced is scarcely inferior. The exhibits in the classes for *epergne* and vase decoration were numerous, as were also those for bouquets, &c. The best hanging basket was shown by Messrs. Henderson and Sons; it consisted of *Davallia dissecta* growing naturally on the outside with the showy *Anthurium Scherzerianum* in the centre.

In the miscellaneous classes the pretty statuette fountain shown by Messrs. Dick Radclyffe and Co. formed a pleasing feature; as did also the elaborate indoor aquarium exhibited by Mr. Langbein, Wandsworth Road, to which an extra prize was awarded. Messrs. Carter and Co.'s display of annuals in the corridor had a very bright appearance by gaslight, and were the admiration of everyone. Mr. Anthony Waterer's exhibition of *Rhododendrons*, too, was well lighted, and the varied hues of these gorgeous shrubs produced a brilliant effect.

SCOTTISH PANSY SOCIETY.

RARELY has this Society's show been held under more unpromising auspices than those which attended its thirty-fifth annual competition on 27th ult. at Edinburgh. The past season has been one of the worst on record for the successful cultivation of Pansies, while the ten days previous to the show were wet, with very little sun to bring out the blooms. In spite of these drawbacks, however, the display was not greatly inferior to that of last year, which was pronounced to be the best and largest ever made by the Society. Indeed, on the present occasion the cases entered for competition numbered 160, against eighty or ninety last season—the result of fresh accessions to the membership. As in former years, Pansies for competition were forwarded from many parts of Scotland, while a box of fine fancy blooms was sent for exhibition by Capt. Halford Thompson, Hon. Sec. of the West of England Pansy Society, Exeter. These blooms suffered a little in transit, but they were good flowers, and nearly all north-raised varieties, illustrating the fact that Scotch Pansies can be as successfully cultivated in the south of England as in Scotland.

In the nurserymen's class for twenty-four blooms of show Pansies, Mr. Paul, of Paisley (for the fourth successive year), was awarded the first prize and the Society's silver medal, with fine flowers of *Cyprus*, Rev. J. Morrison, J. P. Barbour, Sir Peter Coats, Michael Saunders, Alex Watt, dark self; Mrs. Goodall (seedling), *Improvement* (seedling), white self; *Golden Queen*, *Golden Circle* (seedling), yellow self; the other flowers being seedling yellow and white grounds. Second, Messrs. Jas. Cocker & Sons, Aberdeen; third, Messrs. Dickson & Co., Edinburgh.

For twenty-four fancy Pansies, Messrs. Downie & Laird, Edinburgh, received first prize and silver medal with the following varieties: Mrs. S. Plummer, Angus McLeod, Hon. Mrs. Bentson, Jas. Grieve, Wm. Melville, Lady Falmouth, Countess of Home (an extra fine flower of immense size), Miss Talbot, Mrs. Crawley, Miss McMeeking, Miss McNut, Jas. Crave, Countess of Strathmore, Mrs. L. T. Fleming, Sir P. K. Murray, Lady Hay, Mrs. E. H. Wood, Mrs. Longfield, *Adonis*, and five seedlings; second, Mr. Paul, Paisley, with *Thalia*, *Rosamond*, Mrs. Hubbard, Thos. Grainger, J. Clark, *Champion*, J. B. Downie, F. W. Leland, Mrs. Birkmyre, *May Queen*, *Captain Thompson*, Mrs. Robinson, *Captain Tomlin*, Mrs. Jamieson, *Duchess of Edinburgh*, *Rose Charlton*, Wm. Melville, *Adonis*, *Monarch*, Angus McLeod, Mrs. James Watt, *Seedling No. 17*, Mrs. H. Dickson, Mrs. W. O. McCormick; third, Messrs. J. Cocker & Sons.

In the open class Mr. Paul carried off first for eighteen show Pansies with J. P. Barbour, *Cyprus*, *Mauve Queen*, Rev. J. Morrison (dark self), Mrs. Goodall (seedling, white self), *Golden Circle* (seedling, yellow self), *Florence*, *Minnie*, *Jeannie Grieve*, *Eurydice*, *Mary Paul*, *Lizzie Goudie* (white grounds), James Orr, *Clonard*, John Saunders, and three seedling yellow grounds.

Messrs. Downie & Laird were first for twelve bunches bedding *Violas* and twenty-four bunches *Violas*; Messrs. Dicksons & Co. second.

Messrs. Dicksons & Co. first, and Messrs. Downie & Laird second, for twenty-four bunches of bedding Pansies (excluding fancies). The bedding *Violas* and Pansies attracted much attention by their bright and varied colours. For three blooms dark self Pansy J. P. Barbour, Mr. Paul was first, also with three blooms fancy Pansy *Attraction*. Twenty-four self Pansies, viz., four blue, six

white, six yellow, and eight dark—first, Mr. Paul, with *Sunnypark Rival*, *Crossflat Rival*, *Royal Blue*, *Bluestone*, *Blues*; Mrs. Goodall, *Improvement*, *Miss Ramsay*, *Purity*, *Bessie Peacock*, *May Queen*, whites; *Golden Queen*, *Golden Circle*, *Cloth of Gold*, *Citron*, *Zama*, Dr. Masters, yellow; J. P. Barbour, *Cyprus*, *Dean's Glen*, *Oceola*, Michael Saunders, Rob Roy, W. S. Andrews, Walter Shearer, darks. Best black self (shown separately)—first, Mr. Paul, with James Dalziel. Best white ground in the exhibition, Mr. Kidd, *Rothsay*, with Miss Ritchie (seedling). Best yellow ground, Mr. Barr, *Paisley*, with Dr. Geo. Robertson (seedling). Best dark self, Mr. Paul, with J. P. Barbour. Best white self, Mr. Paul, with Mrs. Goodall (seedling). Best yellow self, Mr. Paul, with *Golden Circle* (seedling). Best blue self, Mr. Ross, *Laureneekirk*, with *Sunnypark Rival*. Best flower in the exhibition, Mr. Paul, with J. P. Barbour. Mr. Borrowman, Beeslack, gained the medal given to the winner of the greatest number of prizes, he having five firsts, six seconds, and one third; Mr. Paul being second with ten firsts and one second.

It is unnecessary to give the other prizes in detail. The gardeners' class was well represented by Mr. Borrowman, Mr. Forbes, Paisley; Mr. Airdrie, *Campbeltown*; and Mr. M'Cosh, *Montrose*; while in the amateurs' class, Messrs. Ross, *Laureneekirk*; Goodwin, *Malcolm*, *Kirkintilloch*; Barr, Paisley; Kidd, *Thomson*, *Rothsay*; Fleming, *Berwick*; Storrie, *Lenzie*; and Skinner, *Pennicuik*, showed, in excellent form.

THE EXHIBITION OF THE NEW YORK HORTICULTURAL SOCIETY.

THE annual summer exhibition of this Society was held in New York City on the 11th, 12th, and 13th of June. It may be remarked that this association holds a somewhat similar position here to that held by the Royal Horticultural Society in London, perhaps, and hence its successive meetings are always looked forward to with much interest by all lovers of the garden. The choicest varieties and the most remarkable specimens usually find their way to its handsomely-arranged tables, which are visited by practical amateurs and the *élite* of the garden art. The present display was held in Madison Square Garden, better known as Gilmore's Garden, a building eminently adapted for the purpose. In general extent and abundance the exhibition was perhaps somewhat less full than on previous occasions, but this was fully made up in the merit and superiority of the collection. The display of Orchids comprised the finest collection ever brought together here; over 100 specimens of the rarest varieties were shown, many of them exhibiting much skill in their culture. Among them I might name the *Odontoglossums*, a delicate white *O. vexillarium*, valued at 200 dollars; several species of the *Cattleyas*; *Dendrobiums*, *Aerides odoratum*, and the *Lælia autumnalis*. Mr. Buchanan's group of *Agaves* and *Palms* was also a most attractive exhibit. Mr. Roenbeck, the great Fernist of New Jersey, contributed a very handsome and most interesting collection of these Cryptogamic plants, embracing some fifty varieties from broad, arched Tree Ferns to the delicate Maiden-hairs. He has succeeded in raising some fine seedlings of the latter class. There was also a very fine display of stove and greenhouse plants, many of which were grouped and arranged with excellent taste, and embraced fine specimens of *Cypripediums*, *Marantas*, and *Alocasias*; also a few plants of *Curmeria picta*. Mr. J. S. Bush's collection contained a fine variety of *Crotons* and some pretty *Draacenas*. The display of bedding plants was large and choice. Messrs. Woolson & Co., of New Jersey, had a unique arrangement of cut flowers from their hardy perennials and shrubs which attracted much attention, including *Rosa rugosa*, *Viburnum plicatum*, and the charming native Orchid *Cypripedium spectabile*, and *Gillenia trifoliata*. There were, however, less cut flowers than usual, but those shown were in most cases prettily disposed in handsome natural groups, and the huge uncouth "floral designs" were largely omitted. The display of *Roses* was very fine, and many choice varieties were shown evincing careful culture. The leading American novelty in this class was the American *Banner Rose*, recently produced and shown by Mr. Peter Henderson. In it the colour and details of the national emblem are partially reproduced, and it formed an object of considerable interest. Its production is a somewhat marvellous freak. Some of the *Jaqueminot* blooms were exceptionally perfect. Messrs. Parsons & Sons had an excellent collection of evergreens and Conifers, for which they have long been celebrated, and the grouping of their exhibits was happily effected. Some of the newer varieties are specially attractive in colour, form, and habit. Their show of deciduous trees and shrubs, and the new Japanese Maples was also a most interesting feature of the exhibition.

The tables devoted to the display of fruit, owing to the earliness of the season, were not large, and mainly contained *Strawberries*, of which there was a smaller variety than might have been shown a week later. However, some very fine specimens were shown, and

the wonderful progress that has been made in this country of late years in the culture and improvement of this most luscious and wholesome fruit was amply indicated. E. P. Roe, of the lower Hudson valley, took the prize for the best collection, which contained some very handsome fruit. His specimens of the President Lincoln variety were quite remarkable. This is now the largest kind grown in this country, and in other ways most promising, as I can fully testify, having specimens in my garden now measuring from 7 in. to 10 in. in circumference, with an excellent flavour. Of this and other new American varieties I shall, if all goes on rightly, speak more in detail in a future number of THE GARDEN. Mr. Peter Henderson also exhibited some fine specimens of this fruit, and took a number of prizes for special varieties. The meeting was most successful, it being very largely attended.

H. HENDRICKS.

Kingston, N. Y.

Richmond Horticultural Society.—The recent annual summer exhibition of this society, held the other day in the old Deer Park, was in all respects a great success. The grand groups of plants sent by the leading London nurserymen were objects of close attention, and hundreds clustered round the pans of tiny Sundews and Fly-traps, so-called carnivorous plants, which but for the protecting bell-glasses might have been subjected to rather too severe treatment. Messrs. Veitch and Sons had Orchids, Nepenthes, Lady's Slippers, Begonias, and many rare plants, a beautiful group; and fixed into a pot, a branch, literally a mass of snowballs, of the hardy Viburnum plicatum. Mr. John Wills also had a fine group, that included many fine Dracænas and beautiful Gloxinias. Mr. B. S. Williams had huge pitchers that excited the wonder and admiration of the spectators. Mr. Boller put up one of his curious groups of Cacti, which included a *Pilocereus senilis*, the White-haired Old Man, and another hard metal-like specimen, each fifty years old. There also was a quantity of the diminutive forms for which Mr. Boller is famous. Messrs. Osborn and Sons had not only groups of indoor plants, but also a pretty and very interesting collection of hardy perennials. Of table decorations, which now form an important element in household floriculture, there were numerous examples. The prizes offered for model gardens brought forth some singular illustrations, rather to be avoided than imitated; whereas models of real gardens with the actual garden specified would be really instructive. In the groups of plants arranged for effect on the ground the art capacities of the gardener was to some extent brought into play. The group arranged by Mr. James Hudson, gardener to T. S. Atkinson, Esq., of Gunnersbury, was in every way admirable.

Daniels' Defiance Cabbage Competition.—Messrs. Daniels, Norwich, offered some time ago several money prizes for the heaviest and best three specimens of the Defiance Giant Cabbage grown from seed supplied by them, and for the prizes there was a spirited contest on Wednesday last. Specimens were sent by over a hundred growers, and many of them were remarkable, not only for size, but quality. It will be seen from the prize list that the premier exhibits came from the Isle of Wight, and others from various districts. There were numerous competitors in Norfolk, but their specimens, though fairly well grown, were small compared with those of the prize winners. The following is the prize list: First prize, £10. Mr. S. Osborne, Old Park, Ventnor, Isle of Wight, weight 36 lb. 8 oz. Second prize, £7. Mr. T. Creed, Kemsdale, Faversham, Kent, weight 35 lb. 14 oz. Third prize, £4. Mr. E. Pitts, Mirables, near Ventnor, Isle of Wight, weight 35 lb. 12 oz. Fourth prize, £2 10s., Mr. E. Samuel, Sawston, Cambs, weight 34 lb. 14 oz. Fifth prize, £1 10s., Mr. E. Nunn, Heybridge, Maldon, Essex, weight 33 lb. 4 oz.

Lime Water and Slugs.—It seems to be a general opinion that slugs are more abundant this year than has ever been known, and it appears very extraordinary that no writer on the subject has yet said a word respecting the most effectual remedy for them, viz., lime water. Hot lime is constantly recommended, but if any one will watch the process of throwing hot lime over the ground or the plants infested by slugs it will be seen how numerous are the spots and spaces which the lime does not cover, and how utterly impossible it is for the most skilful sprinkler of hot lime to apply it effectually all over a leafy plant. If those interested in the destruction of slugs will take the trouble to mix hot lime and water together, and after well stirring it let it stand until all the lime has settled at the bottom, and then use the water in the evening with a watering pot with a good rose, they will be astonished and delighted to find in morning hundreds, if not thousands, of dead slugs, some of them as small as the top of a pin, which the lime water thus applied has killed on the leaves and about the plants where the powdered lime would never have reached them. It is not my intention to

depreciate the value of the application of dry lime, but it only does half the work, and I strongly recommend, from experience, watering with lime water as the most effectual remedy for slugs as well as using dry lime earlier in the day. The watering should be applied the last thing wherever there is danger of the sun striking on the plants or flowers.—A.

ANSWERS TO CORRESPONDENTS.

Strawberry Fungus.—S.—The plant sent is suffering from an uncommonly bad attack of the fungus named *Spumaria alba*. In a young state this fungus is like masses of thick white froth of various sizes. It is more common on Grasses than on other plants, and when young, as Berkeley states, it "might easily be supposed to be of animal origin."

Names of Plants.—G. J.—*Scilla campanulata*. W. S.—*Inga pulcherrima*. G. R.—Variety of *Ranunculus asiaticus* fl. pl. J. M.—Not an uncommon occurrence; the deep purple-coloured flower is *Cytisus purpureus*, the lighter-coloured kind C. Aitani; and the other the common *Laburnum*, C. *Laburnum*. F. B.—2, *Amelanchier canadensis*; 3, *Acer platanoides*. Gardner.—Varieties of *Azalea pontica*. W. A. B.—1, *Polygonatum multiflorum*; 2, *Muscari monstrosum*; 3, *Potentilla*—cannot name species without lower leaves; 4, *Tovaria racemosa*.—G. B.—*Solanum jasminoides*. G. B., *Farmaster*.—*Jamesia americana*. T. A. M.—2, *Iris florentina*; 5, *I. lurida*; 7, *I. variegata*; 8, *I. Pseud-acorus*; all the others are varieties of the above and *I. germanica*, which we cannot undertake to name. Major-General.—1, *Adiantum cuneatum*; 2, *A. Capillus-Veneris* (west of Ireland form); 3, *A. scutum*; 4, *A. venustum*; 5, *Athyrium Filix-Femina*. H. T.—4, *Acropera Hodgkisi*; 1, apparently *Oncidium divaricatum*; the other *Oncidium* we cannot name, as the specimens are insufficient.

Rosa Camellia.—Some time ago Capt. Thomas asked for information respecting this Rose. *Rosa Camellia* (Siebold) is not *rugosa* or *Regeliana*, but rather a variety of the *Rosa sinica* (Aiton), a climbing kind very common over a large part of temperate Asia, as well as in South America, to which Michaux believes it to be indigenous, and described it under the name *levigata*. It has also been described by Dr. Lindley and M. de Candolle under the name of *R. nivea*, and by another French botanist under the name of *R. Cherokeeensis*. It is only half-hardy at Segrez, suffering in severe winters. It belongs, I think, to the section of the Banksian Roses.

Wall Plants.—Could you recommend me a few plants not generally grown out-of-doors to try against a 10-ft. south wall with a good 8-ft. border?—R. H. Torquay. (Try *Lapageria rosea* and *alba*, *Solanum jasminoides*, *Akebia quinata*, *Halimifolia latifolia*, *Rhynchospermum jasmoides*, *Choisya ternata*, *Piptanthus nepalensis*, *Convolvulus Cneorum*, *Mutisia decurrens*, *Billardiera longifolia*, *Cantua dependens*, *Berberidopsis corallina*, *Plumbago capensis*, *Tecoma grandiflora*, *Clematis indivisa*, *Melianthus major*, *Medicago arborea*, *Cleistanthus puniceus*, *Lonicera sempervivens*, *Mandevilla suaveolens*, *Indigofera decora*, *Magnolia fusca*, *Embotrium coccineum*, and *Fremontia californica*.)

Bananas.—We have several *Banana* plants here which refuse to fruit, but which continue to grow most luxuriantly, the stems being 2 ft. in circumference and about 9 ft. high. They were taken off an old plant as suckers in the spring of 1878, and grown on throughout the summer. By the end of the season they were good plants in large boxes, and we wintered them in a minimum temperature of from 45° to 50°. From previous years' experience I fully expected them to fruit this spring, but they have not done so. What should I do in order to induce them to fruit, as it is of great importance to me to have the fruit well advanced towards ripeness before winter sets in?—ENQUIRER. [If the height, 9 ft., includes the leaves as well as the stems, I should say that the plants are not yet large enough to fruit. I measured one to-day and found it about the same height, with a stem over 2 ft. in circumference, and from its appearance I should think it will not fruit for five or six months yet. I never wintered any in so low a temperature as that just quoted, and should think that want of warmth is the cause of their being so long in attaining the size named. If planted out, as ours are, and grown in a high temperature, they would most likely have shown signs of fruiting early in the spring.—GEORGE SAGE, Ashridge.]

Celery all the Year Round.—Can any of your readers say whether it is possible to rear a succession of Celery all the year round, and how? (Celery stewed is stated to be an almost certain cure for rheumatism if taken daily for a long period; hence my question.—H. C. [It is possible to have Celery all the year round. Sow the first crop in January in a hotbed or in a hothouse near the glass. The plants, when large enough, must be pricked out in another hotbed, or they may be potted singly in small pots and grown on carefully without check, potting them into larger pots as they require it, and keeping them near the glass. In April plant them out under handlights on a prepared bed, three plants under each light. Earth them up by raising the soil in a cone-shaped mound round them. A strip of paper should be tied loosely round each plant before the earth is added. Another pinch of seed may be sown in February, and the main crop in March. Both sowings should be made in gentle heat under glass. Sow in the open air in April and again in May. Celery being a biennial under ordinary culture, the May-sown plants will not "bolt" till late in the blooming year.—E. H.]

Questions.

Olea fragrans.—Can any of your readers inform me if *Olea fragrans* is hardy enough to bear our winter planted out-of-doors? We are about 16 miles south of London, and 600 ft. above the level of the sea.—G. M.

Potato Failure.—Last year I planted Irish Green Top Rock Potatoes very early, and they were taken up before they were attacked by the disease, and a capital crop they were; some I have now are quite sound and well. We planted again seed from last year's crop early this spring, but many of them have rotted in the ground, and the rest are poor and weak in growth. The ground is stiff loam and well manured. Can any reader of THE GARDEN explain the cause of this failure?—R. G.

Mr. Hoskyns, late of Onslow, Shrewsbury, has been appointed gardener to George Wilder, Esq., Stanstead Park, Emsworth, Hants; and Mr. Crane, late of Huddlow Castle, Kent, has gone to Lord Sackville, Knole Park, Sevenoaks.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE COLLEGE BOTANIC GARDENS, DUBLIN.

We have great pleasure in announcing that Mr. F. W. Burbidge has been appointed curator of the University Botanic Gardens at Dublin. All who know Mr. Burbidge will feel that in this case a very important appointment, and one not very easy to fill with the right sort of man, has been bestowed, as it should be, upon the candidate most fitted for it. Mr. Burbidge's tastes and training have been exactly of the kind to fit him for the accumulation and preservation of such collections of plants from all regions as ought to be represented in any botanic garden worthy of the name. The College Garden at Dublin is one of the most interesting that we know of, and quite distinct in plan and contents. What its charm consists in we cannot define, but we have experienced feelings of pleasure in all that concerns plants there such as we have never experienced in any other garden, which may, perhaps, seem a very odd statement to make. Situated not far from one of the lower shores of Dublin Bay, the soil is very deep and sandy, and on this most herbaceous plants succeed as one seldom sees them anywhere else; and there is a very interesting and full collection of trees and shrubs and hot-house plants. Not the least remarkable, however, are the high and massive walls, everywhere covered, and well covered too, with interesting climbers or shrubs. Ireland is the country of ugly dead walls, but the garden walls here may be called beautiful, and they partly explain the peculiar charm of the garden. The college gardens were for many years under the superintendence of Mr. John Bain, who retired a few years ago through ill health. Mr. Bain was, as regards all cultivated and British plants, an acute and excellent botanist; while as a cultivator of the subjects thought most precious in botanic gardens and good collections, whether these were delicate Alpines or curious Fly-catchers, or Orchids, or rare medicinal plants, he never had a superior, so far as we have seen, in the public gardens of Europe. He was succeeded by Mr. F. Moore (son of Dr. Moore), who was most energetic and successful while he retained the curatorship, which he resigned on being appointed to Glasnevin. In the face of the tendency which has recently been manifested in certain important gardens to appoint men as curators who have had no training but that which fits them for ordinary private places, it is gratifying to see that a man well acquainted with both tender and hardy plants, and, moreover, familiar with their culture, has been appointed to a charge so important, not only as regards Trinity College, but the horticulture of Ireland, and the United Kingdom generally.

THE FUTURE OF OUR BOTANIC GARDENS.

FROM the numerous recent deaths among the curators of our great botanic gardens, and other changes that have taken place and are, we learn, about to take place therein, one is led to think somewhat more than usual of the difficulties under which botanic gardens are generally managed, and to point out the true way of managing them. Our own opinion, more than once expressed, is that all gardens should be managed by thoroughly trained curators, and that anything else is a source of weakness and of evil to the gardens. What we mean by a good curator is illustrated by the late James M'Nab, of Edinburgh, and the late Dr. Moore, of Dublin, not to mention living examples. Dr. Moore might indeed be taken as a type of a good curator of a botanic garden, and he was also, as is well known, a very good botanist. But he was a thorough curator of a garden, not because he was a good botanist, but because before and above the

botanist's knowledge was that acquired from early youth as a cultivator and observer in gardens. With an ordinary amount of study and the exceptional opportunities of a botanic garden, the acquirement of full botanic knowledge is not unfrequent in such cases.

It is not with any but feelings of great respect to the professors and science of botany that we have to say so much in the interests of horticulture—that the botanist's true field of labour is the Herbarium in which to store his treasures, and books in which to make his knowledge still more accessible. The least desirable in such a case is the appointment of a mere cultivator to a botanic garden—a man knowing but a few branches of the profession—in other words, say a first-class nobleman's gardener; for the management of a botanic garden requires great and varied knowledge of plants, quite different from that usually possessed by the private gardener, and the training amongst and often a love for old types of vegetation that never come within the knowledge of the ordinary-trained gardener at all. Skill in cultivating a few families of plants is no guarantee whatever that the cultivator is in any way fit for the management of a botanic garden. What is wanted in the last case is not cultivating and preserving the common things that everybody knows and grows, but in preserving and introducing the rare or the little-known types, to which we look for so much of the interest and beauty of our gardens; therefore, when we hear of a proposition to appoint at Glasnevin, which has hitherto been managed well by Dr. Moore, a scientific director and a curator, it seems to us that this would not be the best plan in the interest of the garden, inasmuch as it would very much increase expenditure without increasing efficiency. It would cause a division of authority in the garden, which would be most prejudicial to its interests. There may, no doubt, be a great difficulty in securing a man that would possess the essential qualification as curator, and at the same time be fitted from a social and educational point of view to take his place at the head of such an establishment; but this difficulty has been got over before and should be again, such men as David Moore, James M'Nab, and a few living men whom we hesitate to name, answering all the requirements of the case.

The art or science, or whatever it may be called, of horticulture is now so vast, and has so many intricate ramifications, that nobody would probably venture to doubt its claims to be considered a branch of knowledge of the highest importance, and worthy of a special study. That such comparatively few prizes as do occur in its high walk should be given to men in an essentially different, though an allied, branch of human knowledge, is not fair to horticulturists. That such things should occur is no doubt partly owing to the fact that horticulturists as yet have no purely horticultural, no thoroughly good preparation for training their own young men in a fitting way. There is no such thing as a properly organised school of horticulture in any country, certainly nothing like it in England. Only a one-sided miserable knowledge of horticulture can be gathered by young men in any one place having pretension to teach the art. If a nurseryman or any other person have a son whom he desires to give full acquaintance with horticulture, there is no place where he could now put him with any certainty of his getting a good all-round knowledge. If there were such a place, and as much trouble was taken in selecting a number of young men as is taken in other professions of no greater importance, there would probably not afterwards be any difficulty in selecting men in all ways fitted for the good management of a national or botanic garden, and with the other acquirements essential for the position. In the meantime we can only hope that little harm will come from the present inaction; and that horticulturists will one day see clearly the urgent need of an organisation for the efficient teaching of an art which is so important in all ways to the true wealth and beauty of every country. A very great deal might be written, showing the injury to the art of horticulture by allowing men to direct important gardens who have no real love for the art and real knowledge of it.

Glasnevin.—In a letter received yesterday from Mr. Norman M'Leod, Mr. Fred W. Moore received official notification of his appointment to the curatorship of the Glasnevin Botanic Gardens. The letter contains a compliment to the late Dr. Moore, which will be read with much pleasure in this city, notwithstanding the peculiarity of its grammar. It says: "Though young for so responsible a post, my lords, remembering how much the Gardens owed to the great ability, untiring energy, and long services of your father, were glad to find by the excellent testimonials you forwarded, and especially by those showing the manner in which you have filled a similar post in the Botanical Gardens of Trinity College, that they would be quite justified in appointing you to it." We understand that the salary of the late curator began at £300 and advanced to £400. From each of these sums £100 has been subtracted in the case of the new appointment. This is rather an overstrained economy, unless the intention of it be to confer the £100 a year as a pension

on Dr. Moore's widow, an application of the money which would give universal satisfaction. There is, indeed, a rumour, but we can hardly credit it, that the intention is to job the £100 a year by creating a perfectly useless office, that of a "Scientific Director," for the benefit of a gentleman, with the nature of whose claims on the Committee of Council we are entirely unacquainted. The Gardens are now a branch of the "National Institution of Science and Art," and this institution has already in the person of Dr. Steel a director who, we presume, possesses all the science that is requisite for the superintendence of the Garden and its curator. There is an adage about too many cooks, which we would commend to the attention of his Grace the Duke of Richmond, President of the Council.—*Irish Daily News.*

THE KITCHEN GARDEN.

AN ERROR AS TO ASPARAGUS.

I COULD not expect "S. D." to be well content under my correction of his mistake about blanched Asparagus. That mistake he and many others defend, and their having wrong ideas in reference to this subject does not matter much, so long as they confine them to themselves. But when people publish erroneous statements betraying that they know but little about the qualities and the cooking of Asparagus, then it is well, perhaps, that others should correct them. He asks how it comes that "in private gardens where the best of everything is produced there is no demand for white Asparagus," implying that it is to be had if desired in most private gardens. This is, of course, a statement more amusing than true. I never saw a good sample of well-grown blanched Asparagus in a private garden in this country; and good green Asparagus is not much more frequent. I was talking to Mr. Gilbert, of Burghey, the other day, who is well known to many of your readers as being one of the best gardeners in England, and he remarked that "when we want large and fine Asparagus we must send to Covent Garden for it." In country gardens people frequently eat the best they can get, and very poor it often is. The London market has lately been full of green Asparagus from France, which is not worth 1d. a bundle to anybody who knows what Asparagus should be. "S. D." contends that "the more there is of the green the better it is." This is quite against the practice of the best English and French market gardeners—those who supply our tables in both countries with the choicest and best Asparagus. "S. D." asked "what can there be in it but crude unconverted sap?" I cannot exactly tell him how many thousand pounds there are in it; but a good many there must be. If he asks any of the best judges in Covent Garden to supply a table in spring, they will give him the best blanched if he can afford to pay for it. By all means let those who like green Asparagus eat it—it is often very delicate and good—but we cannot allow them to prevent all fair consideration of the subject without a protest.

Our markets are full of Asparagus in spring grown in other countries, sometimes as far as a thousand miles from London. It is a vegetable which perhaps more than any other loses quality every day after it is cut. This is one reason why it should be grown in our own country. The soil and the climate of England, in almost every county, are admirably suited for the production of Asparagus. Nevertheless not only do we not supply our own markets, but many possessing large estates cannot get a really good dish to give to their friends, but have to send to Covent Garden for it. All this is wholly unnecessary, for every farmer's garden and every cottage garden might grow it well. In large places, where a few beds formed on a costly and wrong principle now furnish a very limited supply of very poor Asparagus, there ought to be an abundance for everybody. Our markets ought to be supplied by our own people, the early supplies

coming from the south and the late ones from our northern counties.

Speaking generally, Asparagus now is a luxury for the rich only. It is confessed by those who eat it most that it is the most wholesome and the most delicious of green vegetables. It must then be a benefit to make its good and simple culture known throughout the land. The question of blanching is happily somewhat apart from the question of cultivation, and people may adopt the only true and simple system without blanching if such be their taste. But a closer acquaintance with the subject will probably teach many that there is something in this despised system of blanching which so many rush into the gardening papers to declare to be an absurd practice.

V.

SEAKALE FROM SEED FOR FORCING.

THERE can be no question, I think, that Seakale grown from portions of the thong-like roots must be stronger and better after a summer's growth than plants raised from seed, for the simple reason that the former are much in advance of the latter at starting, and are in leaf and growing away freely almost before seedlings are up. Seedlings at a year old have only one crown, whereas plants obtained from roots have two or three, and therefore the yield from the same amount of ground may be safely reckoned at two-thirds more in favour of plants from roots. The practice with ourselves is, when trenching up roots for forcing, to break off any parts that are long and straggling and to save all such for sets, which are cut up into lengths at the time and buried in moist sand or coal ashes under cover till March, when they are planted out in rows at 1 ft. apart. If we do not get sufficient of these we make use of the roots of plants that have been forced, giving preference to the large roots instead of the main stem, which we invariably discard. As the roots for the greater part of their length are nearly or quite of the same size, it is necessary when dividing them into lengths to make a distinguishing cut so that at planting the right end may be put in uppermost, for if they have not made a start at the time it is impossible to tell the top from the bottom. Besides manuring the ground heavily before digging, we give it a sprinkling of salt, which not only keeps down weeds but has a stimulating effect on the plants. The salt is applied at any time during May after the first hoeing, and the ground after that gives no further trouble, but remains clean throughout the whole of the summer. Why Seakale runs to seed is because it is not cut in spring, a time when every crown should be taken off just as it starts, for if not done then the flower-heads have to be removed later on after having weakened the plants. By cropping them off early the roots soon form fresh buds, and these get quickly into leaf, and, having a long season before them, are sure to develop fine heads by the autumn. As soon as they break after having the crowns taken off they should be gone over and thinned out to two or three, for if more are left they must of necessity be smaller and crowded through the strength and energies of the plants being diverted into so many channels. It is not too late to see to plantations even now, as letting in light and air will afford the crowns left a better chance to ripen.

S. D.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Planting out Winter Greens.—The backwardness of the season will, unless extra pains be taken, interfere with the planting of our winter crops and so disarrange the system of rotation. Peas and Potatoes that in the ordinary course would have been gathered and cleared away are now scarcely fit to gather. Peas will not fill up their pods without sunshine, and Potatoes are scarcely eatable when taken out of sheer mud. Where the land is not ready but little harm will come to the Broccoli and greens if they can be pricked out 6 in. or so apart and have the soil stirred amongst them sometimes. In such a nursery-bed they may remain a month without taking much harm, and they will be gathering strength. In some gardens where land is scarce and has to be made the most of, some of the Broccoli and greens have to be planted between the rows of early Potatoes, and in this case there need be no delay in planting them out. All kinds of greens that have to stand the winter should be planted in moderately firm ground. Freshly-dug ground, unless it be land that quickly consolidates, is not suitable. I should never think of planting here on freshly-dug ground, or, if I did, I should expect to see every plant cut off in only a moderately severe winter by the frost. But it takes a very severe winter to injure plants if the land is firm when planted. It need not—it

in fact should not—be poor, but land that has been well manured for a previous crop will be in good condition for Broccoli. The crops on poor land will be much benefited by having a dressing of artificial manure heaped round the plants when they are fairly established and are in a position to absorb a concentrated stimulant that soon passes away or at least is not of so lasting a character as farm-yard manure. A mulching of the latter round the plants on poor land will be beneficial by and by when dry weather comes.—E. HOBDAY.

An Asparagus "Belt."—This part of the country (says *The Rural New Yorker*) ought to have been the native home of Asparagus, for, escaped from cultivation, it grows wild in hedge, field, wood, and meadow. Thousands of acres are under Asparagus, and twenty-acre fields are not uncommon. As here cultivated, there is no such thing as the preparation of the ground to endure for years. Sandy soils are preferred. The roots are planted 10 in. apart and the rows 4 ft. apart. Late in autumn or early in spring a furrow is ploughed directly over the plants, and this is filled with farm manure; a furrow between the rows covers this, and the whole is levelled with wood hand-rakes. Thus its cultivation is continued from year to year upon the same field. No doubt even our western readers know of the celebrated Oyster Bay Asparagus, as if that were a distinct variety; we hear little of it now, not because it is less esteemed, but because hundreds of acres are now cultivated in various parts of Long Island, of the best quality, where one acre was cultivated in years past. The Asparagus "belt" may be considered as confined to the south portion of the island; this receives the salt vapours from the sea. Some deem it necessary to sow salt, others do not, and both seem to obtain abundant crops.

Cabbage Sprouts.—There is one great inducement to cut the first crop of Cabbages early, viz., that what one loses in size by cutting before they are fully grown is counterbalanced by the rapidity with which the stalks produce a second crop of sprouts. During the late spring, green vegetables being scarce and our spring Cabbages tolerably forward, we cut the majority of them very early, and being planted in rich ground in a well-sheltered garden they again quickly started into growth, and now we have a fine second crop consisting of five or six useful-sized Cabbages on a stalk. I often wonder that this system is not more generally followed by cottagers than it is, as it is no exaggeration to say that for half the year they experience a scarcity of good green vegetables. For Cabbages the soil can scarcely be too rich. I generally plant our main crop after the Onions are cleared off, digging the ground deeply and working into it the heaviest rotten manure which we can get and plenty of it. It is now time to prepare for the principal sowings for autumn planting, the second and third weeks in July suiting most localities. Choose an open, well-cultivated piece of ground for the seed-bed, and sow thinly, covering with nets to keep off birds, and dusting with soot and wood ashes to keep off fly. Wheeler's Imperial, Early Battersea, and Enfield Market are good sorts, and some of the small, close-hearted kinds of the Early York type are extremely useful for the earliest crop of both Cabbages and Sprouts.—J. GROOM.

Cutting Asparagus.—A Wisconsin correspondent of the *Germantown Telegraph* writes: "I cut from 5 in. to 6 in. below the surface as soon as I see a spire peeping above it. In making a bed I place the crowns of the plants about 7 in. below the natural level of the ground, covering at first with only 2 in. or 3 in. of soil. I then add loose, friable soil (like sandy wood earth) until the trench is filled. The spires, passing through the friable soil with ease, grow rapidly, and when cut below the surface (as stated) are tender, crisp, and blanched like Celery. When boiled they resemble Marrow in consistency; especially so when cut just after a warm rain. I have cut spires 3½ in. in circumference, but, like all other large vegetables, the extra size did not add to the quality, but rather detracted from it. I could send you a bunch of Asparagus where every spire (5 in. in length) will snap in twain at the butt like a crisp Radish—the entire length being cut below the surface of the ground."

Peas.—I gathered my first Peas, William the First, on June 19, also Kentish Invicta a week later; both sorts were sown in turves in cold frames about the middle of March and planted out in the middle of April. They are ten days earlier than Emerald Gem, sown in the open ground in the same situation on January 6. William the First is better in every respect than Invicta. I have two rows of the first and one of the latter 75 ft. long, raised in three single light frames 6 ft. by 4 ft., each row very fine, while of those sown out-of-doors the first is thin and poor.—J. GARLAND, Killerton, Exeter.

Cutting Cauliflowers.—The following is an economical plan of cutting Cauliflowers, which Mrs. Stephens sends us from *Huish's Alphabetical Receipt Book*, and which she recommends where there is a large family, as she has for years proved its usefulness:—"The most economical plan of cutting Cauliflowers is, instead of cutting off the whole head of a Cauliflower, to leave a part on, and all the leaves,

folding them over. By this method second and third heads will be formed, and thus they may be eaten for two or three months; whereas at present, by cutting the head completely off, the bed of Cauliflower is exhausted in two or three weeks." She leaves a little branch on two sides, as large as a small egg, and thus has many times had two and even three cuttings from one plant.—*Florist*.

THE PLOUGH IN THE GARDEN.

It may interest "C." (p. 5) to know that the plough is already largely used in this locality where the spade was but a few years ago employed, viz., in Hop plantations and market gardens, and doubtless on a large scale the plough may be introduced in such a way as to materially lighten manual labour. Kitchen gardens are not so well kept as formerly, owing to the fashionable style of bedding-out absorbing so much attention. Table and indoor decoration, too, have grown to such an extent that the kitchen garden is deprived of its fair share of labour, and whether we adopt the plough with an extended area, or higher cultivation, in order to get a maximum of produce from the smallest surface, will not materially affect the cost of keeping up gardens where three-fourths of the labour are expended on purely ornamental non-producing work. Except in very large kitchen gardens even one horse could not be kept profitably employed, and yet the cost of keeping a horse is no light matter; besides, a man's time is spent in connection with the horse, and in gardens a driver must also be employed, and boys are not available for employment now until they get old enough to require comparatively high wages. In the adhesive land in this district, one horse might just loosen the surface, but it would take three to go deep enough for good vegetable culture. In the neighbourhood of London, in the Thames valley between Fulham and Richmond, where rent, labour, and every item of culture is far higher than in any other part of the kingdom, and where growers do not study appearances, but are guided entirely by the quality and returns of their crops, produced on the cheapest principle, with no edgings or foot-paths, or fruit trees to fetter their movements, I know that the plough is used as well as all other labour-saving appliances; but there are such multifarious operations connected with private gardens that can only be done by manual labour, that the work of cultivating the soil ready for the crop becomes a minor affair. Your correspondent finds fault with the designs of kitchen gardens recently published as following too closely the old beaten track; but who would have sent in a sketch of an open field, such as may frequently be seen in large establishments where the Potatoes, Turnips, and Broccoli are grown by the acre, and which, properly speaking, could not be called a garden at all? Kent, with its wealth of orchards and Hop gardens, has been justly called the garden of England, where plenty of labour has been employed to keep even the hedgerows as clean as gardens are in most counties; but a succession of bad harvests, and the slovenly manner of working the soil with the plough on the plea of economy, will soon destroy any claim to superiority of cultivation which it once enjoyed. Kitchen gardens are already in most cases large enough to supply all the wants of the household, and all they want is not to be unduly overshadowed by the ornamental departments. J. GROOM.

Linton, Maidstone.

—The utility of the plough in the garden instead of the spade is, I fancy, more theoretical than practical. "C." may have some particular garden in his mind's eye, but I imagine that as a rule gardens under spade cultivation are better kept, better cultivated, and produce heavier and better crops, acre for acre, than the best model farm in the country. To prove that spade cultivation is superior to that of the plough, one has only to look into an allotment field where spade cultivation is practised, and in some cases enforced; there will be found crops greatly superior to any on the adjoining farm.—J. M.

Painting Flowers upon Mirrors.—An art lately revived in Rome is the old Venetian art of painting upon mirrors. Birds and butterflies are also often added, and the effect of the glass underneath, especially when this is thick and bevelled, is to make them appear as if suspended in the air. Tourists remember seeing them in Venetian palaces, but faded and flecked with time, and often also coarse and heavy in design. Now the execution is much finer, and besides our flowers are enriched in quality and variety. Fornari is the best artist for this work in Rome. His flowers are poised and painted with a grace and delicacy that nature, so reluctant to give up her subtle secrets, has herself granted him. The design must be traced from natural flowers with a lithographic pencil, and painted in oils with peculiar care, for nothing can be more unlovely when badly done with muddy, ill-assorted colours. These mirrors are usually framed in carved ebony or ebonized frames in the cinquecento style, another fashion recently revived.—*Syracuse Journal*.

CULTURAL USES OF LIME SUMMARISED.

THE advantages of the use of lime are so many and so great that it is almost impossible to enumerate the whole of them. Their effects may be described as being both chemical and mechanical, and as being exercised both upon the organic and the inorganic constituents of the soil. The following may be taken as a summary of some of the principal benefits to be derived from it:—

1. Upon deep alluvial and clay soil it increases the crop of potatoes, and renders them less waxy. Sprinkled over potatoes in the store-heap it preserves them, and when riddled over the cut sets, it wonderfully increases their fertility.

2. Lime eradicates the finger-and-toe disease in turnips, and gives greater soundness and more nutritive qualities to the bulbs.

3. It gives, when applied to meadow land, a larger produce of more nutritious grasses. It also exterminates bent as well as coarse and sour grasses, destroys couch-grass, and acts powerfully upon the rye-grasses.

4. Upon arable land it destroys the corn-marigold, and weeds of various kinds.

5. It rapidly decomposes vegetable matter, producing a large amount of food for plants in the form of carbonic acid gas.

6. It destroys or neutralises the acids in the soils; hence its adaptability to sour soils.

7. It acts powerfully upon some of the inorganic parts of soils, especially on the sulphate of iron found in peaty soils, and the sulphates of magnesia and alumina.

8. It proves fatal to worms and slugs, and the larvæ of injurious insects, though favourable to the growth of shell-bearers.

9. Slaked lime added to vegetable matter causes it to give off its nitrogen in the form of ammonia. Upon soils in which the ammonia is combined with acids it sets free the ammonia, which is directly seized upon by the plants.

10. Its solubility in water causes it to sink into and ameliorate the subsoil. When the soil contains fragments of granite or trap rocks, lime hastens their decomposition and liberates the silicates.

11. Its combination with the acids in the soil produces saline compounds, such as potash, soda, &c.

12. Strewed over young plants, it destroys or drives away the turnip fly.

13. Worked in with grass seeds, the beneficial effects of lime, chalk, marl, and shell sand have been visible for a period of 30 years.

14. Applied to the rot heap, lime effectually destroys the seeds of weeds.

To sum up its advantages—When properly applied to the soil it purifies and stimulates its action, thereby promoting the growth of healthy vegetation of all kinds.—*Journal of Forestry.*

WOODLAND LAKES.

THE treatment of ornamental water in pleasure grounds is a subject that has been frequently discussed, but I do not recollect anything having been said concerning woodland lakes; yet the "Lake of the Woods" is a feature of at least a few noblemen's demesnes with which I am acquainted, and few spots are more attractive to lovers of Nature in its quieter and more solitary aspects. In ornamental pleasure grounds generally there is usually a certain amount of bustle, or at least the signs of it, present, which to some extent detracts from their enjoyment, and one longs to escape at times from the artificial dressiness and "keep" of the garden to some spot where the hand of man is less apparent, and Nature wears a simpler and more primeval aspect. Such a retreat as this the woodland lake ought to be—a deep, still, and extensive sheet of water in the solitudes of the forest, and surrounded by dense native vegetation chiefly, for in such a spot gay exotics would be an incongruity and inadmissible, though they might be associated with the wild garden, perhaps, but not too closely. A lake of this description which I have seen and remember well, may be worth describing here. It was situated about half a mile or more from the mansion, but had no connection with the flower garden or ornamental grounds, from which, however, it was reached by a half-concealed Grass path that led the visitor to a secluded ravine in the wood, where a sudden turn brought him in full view of one of the sweeps of the lake, reposing in the dense shade of the tall Pine trees with which it was surrounded, and whose deep shadows on a calm summer's day were mirrored on its bosom. The margin of the lake was thickly fringed with drooping Willows and Birches, &c., that dipped their lower branches in the water, and the background on every side was a forest of Pines, except where here and there a jutting knoll was covered by Bilberry bushes and Ferns. A narrow, half-concealed path wound round the edge of the lake, and here and there, at the most attractive spots and vantage grounds, a rustic seat was placed for the convenience of visitors, and a skiff was also provided for those who wished to enjoy

a sail, or to fish for the trout which abounded in the lake. Everything about the lake wore a perfectly natural aspect, which was enhanced by the dense masses of Bulrushes and Reeds which fringed its margins in some parts, on which coots, water hens, and wild ducks found a safe retreat. It was a warm, bright, sunny day at the time of my visit, and a more delightful retreat of the kind I thought I had never seen. Far removed from noise and tumult, everything was so still and quiet that the spectator might have fancied himself in the midst of some virgin forest. I have often thought since that in such a spot telling effects might be produced by the judicious use of fine-foliaged sub-tropical plants. The shelter from wind was perfect. Shut out on all sides, a gale hardly ruffled the surface of the lake, while on summer days the sun shone down upon the water with a fierceness that was almost unbearable, and all that was needed to give the scene a half-tropical aspect was a few well-placed groups of Palms, Bananas, Dracænas, Cannas, and such like. As it was the lake was a favourite resort for the proprietor and his guests, who frequented it perhaps oftener than any other portion of the extensive grounds, which is saying a good deal for the attractiveness of such retreats. Speaking of sub-tropical gardening in connection with this subject, it has always struck me that attempts in that direction are very often marred by the absence of water. Luxuriant foliage and half-aquatic subjects placed on dry knolls, or on trim plots on Grass lawns, are rather incongruous objects, but growing near the margin of water, and in a half-natural situation, they seem at home and are effective. In the otherwise wonderfully well-arranged grounds in front of the Trocadéro, at the Paris Exhibition, a singularly artificial effect was produced by the introduction of plants of the Egyptian Papyrus upon rising ground, considerably above the eye of the spectator—the last place in which one would have looked for such a subject.—*Field.*

The Cold Season.—According to *Nature* there have been, during the last 115 years, four other periods of protracted cold similar to that which we have lately experienced—that is to say, periods when the mean temperature of each month was below the average of that month for many months in succession without intermission. These periods were as follows:—1. A period of nineteen successive months extending from September, 1798, to March, 1800. The mean temperature during this period was 2·8 deg. below the average. 2. A period of seventeen successive months, extending from September, 1859, to January, 1861; mean temperature 2·2 deg. below the average. 3. A period of fifteen successive months, from October, 1815, to December, 1816; mean temperature 3 deg. below the average. 4. A period of fourteen successive months, from February, 1782, to March, 1783; mean temperature 4·4 deg. below the average. The more ample meteorological data now obtainable allow the distribution of heat or cold to be more accurately defined than formerly. During the past cold weather the cold in the British Isles was, it appears, most severely felt in the central part of England, within an area bounded by Stonyhurst, Shrewsbury, Cirencester, Oxford, Audley End, Yarmouth (Norfolk), Kelstern (Lincolnshire), and Durham. Within this area the mean temperature from December, 1878, to May, 1879, was 6 deg. below the average, and in some places more; at Cirencester it was 6·7 deg., and at Shrewsbury 7·4 below the average. In the central parts of Scotland and Ireland the mean temperature of the same period was about 5 deg. below the average. Everywhere the cold was less felt on the sea coast than inland.

Hiding a Light Under a Bushel.—The garden of St. Paul's Cathedral is like a light under a bushel, for it is enclosed with a heavy palisade that effectually screens it from view, and suggests that the ironwork is the proper adornment, and the garden a mere accident or makeweight. This is a common error in municipal gardening; at all events in London. Usually, however, we have a heavy and consequently opaque palisade, and within that a grimy Privet fence, and thus the passer-by sees nothing but the brown boundary and a few tree tops that show themselves above it. I shall once more refer to Queen Square, Bath, as a model in respect of such matters. There the passer-by can see the green sward and the elegant trees, and may even be deluded into the belief that he is walking through a garden.—*Gardener's Magazine.*

The Middle Temple.—Great improvements have been recently effected in the small but compact gardens belonging to the Middle Temple, more especially in that part which leads from the Thames Embankment up by the side of Garden Court, which now presents a remarkably pretty appearance, having been converted by Mr. Snelling, the head gardener, into a series of what are called "carpet" beds. The Temple fountain, rendered famous by Dickens in "Martin Chuzzlewit" as the meeting place of Tom Pinch and his sister Ruth, has also been renovated, and the basin will be planted with Water Lilies, while the beds surrounding it are already filled with fine-foliaged plants.

GILBERT WHITE'S GARDEN.

Romantic spot! from whence in prospect lies
 Whate'er of landscape charms our feasting eyes—
 The pointed spire, the hall, the pasture plain,
 The russet fallow, or the golden grain,
 The breezy lake that sheds a gleaming light,
 Till all the fading picture fail the sight.

Gilbert White.

THERE must be few readers of the "Natural History of Selborne" who have not at one time or another experienced a curiosity to visit the dwelling-place of its accomplished author. Many doubtless have long since satisfied such curiosity, but there must be others to whom the neighbourhood of Selborne is still a *terra incognita*, and to whom, therefore, the following remarks may be acceptable.

A glance at the map of Hampshire will show that the village lies in the eastern corner of that county, bordering on

Walking leisurely along we here and there get a glimpse through some opening of a beauteous woodland scene or field covered by Hop-vines. Amid such rural scenes—amid so much that is pleasing and lovely, we are reminded of the lines of Clare:—

"Upon a molehill oft he dropt him down,
 To take a prospect of the circling scene,
 Marking how much the cottage roofs thatch brown
 Did add its beauty to the budding green
 Of sheltering trees it humbly peeped between.
 The stone-rocked waggon with its rumbling sound,
 The windmill's sweeping sails at distance seen,
 And every form that crowds the circling round,
 Where the sky stooping seems to kiss the meeting ground.

Crossing a bridge over the well-head we ascend a short rise and at once come upon the Plestor. In the centre of it, and surrounded by a wooden seat, stands a fine Sycamore;

Gilbert White's Garden, (April, 1879).

the county of Sussex, and is easily accessible from Liss station on the direct Portsmouth railway, a pleasant walk of 5 miles. On reaching the village of Liss, which lies at a short distance from the station, we pass the "Blue Bell" inn on the left, and further on the "Spread Eagle," leaving which, also on the left, we come in view of the church. Like many of its class, this has been much added to in different styles and at different times, the modern brick porch ill according with the Norman stone windows. Quitting the church, and following the road to a toll-bar and cross roads, we take the road to the left, and soon approach another cross road, where a finger-post points "to Hawley and Emshot." Choosing the Emshot road to the right, we follow a pretty lane to an old picturesque cottage standing almost in the corner of three cross roads; continuing past this cottage, a winding road brings us to the village of Selborne, lying in a valley, and surrounded by woody hills.

while to the left, and close by the churchyard wall, is a large Horse Chestnut, the adjacent cottages being covered with Roses and Honeysuckles. Proceeding a few yards further the vicar's house appears, and beyond the churchyard gate. Entering this, the old Yew tree, which White so particularly notices, at once attracts attention. He gives its greatest measurement as 23 ft. in his day, but it must be now nearly 24 ft. The church is a primitive-looking building, with a heavy-tiled roof; at the west end a square embattled tower 45 ft. high somewhat relieves its low equal appearance, but everything in and around is wonderfully clean and neat, and there is an air of sanctity about the place which checks the too exuberant spirits of the curiosity-seeking tourist.

Now, as in White's time, the south side of the churchyard seems to be the favourite resting place, but passing over many gravesround by the chancel, we come on the south side to the last home of Gilbert White. All that tells the story is a simp'e

stone about 18 in. high and 15 in. broad, rounded at the top, with the inscription "G. W., 26 June, 1793." Retracing our steps back through the Plestor immediately to the right, we come to the residence of White. The house remains very much in the state in which White left it, excepting that a wing has been added at the west end by the present owner and occupier Mr. Bell. The grounds are probably in better order than when White owned them, although nothing characteristic of the former occupant has been destroyed. The brick-laid walk, the old sundial, the large Oak and the Cedar are still there, and we have only to imagine that the former venerable owner is, for the time, absent from home.

Again passing along the village, still much as it was in 1780, "a long straggling street," some houses thatched, others like the church with square tiles, we come to a path leading up to "the Zig-zag," and as we ascend a magnificent view of the surrounding country is obtained. This hill rises above the village about 300 ft., and is divided into a sheep-down, a high wood, and a low wood called "The Hanger." This wood consists entirely of Beech, and growing as it here does on chalk, attains a beauty rarely acquired elsewhere. "In a district so diversified with such a variety of hill and dale, aspects, and soils," wrote Gilbert White in his forty-first letter to Daines Barrington, "it is no wonder that great choice of plants should be found. Chalks, clays, sands, sheepwalks and downs, bogs, heaths, woodlands, and champaign fields, cannot but furnish an ample flora. The deep rocky lawes abound with Filices, and the pastures and moist woods with Fungi. If in any branch of botany we may seem to be wanting it must be in the large aquatic plants, which are not to be expected on a spot far removed from rivers and lying up amidst the hill country at the spring heads."

To enumerate all the plants that have been discovered in the parish would be beside our present purpose. The reader may be reminded that White himself, in the letter just quoted, has given a short list of some of the rarer plants of Selborne and the spots where they are to be found, and this account has been supplemented by the late Dr. Bell Salter, who published in the "Phytologist" (Vol. I. p. 1132) a list of the flowering plants observed by him at Selborne during three days botanising in the month of September.

Sitting on the sheep-down we look around and over those scenes so faithfully described by White. In the distance is Woolmer Forest and Pond; close by to the right is Nore Hill, beautifully wooded; below nestles the quiet village; and far away stretches the lovely scene, till the view is closed by the horizon on the far-famed downs of Sussex. Nothing disturbs the solitude but the halting tinkle of the sheep-bells as the sheep move over the short turf. Looking down from this eminence the swift and swallow are seen sporting below as in the days of White; while from the woods the mellow notes of the blackbird and thrush ring out as they did eighty odd years ago.

How is it that with these simple materials Gilbert White has produced a book which is prized so much by young and old, by scientific and non-scientific readers? Doubtless because he described everything simply and truthfully; recorded only as facts such as could be proved to be such; and never forgot that one Hand only fashioned all the objects which it gave him pleasure and interest to observe, and that the same Power regulates their continuance or change. In his forty-ninth letter to Daines Barrington, he says: "It is now more than forty years that I have paid some attention to the ornithology of this district without being able to exhaust the subject; new occurrences still arise as long as any enquiries are kept alive." And this was written of a single parish! It shows very strikingly that natural history, when studied in

the way in which Gilbert White studied it, is no mere waste of time as too many suppose. H.

P.S.—Mr. Binney has now been Mr. Bell's gardener here for about thirty-five years. The garden was in a most charming condition at the time when we visited it at the end of April of the present year. It contained immense tufts of old double white Primroses smothered with flowers, and many double Rockets. As will be seen from the sketch, the lawn has been kept intact and has not been disfigured by formal flower-beds, and therefore forms a pretty foreground to the fine old house. When Mr. Bell acquired the property the garden was in a ruinous condition—in fact, quite a wilderness. With the exception of the Yew tree, and the Elm that stands at the north-west of the house, all the trees within the fence were planted by Mr. Bell. *Pinus Pallasiana* and *P. nigricans* were from small seedlings about 4 in. high; they have now attained about 30 ft. *Picea cephalonica*, planted at about 2 ft. high, is now rather taller than the former. *Abies Douglasi* is considerably upwards of 70 ft. *Sequoia*, Cedar of Lebanon, and several other species have made equally remarkable progress. *Populus alba* exceeds 100 ft., and every year throws out suckers to fill that distance. The Maples far exceed, in point of height and size, any in the neighbourhood. One of the most remarkable trees is the *Ulmus montana*, which grows about 50 yards from the house, a somewhat particular account of which is given in a note at page 5 of the first volume of Mr. Bell's edition of "White's Selborne." V.

PROPAGATING.

Propagating Primulas from Root Cuttings.—At a meeting of the Scientific Committee of the Royal Horticultural Society at South Kensington, a letter from Mr. I. Anderson-Henry was read on this subject. "I have observed means by which Primulas may be propagated to any extent, and it strikes me that if it is unknown it might be worth communicating. I had raised from seeds sent me from Ladak and Kashmir a great many of the tribe, and as I could not accommodate them under glass, I caused them to be planted out in beds. They were of the *P. denticulata* type, and principally, I believe, the true *P. purpurea*. After having stood the winter, and having occasion for the beds last spring, I had them dug up and removed. I filled up their space with other plants more prized, and amongst these I now find the Primulas coming up like weeds. I find in digging them up that fibrous roots had been cut off, and from these have sprung the numerous progeny I now have to remove as weeds."

Propagating Verbenas.—When plenty of free healthy cuttings can be secured the propagation of Verbenas is an easy and satisfactory matter. Strong succulent shoots will under favourable circumstances emit roots in a short space of time, whereas if the wood is at all stunted or diseased the best of care will not ensure success. Cuttings made from unhealthy wood, even if they root fairly well, can never make robust plants. Many disappointments in the culture of this useful bedding plant might be traced back to a lack of vigour in the cutting. It is a great mistake to rely entirely upon the bedded-out plants for a supply of cuttings. The plants are just at their best when propagation should be begun, and the chances are that very few suitable shoots can be found. I have often experienced a deficiency in this way, more especially in dry seasons, and with such varieties as Purple King, which, like all other close-growing floriferous kinds, is apt to completely exhaust itself in flowering. A few plants of each variety planted by themselves in a rich piece of ground and kept well supplied with water, picking off the blooms as often as they appear, will as a rule furnish more and better cuttings than a whole garden full which have flowered in the usual way.—J. C. B.

Propagating Grape Vines.—I have raised thousands of Grape Vines in the following manner: Take a last year's shoot near the ground, dig a narrow trench 2 in. or 3 in. deep, bend down the shoot, fasten it with hooks on the bottom of the trench, and leave it until the sprouts from the buds are 3 in. long; then bury it and it will root at or near every bud. In autumn take it up and cut it into pieces, leaving roots attached to every piece.—Country Gentleman.

THE FLOWER GARDEN.

LANTANAS AND THEIR CULTURE.

LANTANAS are plants that bear trusses of flowers not unlike those of the cultivated varieties of *Verbena*. Their prevailing colours are pink, yellow, orange, and different shades of red; their blossoms emit a peculiar aromatic perfume agreeable to some, but disagreeable to others. Many treat *Lantanas* as stove plants, but that is unnecessary, as they succeed better in a greenhouse, and they are as easily cultivated as a *Pelargonium*. They may be readily increased by means of cuttings made of the half-ripened wood, which roots freely in a hotbed; they may also be raised from seeds which ripen on the plants when they are grown in a greenhouse rather freely exposed to the light, or if they are planted on a warm border out-of-doors the seeds may be sown as soon as they are ripe or in the spring. Sow in a hotbed or in a propagating house, using fine soil; the treatment of the young plants whether raised from seeds or cuttings is the same. Pot them off singly in small pots, and when they are 3 in. high pinch out the centre; this will cause a number of growths to start, when they may be repotted into 3-in. or 4-in. pots. The most suitable compost for them is turfy loam and turfy fibrous peat

Hybrid Lantana.

in about equal proportions, with the addition of a little leaf-mould and sand; they would not object to manure, but that induces an over-luxuriant growth. The pots in which they are grown should be well drained, and when they have become filled with roots abundant supplies of water must be given. If the cuttings be put in early, good-sized flowering plants can be obtained the same season, but the largest and best flowering plants are old ones cut down in the winter and started into growth early in the year. Good-sized specimens may be flowered in 8-in. and 9-in. pots. Those who can grow *Fuchsias* and *Pelargoniums* well would be equally successful with *Lantanas*. They also make a good border or bedding plant, producing flowers in abundance during the autumn months. In Mr. Fraser's nursery at Lea Bridge, *Lantanas* have been planted out close to a low wall belonging to one of the greenhouses, and there they annually make a very good display planted in the ordinary soil of the garden; they also succeed in ordinary loam cut from any pasture land if peat cannot be obtained for them. The effect of peat is to infuse into the foliage a dark, healthy green colour when grown in pots. The following are amongst the best varieties that have yet been raised, viz., *Adolphe Hoass*, *alba lutea grandiflora*, *Corbeille d'Or*, *Don Calmet*, *Souvenir de Pékin*, and *Vulcan*.

JAS. DOUGLAS.

NEW FUCHSIAS.

It has been observed that the *Fuchsia* has made little or no advance during the last few years, but that is a mistake. For instance, *Bland's New Striped* is in every way a first-class *Fuchsia*, and quite equal—in shape, colour, growth, &c.—to Mr. Banks's best; indeed, it very much resembles the well-known *Enoch Arden*, from which it must have been a seedling. The striped kinds have hitherto shown the markings in their corollas very faintly, but this presents a very bold, distinct, and regular stripe, and when seen in its best state it is the admiration of all beholders.

Jeanne d'Arc, by reason of the perfection of its unequalled flowers, leaves all those varieties with a white corolla far behind; its pearly-white is most lovely. In fact, it is in all respects a most charming *Fuchsia*, its corolla being very large and spreading.

Kingsburyana has something of the same character, but has a double corolla, which is very large and spreading. In this flower part of the corolla is attached to the calyx-tube; and in some flowers these parts are connected for quite half the length of the underside of the reflexed sepals. It is a strong grower and very showy.

White Giant is another somewhat similar to the preceding, with very large double flowers. This and *Miss Lucy Finnis* show a decided advance on all others in the class of varieties with white corollas, and they are now grown for market in great quantities, both in Europe and America.

Mr. Lye has added several very strong-growing sorts carrying very large racemes of bloom. Thus *Blushing Bride* is particularly striking, and may probably some day form a good-sized tree in some sheltered situations. It has a white tube and sepals, with scarlet corolla, and is in all respects a very good flower.

Lord Beaconsfield is a very strong-growing novelty bred from *F. fulgens*, and producing large bunches of flowers almost continually throughout the year, so that for cut flowers it is especially valuable; and although its colour is not very striking, it makes a capital outdoor kind.

Aurora superba is another very desirable kind, somewhat resembling the preceding, but with far more attractive flowers, which present a decided yellow shade not previously seen in the *Fuchsia*.

Ethel is one of the varieties with a pure white tube and sepals, the tube being most unusually long, often 3 in. or 4 in. in length, with well-reflexed sepals, and a bright lake-coloured corolla, which peculiarity, together with its long tube, gives it such a remarkably distinct appearance that few forget it who have once seen it.—H. CANNELL, in *Florist*.

A CHESHIRE LILY BED.

I HAVE lately been anxiously looking for something about Lilies from Mr. Wilson, whose notes published from time to time in the *GARDEN* have been my best guides in my attempts to grow these fine flowers. I ask you to allow me to state my brief experience, not so much for the guidance of other beginners, as in the hopes of eliciting some remarks from experienced growers which may be of general interest. My garden is cold and wet, the natural soil being stiff red clay; but I have done much to it in the way of drainage and artificial soil. I have made Lily beds under a wall facing south-east, on a raised terrace, moderately shaded and sheltered. The clay has been dug out to a depth of 4 ft., and the beds perfectly drained; my best bed, of which I now write, has been composed almost entirely of peat soil, of average quality. The surface was planted, according to advice, with suitable evergreen shrubs, such as *Andromedas*, *Ericas*, &c. About these I may remark that *Erica mediterranea* looks very gay in spring, and *Menziesia polifolia* is now flowering well; though the white varieties of both of these are comparatively tender, and suffered last winter. I find the best Heath for appearance in winter, adapting itself as it does to any soil, to be *Erica vagans*. But the most satisfactory of shrubs in this peat border of mine is *Penettya speciosa*: its gay pink shoots and glossy green leaves passed through last winter entirely uninjured, whilst *Laurustinus* and *Berberis Darwini* were killed to the ground in every part of my garden. It is now in full flower, and will soon be ornamented with berries; it grows fast, and may easily be trained in any direction by pegging round, rooting quickly at the layers.

But to return to Lilies: most of those in this bed were planted in autumn, 1877, or from pots in spring, 1878, and I only mentioned those of which I planted several bulbs. The species that seems inclined to monopolise the bed is *pardalinum*; bulbs which last year made a single stem with two or three flowers have this year increased to five or six stalks, with from five to fifteen buds on each. My

chief difficulty with this Lily is to save it from being broken by our violent westerly gales, which find their way everywhere. It is already 7 ft. high, and the stalks are very soft and fragile. If I tie them tightly to a stake the whorls of leaves carry up the tying material until it bends and breaks the stalk. If I allow the flowering head much play, the wind breaks it off. I find the best plan is to put bands of raffia round the stalk, allowing them to rest loosely on the leaves, and to tie them loosely round an iron stake. The band is then carried upwards with the growth of the plant, and slides up the stalk. L. Humboldti seems to require more time to establish itself; all the buds of it live, but most of them make shoots about 9 in. high, which then go blind; about one in four have, in this their second year, made a stem not much thicker than the stalk of a clay tobacco-pipe, bearing five or six buds. They will probably do well, with patience. I am less successful with L. canadense; several bulbs which flowered last year have entirely disappeared; my stock is reduced to two or three marked "californicum" (which I am told is a synonym of canadense), bearing either a single bud or none. I planted monadelphum (Szovitzianum) rather largely; many of them are now in flower; they look vigorous, but few have more than one flower. I may remark that hitherto those in the peat flourish better than others planted in good loam; but the case may be different next year. I feel doubtful whether I shall succeed well with Liliun auratum; many bulbs flowered well last year, but look weaker this year, though none have died. They are just beginning to show their buds, and may improve in appearance before they complete their growth. L. superbum comes up capriciously. It was the latest to appear above ground. It shows some strong heads, though many bulbs planted have not come up at all. It must be very late this year in flowering.

Besides those mentioned, I have planted some other Lilies, but not in sufficient number to pass judgment upon them yet. I may remark, however, that I have failed to make any varieties of L. elegans grow, either in peat or loam. Perhaps this soil and climate are too cold for it. In this same bed with the Lilies, Trillium grandiflorum flowers grandly and increases rapidly. Cypripedium spectabile and C. pubescens have also proved hardy, and do well, but I cannot succeed with C. Calceolus. Gentiana acaulis makes a brilliant spring edging, and all the Dodecatheons feel at home. In conclusion, may I ask if some experienced grower of Lilies will tell me whether I am right in thinking that some Lilies, after transplanting, often remain dormant for a whole season? I was absent from home for two months of last summer, but I thought that I discovered in autumn that bulbs of L. Humboldti and Szovitzianum, planted the previous autumn, had not come up, though they have made healthy growth now. Last autumn, however, I transplanted a large number of L. pyrenaicum, L. tigrinum, and L. candidum, many of which have as yet shown no signs of growth, though the bulbs seem healthy and sound. I have heard that some terrestrial Orchids have this habit.

C. W. Dod.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

A Roseless June.—Amid all the peculiarities of a season that has been unique and unseasonable throughout, the deprivation of Roses in June was one of the most peculiar and the most trying. Of course the term "Roseless" is used in a general and not an absolute sense. There were here and there a Tea, and perhaps in specially favoured localities an isolated Hybrid Perpetual or two; but throughout the great portion of the northern and eastern counties the month was Roseless as far as the Hybrid Perpetuals and summer Roses were concerned. Doubtless a fortnight's forcing weather will do wonders, but we could hardly force Rose-buds into blossom when they are as yet little more than formed. Roses, however, though late look promising. With the exception of a sprinkling of fat grubs and worms in the bud the foliage is clean and healthy, and the hardier varieties show a good head of incipient flowers. The Rose, in fact, seems to enjoy the rains almost better than most plants. While the incessant dampness has kept the foliage clean the shoots show no signs of mildew. The winter, so long and cold, told heavily upon some of the more tender, and these, unfortunately, as a rule, prove also the most rare and beautiful of the Hybrid Perpetuals. The mortality was heavy. Many of the Teas also suffered severely. The Maréchal Niel seems far hardier than most of the other Teas or Noisettes; Lamarque, Celine Forestier, and Devoniensis, for example, are nowhere in hardness beside the Maréchal. We find it the most useful to us as a standard. It never fails to flower well twice—sometimes three times—in the year. By having a few plants under glass, on walls, and as standards in different positions we may generally count on the Maréchal from February to November. It thus becomes invaluable, and the flowers are so different upon the different plants, varying so much in colour, substance, size, and even fragrance, that the Maréchal becomes as good

as half-a-dozen or more varieties. Celine Forestier is another Rose that takes a considerably wide range of form, colour, and size. How lovely it is, for example, delicately tinted or marbled with pink! how beautiful in clusters of buds of different sizes, from three to seven together! and how elegant as shown in single buds just half opened, that most charming of all conditions of Rosehood. But writing of a Roseless June, it is rather out of tune to go off in a rhapsody about the beauty, distinctness, or usefulness of any Rose in particular. There is, however, this excuse in the present case—these two, Safrano and the never-failing, never-killed Gloire de Dijon, are all the Roses that have yet opened freely with us in the open air.—D. T. Fisii.

Cultivation of Linnæa Borealis.—To us this seems a very simple subject, inasmuch as little has to be done beyond planting healthy young plants in a moist sandy border or rock garden, or slightly raised bank. We have always seen the plant thriving freely as a sort of edging to masses of choice dwarf shrubs. Of course we refer to the districts where the air is pure and the soil is fitted for it. The following somewhat elaborate directions are translated in a contemporary: The principal conditions to ensure success are protection from strong winds, shade from the mid-day sun, and a constant and uniform degree of moisture of the soil. The necessary shade is easiest provided by placing the plants on the north side of a building or on the north slope of a hill. Uniform moisture is easily attained by removing 1½ ft. of earth and replacing it with potting mould and Pine leaves or Fir leaves, and the soil immediately around the plants should be covered with Moss. During prolonged droughts the plants should be watered; and to keep them secure against suffering from too much wet from protracted rains the ground should be drained by introducing stout, half-decayed Fir branches near the surface. Branches of Spruce Fir attached to a lattice framework form a good shade, and need renewing only about once in the summer. The best season for transplanting the Linnæa from its native haunts to the garden is the autumn, and it should be carefully lifted with a quantity of earth attached, and thus transferred to its destination. The seed should be sown as soon as ripe, as it quickly loses its vitality, especially if exposed in a dry atmosphere.

Zonal Pelargoniums—The collections of these grown yearly at Chiswick afford admirable opportunities to observe what progress is being made by raisers in regard to the production of improved varieties, both for pot culture under glass and in the open ground. It is thus possible now and then to make selections of kinds that are not yet common or known to growers generally. Amongst deep-coloured varieties stands out prominently Charles IX., a grand rich scarlet-crimson of fine form, and carrying large trusses; this is a good pot kind, and altogether first-rate. Near to this is Titania, one of Dr. Denny's superb kinds, in colour deep rosy crimson, of fine form and exceedingly beautiful; this is an acquisition. Col. Seeley too is a beautiful variety of a brilliant rosy-scarlet, very distinct, free, and of fine quality. Of white kinds, a seedling of Dr. Denny's, not named, is a great improvement on all of that hue; it is very pure, of fine form, large in the pip, producing an abundance of trusses, and making a first-class pot plant; this kind must be looked for by all who grow zonals. In Lady Eva Campbell we get a very pleasing hardy salmon-carmine, allied to fine form and substance, a beautiful chaste flower and a good pot plant. Of pink shades, the richest, and evidently the best, is Mr. Leavers, one of Pearson's seedlings, in colour deep rosy-pink, and marvellously free. This half-dozen would make a valuable addition to any private collection, grown for exhibition or for house decoration.—A. D.

A New Variegated Myosotis (M. dissitiflora) has, says the *Irish Farmer's Gazette*, been raised in the garden of Mr. Percy and Lady Annette la Touche, at Newberry, in Kildare. It has maintained its character for two years, and has been extensively propagated, both by cuttings and division of the roots, so as to have been used largely as an effective indoor decorative plant, and for bedding purposes in the flower garden. The bold and elegant variegation of the leaves, the bright blue, with small yellow eye, of the flowers, the particularly neat and compact habit of the plant, and the facility with which it may be multiplied, combine to render it particularly suitable for bedding purposes. The plant was shown at one of the meetings of the Royal Horticultural Society of Ireland, and had a certificate and the Society's bronze medal awarded to it.

Arenaria balearica.—I hope that Mr. Wood (of Woolville, Kirkstall) will not take it amiss if I point out that he seems not to possess the above plant (*A. balearica*) at all; the description "it has glaucous foliage, and large white flowers possessing great substance," cannot apply to the plant in question. *A. balearica* is one of the most diminutive plants known, about one-fourth of an inch high, of an intense deep green, sprinkled with minute starry flowers; in fact, when seen clinging to the base of a wall, or creeping over a stone, it may be compared to a piece of green plush sprinkled with

silver spangles. I merely write to prevent any other plant doing duty for the plant in question. If Mr. Wood will send me a bit of his plant, I may be able to tell him what it is, and will send him a bit of the true *A. balearica* in return.—THOS. WILLIAMS, *Ormskirk*.

Eulalia japonica zebrina.—Last year I had a very vigorous plant of this *Eulalia* strongly developed with cross bands, or rather chevrons. This year the same plant shows nothing of the sort, but instead of the cross banding, a white stripe shows itself on every leaf. It may be difficult to account for this fickleness, but how does the plant develop itself in other gardens?—H. T. ELLACOMBE.

DOUBLE CLARKIAS.

CLARKIAS deservedly rank amongst the most charming of hardy annuals; they are robust in growth and branching, and they flower profusely for a long period. Curiously enough, whilst many plants

A Double Clarkia.

of this class seem all the worse for the production of double flowers, double Clarkias are an improvement on the single ones. There are three types of Clarkias—first, *Clarkia elegans*, a native of California, which grows about 2 ft. in height, and bears rosy-purple flowers. This generated the first double form, known as *Clarkia elegans fl.-pl.* From the rose-coloured single kind of this strain has also been selected *C. elegans rosea fl.-pl.* From these double kinds have been obtained two splendid varieties, viz., Purple King (deep purple) and Salmon Queen (salmon-pink), both having very large flowers that are freely produced on strong branching plants. These are remarkably effective border plants, and received first-class certificates at South Kensington in 1874. Another form is *Clarkia pulchella*, from North America, a kind which grows to a height of from 1 ft. to 2 ft. Of this also there are dwarf or Tom Thumb varieties. *C. pulchella* has magenta-coloured flowers, and from it have been selected forms having double flowers of the same hue; also rose and edged flowers. The third distinct kind is *Clarkia integripetala*, a garden hybrid or selection from *C. pulchella*, a sort which has entire-petalled flowers, of which also there are Tom Thumb varieties. Out of this have

come the new double crimson and white kinds, both very fine and good. We have, therefore, now in all some nine or ten double Clarkias. A. D.

VEGETABLE CULTURE FOR MARKET.

RADISHES.—The first two crops of Radishes of the year are generally grown amongst fruit trees, if bush fruits or Roses do not occupy the ground. By sowing time, which is in November and December, the trees are leafless and pruned; therefore they do not offer much shade to the young Radish plants, but rather protect them from cold winds and severe frosts, and before the trees have made much growth in spring the Radishes are fit for market, and the ground when cleared of them is available for being planted with Lettuces or other plants that are best suited for a shady situation. Crops of Radishes to succeed those under fruit trees are sown in open quarters, in 6-ft. wide beds with alleys between them. After sowing the seed is raked in with wooden rakes, and afterwards slightly covered with fine soil taken from the alleys. The surface of the beds is then rolled, and in the case of early sowings slightly covered with long litter, which after the seeds have germinated is removed on every favourable opportunity, but immediately replaced on the appearance of frosty, snowy, or stormy weather. After the second week in February coverings are dispensed with if the weather is at all likely to continue mild for a time, as the plants have by this time become strong and better able to stand the cold. The litter is, however, kept in the alleys in case of emergency until all danger from frost is over, when it is removed entirely and converted into manure. Successional sowings are made in February, March, and April, in a manner similar to that just described, and in some cases during the summer, but except in moist situations Radishes do not succeed well in hot weather; therefore where such situations do not exist sowing ceases in spring, and recommences in August and September if the weather be at all showery. A good crop of Radishes during the summer is profitable, and especially so in dry seasons, when they are comparatively scarce. The ground chosen for them is usually that recently cleared of Celery, French Beans, Rhubarb, or Vegetable Marrows, which, after being deeply dug and heavily manured, is levelled and otherwise prepared to receive the seed. Sometimes Radishes are sown between Asparagus ridges, and in such positions they succeed remarkably well on account of the soil being deep and rich. The chief varieties grown are the red Turnip and Long Salmon. A few of the white forms of these two kinds are also grown, but the red varieties form the bulk of the crop. When Radishes are required earlier in the spring than they can be obtained from the December outdoor sowing, they are obtained from frames placed on hotbeds, or trenches are dug out and filled with manure, on which a little soil is placed, and after sowing, the beds are covered over with litter. In March the first outdoor crops are usually ready for market. The largest roots are in all cases pulled first, the others being allowed to remain until they also become marketable. When lifted they are tied in fan-shaped bundles, each consisting of about a dozen roots, with bast or a thin withie, and when washed they are placed in baskets for market. Women, who usually perform this operation, are either paid so much per day, or receive from 1½d. to 2d. per dozen bundles, and at these prices, although they seem small, when there is full work they earn from 5s. to 6s. per day. Birds are the worst enemies with which the Radish grower has to contend, and when large quantities are grown it is found necessary to employ boys to scare them away, otherwise they would devour all the seed, and even pull up the young plants in order to obtain the husks which adhere to the young leaves. In May and June Turnip

Radishes are so plentiful as to be brought to Covent Garden in waggon loads.

CORN SALAD or LAMB'S LETTUCE.—This plant, which is often called "Mache," is grown to some extent by market gardeners. The seed is sown for succession crops from August to October, the result being a supply from October till spring. There are two kinds grown—the Round and the Regence; the former is considered the best for winter use, but it runs to seed earlier in spring than the latter kind, therefore the Regence is sown in October for a supply after the Round kind has run to seed. The land on which the seed is sown is of a rich character, and in many cases it is sown broadcast among winter Onions or some similar crop for which the land has been liberally manured and otherwise well prepared. No more preparation is needed beyond raking the surface before and after the seed is sown. In gathering, the plants are pulled up by their roots, washed, and sold amongst mixed salads in small punnets. Most growers save their own seed, which is found to be better than that which can be purchased. For this purpose a bed is specially prepared, levelled, and made fine on the surface, after which it is rolled or otherwise pressed down firmly. Good plants from the general sowing are then selected and planted thickly, and the bed is afterwards kept free from weeds. In summer the seed which ripens is allowed to fall on the bed, after which the old plants are pulled up and the seed is carefully swept off the hard surface and placed in water to separate it from the soil, which sinks to the bottom. The seed is then dried gradually in the sun and put in bags and into a dry place, and under such conditions it will retain its vitality perfectly for several years. Corn Salad is not considered of itself a paying crop, but when sown amongst other crops it takes up but little room and therefore in such cases may be considered to be fairly remunerative.

MUSTARD AND CRESS.—These are grown to a large extent in beds made on the floors of Vineries, a portion being sown and a portion cut every other day. During February and March the floors of such Vineries remind one of a verdant pasture, so green and so healthy do the crops of Mustard and Cress in various stages of growth appear. After sowing, a good watering is given, and the beds are covered with mats until the seeds have germinated, when they are immediately removed. The Mustard and Cress are cut when they attain a height of $1\frac{1}{2}$ in. to 2 in., a long-bladed knife with a crooked handle being used for the purpose. With this implement in one hand the operator cuts as much at a time as he can hold with the other, which is about as much as will fill a punnet; he then deftly takes the cut material up with both hands and places it in an upright position in the punnet. So precisely do practised hands perform this work that one would almost imagine the Mustard and Cress had been sown in the punnets. During January, February, and March Mustard and Cress fetch from 2s. to 4s. per dozen punnets, but later on they become much cheaper. Rape is often sold for Mustard. It is mild in flavour and, perhaps, equally wholesome; it is also stiffer, and keeps longer in good condition in a cut state than Mustard. On hotbeds out-of-doors, in temporary frames, and in warm moist borders, Mustard and Cress are grown in enormous quantities, some using as much as 500 bushels of seed in one season, and £2 or £3 worth of punnets per week while the Mustard harvest lasts.

WATERCRESS.—Of all esculents used as salads this is the most important, but in London market gardens its culture is limited on account of there not being suitable places for it. Watercresses are said to have grown in a wild state on the banks of the Thames and other places near London for many years before their culture for market was attempted on any-

thing like an extensive scale, and there being then little demand for them the supplies from these quarters were sufficient; but as they gained popularity in France, Prussia, and elsewhere, so the demand for them in London also increased, and beds for their culture were formed at Springhead and Northfleet, near Gravesend, as far back as the beginning of the present century. What quantity of Watercresses is now consumed in the metropolis it is impossible to tell, but Mr. Horace Mayhew calculated that 14,958,000 bunches were sold in the course of 1851. Of this amount the street hawkers alone disposed of £13,949 worth. On an average they disposed of 5s. 6d. worth per week each, on which the profit was about 3s. 6d. This estimate of the Cress trade in London does not, of course, take into account the amount brought in directly from the country and disposed of in other ways. As the population of London has so vastly multiplied of late years, the amount now consumed must be much greater, and is daily on the increase, as people are beginning to learn the true value of this wholesome esculent; although the calculation, as just stated, was made early in the present century, Springhead Cresses are still noted for their superior quality. After these beds were started, and the produce obtained from them was found to yield remunerative profits, similar places were soon made where suitable situations existed round the metropolis, and it is estimated that there are no less than 10,000 bunches of Watercresses disposed of in London daily. Large supplies are now obtained from Waltham, Cheshunt, Uxbridge, and other low-lying places near the Great Eastern Railway, and the annual amount realised by growers for London alone is very great. The space at Springhead allotted to Watercress culture is about three acres in extent, and consists of a winding ditch varying in width from 6 ft. to 20 ft. The supply of water is furnished by numberless springs of fresh clear water, which bubble out near the banks of the stream in various places, and form themselves into a little rivulet. The water contains a good deal of iron, and on the sides of the Cress-beds, where it is somewhat stagnant, the Cress assumes a much more unhealthy colour than that in the middle of the stream. The Cress-beds at Springhead lie in a warm sheltered valley; the sloping banks on either side the stream, which appear to be exceedingly fertile, are covered with fruit trees, such as Apples, Plums, &c.; and Lettuces thrive well near the water. The Watercress is re-planted yearly, generally in August and September, and sometimes in spring. Tufts of the roots are taken up and pulled apart, and planted in rows about 1 ft. apart, after which they are trodden or rolled down, with a view to induce the roots to take quickly. The water is just deep enough to cover the roots, and when fully grown the young shoots in summer represent a miniature meadow of healthy green Watercresses. Cutting is practised three times a week, as many being cut at a time as the markets require. Cutting the Cress is performed by men, who with leather boots to knee, walk in the beds, and with a long knife chop off the most forward of the Cress about 9 in. long, and place it in baskets in such a manner as to allow of a circulation of air through the baskets, in order to prevent the Cress fermenting. Before being placed in the baskets the Cress as cut is dipped overhead in the water, which keeps it fresh until it gets to London, when the purchaser afterwards keeps it well wetted as long as it remains in his possession.

CHICORY AND WITLOOF.—Chicory, though a useful winter salad plant, is not grown so much near London as one might expect it to be. Nevertheless, when taken up in winter and forced, it furnishes an excellent salad. The seed is sown in drills 18 in. apart in a light open situation. When the seedlings appear they are thinned so as to be left 9 in. apart. In

winter the roots, which resemble those of a Parsnip, are lifted and placed in a warm corner in the dark, when they soon throw up a large white crisp head. Sometimes the seeds are sown in heat, and when the plants are 4 in. or 5 in. high they are kept in the dark under straw or mats, and, when well blanched, are cut and placed in small punnets for market. Witloof, which is closely allied to Chicory, is likely before long to become a good market salad plant, on account of its easy culture. Seeds of it are sown in June in deep well-manured soil, and when up the young plants are thinned to 6 in. apart. Early in winter the plants are lifted as required, and after having their leaves cut off near the crown they are replanted thickly in trenches 12 in. deep. These trenches are then filled up with litter; in a month or so the crowns start into growth, and when 6 in. high, are white and crisp, and ready for market. When better known this plant will no doubt be more largely grown than Chicory, on account of its superior quality.

DANDELION.—This is not grown to any great extent, although in the spring it may be seen in the market in a blanched state in the form of small plants with their roots attached. It is sown in beds and blanched by being covered up for a few weeks previous to being dug up.

HERBS.—All kinds of herbs are extensively grown in market gardens between fruit trees and on spare pieces of ground not available for other crops. The principal supply of herbs for distillation and drying purposes is grown at Mitcham in Surrey, and in Hertfordshire—indeed there probably are within 30 miles of London upwards of 1000 acres of land devoted to herb culture. Nearly all herbs are bunched and sold in a green state, and taking up, as they do, little room, they travel to market along with other things and are in some seasons very remunerative.

SPERMINT AND PEPPERMINT.—These are largely grown both for distillation and drying, particularly the latter; near Mitcham many acres are occupied by it. The roots are planted in the first place 1 ft. apart each way, and at the end of the two following seasons it is ploughed in, and afterwards kept clear of weeds by constant hoeing. In August the green stems are cut and taken to the distillery. The culture of Spearmint is chiefly confined to market gardens round Fulham, Gunnersbury, and Isleworth. Mr. Humphreys and Mr. Dancer, of Fulham, have both large pieces of ground devoted to it. The dampest piece of ground is usually selected for Mint if it is to be a permanent plantation. The roots are planted in rows 1 ft. apart, and the space between them is intercropped during the first season, but afterwards the ground becomes such a mat of roots that intercropping is impossible. During the Pea season enormous quantities of green Mint are disposed of in London, and early in spring when Mint sauce is in demand some growers devote large ranges of glass pits to its culture. Mr. Elliot, of Fulham, has several long ranges of heated pits which are planted with Mint roots in succession, to yield a good supply from early in the year until green Mint becomes plentiful out-of-doors. During severe winters this crop is a fairly remunerative one, but in mild seasons it sometimes happens that it can be had out-of-doors as soon as the last pit comes into use, and thus the time and labour of growing it under cover are lost.

SAGE.—This is not in such general demand in a green state as Mint, but in nearly every market garden a plantation of it may be observed in some out-of-the-way corner, where the roots often stand undisturbed for years. At Mitcham, however, large areas of land are devoted to its culture, and new plantations are frequently being made, it being considered under favourable circumstances a fairly remunerative crop.

Both the red and green leaved kinds are grown. Young plants are obtained by dividing the old roots in spring; they are inserted in rows from 1 ft. to 2 ft. apart each way, after which, if they continue in a thriving condition, no further attention is paid to them until late in summer, when the stalks are all cut off, tied in bunches, and disposed of at once. When blanks occur in the rows through the plants becoming sickly, the whole plantation is broken up and replanted.

PARSLEY.—This is grown to a large extent in some market gardens, whilst in others none can be found. The seed is sown in successional batches from March to August in rich soil, and generally where the plants are to remain, transplantation being considered detrimental to its producing good foliage; it also induces the plants to run to seed sooner than they otherwise would do. When up, the young plants are thinned out to a proper distance apart by means of hoes, and some growers protect a large bed of it during winter; but, as a rule, this kind of treatment is not considered sufficiently remunerative to be carried out on a large scale.

THYME.—The green and golden leaved varieties of Thyme are grown in spare places in market gardens; by some growers the latter kind is considered to be the best, because it grows better than common Thyme. The roots are divided into small pieces and planted between fruit trees, or as edgings to borders, where the soil is firm and solid—positions in which they succeed well and yield abundance of tops for bunching for market.

CAMOMILE.—This is a crop extensively grown at Mitcham, many acres of land there being occupied by it. In March old worn-out plantations are broken up and the plants divided into small rooted pieces. These are planted in well-prepared ground in rows 2 ft. apart each way, the intervening spaces being cropped with Lettuces or other esculents, which can be quickly got off the ground. It is, however, not an uncommon practice to plant Camomile plants as thickly again as those just mentioned, and afterwards to thin them out to the required distance asunder. As the blooms expand they are picked off by women, who receive 1d. or 1½d. per lb. for gathering them, a process which is continued as long as sufficient flowers are produced to be remunerative. When gathered the flowers are laid out in a shady but airy place to dry, after which they are put into canvas or paper bags and disposed of.

SQUIRTING CUCUMBERS.—These are grown for distillation alone, which is usually done by the growers themselves. They are raised from seed, sown in frames similar to those of Vegetable Marrows or ridge Cucumbers. About the end of May they are planted out-of-doors in light rich soil, in rows from 4 ft. to 6 ft. apart each way. The fruits are gathered before they are fully ripe, a condition in which they are liable to burst, and thereby become useless.

WHITE POPPIES.—These are grown at Mitcham on rather a large scale. The seed is sown in rows 2 ft. apart in spring; when up, if necessary, the plants are thinned out a little, and the ground is kept free from weeds, but beyond these operations no other attention is paid to them until August when their seeds are ripe. The heads or capsules are then carefully gathered, placed in bags, and disposed of to chemists and herbalists.

LIQUORICE.—This is not so extensively grown now as formerly, the expense incurred in its cultivation being such as to render it at times anything but a remunerative crop. Still large tracts of land at Mitcham are devoted to it. Ground intended to be planted with Liquorice is heavily manured, trenched, and thrown up in winter in rough ridges. In the

spring following the ridges are levelled, and the ground is marked off into drills 3 ft. apart and 4 in. deep. In these the sets (consisting of small pieces of the old root-stems each containing an eye or two) are planted. During the first year and a half after planting the ground is intercropped with Lettuces, Coleworts, &c., but after that the Liquorice requires all the room. In the autumn of each year the matured stems are cut off close to the soil, and the ground between the rows is forked over and, if need be, manured. The crop is usually lifted in the end of the third season after planting and the labour and expense incurred in this operation are very great. On this account growers seldom lift Liquorice themselves, but sell it as it stands, leaving the purchaser to harvest it. In order to extract the roots, which penetrate deeply, it is necessary to dig out a deep trench close alongside of the first row, and then by the aid of steel forks or ropes the roots are extracted. If the roots be not required for use at once they are stored away in sand or earth pits like Carrots, Beet, and other root crops.

BORAGE.—This is grown in temporary frames out-of-doors for supply during autumn and winter, and for spring use seedlings are raised in heat and transplanted into glass-covered frames, which can be easily removed when the weather is sufficiently mild to admit of the plants being exposed without injury. It is sold chiefly to hotel keepers for making claret-cup.

CREEPERS IN WINDOW BOXES.

WINDOW gardening has of late years made great progress, and one needs no other evidence than a glance at the windows of rich or poor in town or country to see to what perfection plants may attain in boxes, and how well they repay the care and attention bestowed on them. But while the majority of subjects grown require to be inside the windows, there is also a hardy class of plants suitable for growing outside in cases in which plants inside would not be admissible, or would interfere too much with internal arrangements. We have here for all the upper rooms of the mansion slate window boxes resting on iron brackets, and an ornamental wire trellis encircles each window, to which the permanent creepers are trained. I should also add that we have iron rods a few inches above the edges of the boxes, that make a neat looking balustrade, and support the dwarf plants in pots, which in such positions might otherwise be blown down. These dwarf plants are varied according to the season; but the climbers, to which I am desirous of specially referring, are permanent. For spring we use hardy bulbs such as Snowdrops, Aconites, Crocuses, Hyacinths, and Tulips; surfacing the ground with Forget-me-nots, Silenes, Arabis, Aubrietias, &c.; when these fade they are removed, and are replaced by a wider range of plants, such as taste may suggest. We use Ivy-leaf and other Pelargoniums, Lobelias, and Golden Feather Pyrethrum, varying each window as much as possible. For the winter season nothing equals very dwarf shrubs, such as *Euonymus*, *Thuja anrea*, and dark-leaved *Berberis* in the form of sturdy dwarf bushes about 1 ft. high. These look cheerful during all kinds of weather.

The climbing plants which I find most suitable for our purpose are variegated Ivies, which keep their colour better than when they have much root room, and also golden variegated Honeysuckle. The evergreen Honeysuckle is likewise an excellent plant for boxes, and the yellow and white Banksian Roses are extremely well adapted for window decoration, as is also *Jasminum nudiflorum*, which, although partially deciduous, makes up for that defect by having in a warm sunny aspect more or less of its bright yellow flowers, each as large as a shilling, expanded all through the winter. *Cotoneaster* and *Pyra-cantha*, neat close-growing plants that have cheerful berries in winter, are useful in boxes, and indeed I may extend the list indefinitely, but will only name a few which I have myself tried and found suitable for the purpose. During the growing season, in addition to keeping the plants well supplied with water, they should be frequently tied in as growth progresses, and some of the older wood should occasionally be removed, as the majority of flowering climbers do best when an annual supply of young wood is retained. When removing the dwarf subjects a little fresh soil should be added to the boxes, in order to maintain the vigour of the climbers that root so freely. Window plants would grow equally well in wooden boxes,

but they often decay just as the window gets properly furnished; slate boxes are therefore the most efficient and cheapest in the end.—J. GROOM, *Linton Park, Maidstone.*

PLATE CLXXXVIII.

AMARYLLIS O'BRIENI.

Drawn by CONSTANCE PIERREPONT

THIS lovely and distinct section of the genus *Amaryllis*, in which there are three varieties, is the result of considerable care and perseverance, extending over a lengthened period. The seed-bearing plant *Hippeastrum pardinum rubescens* (a variety of fine form, substance, and colouring) I could never succeed in setting with its own pollen, but at last I was recommended to use that of *Amaryllis reticulata major* (syn. *striatifolia*), and the result was that the flowers set, the pods swelled, and ultimately seed was ripened. On examining the latter a curious fact revealed itself; the seed on the *Hippeastrum*, which should have been flat and scaly, had, through using the pollen of *Amaryllis reticulata*, become so changed that it resembled large, somewhat thick, jet black grape seeds, rather than those of a *Hippeastrum*. Apropos of the change of form and colour of seeds through the influence of foreign pollen, I may mention another case: I once crossed *Amaryllis reticulata* with pollen of *A. procera* (a blue-flowered species), and the seeds that resulted were quite round, and as large as small peas. Seedlings of *Amaryllis O'Brieni* having been obtained, we imagined that all difficulties had been overcome; but that was not the case, for during the first three years they did not seem to increase at all in growth, and were indeed many times even on the point of dying; but whenever that was apparent they were turned out of their pots, and repotted in good fresh compost, in which they revived. At the expiration of the three years they however began to grow vigorously, and soon flowered; and since then they have proved themselves to be even more robust and more free-flowering than most other *Amaryllises*; indeed, we have never lost a bulb of this variety.

Amaryllis O'Brieni, like *A. reticulata*, should be grown in a warm house and not put away to rest along with the deciduous *Amaryllises*; on the contrary, it should be watered, even after the foliage has died off; it should be potted in a mixture consisting of half turfy loam and half peat. It generally flowers twice a year, is very fragrant, and lasts an incredibly long time in bloom, a property possessed by many plants which refuse to bear seed.

To the section in which *Amaryllis O'Brieni* may be placed, and which includes plants that grow best without being rested, belong the following, viz., *A. reticulata*, *A. O'Brieni*, with its varieties *delicata* and *rubescens*, three hybrids raised between *H. pardinum rubescens* and *A. reticulata major*; also *A. Henry Little*, a cross between *A. picta* and *A. reticulata*; *A. vittata striatifolia*, raised between *A. vittata* and *A. reticulata*; and *A. Pirloti*, raised between *A. gandavensis* and *A. reticulata*. All these have white bands down the middle of the leaves.

JAMES O'BRIEN.

[Our plate was prepared from a plant which flowered in Messrs. Henderson's nursery, Pine-apple Place, Edgware Road.]

Shortia galacifolia.—This highly interesting and rarest of North American plants is now in blossom in one of the greenhouses at the Botanic Garden, Cambridge, Mass., where it is an object of great attraction. It is a sweet little plant, not showy by any means, but a welcome garden Alpine. It is about 4 in. high, with Galax-like leaves, both as regards form and colour, and pure white bell-flowers, borne singly on stems 3 in. high. In 1778 Michaux discovered a *Pyrola*-like plant in the mountains of North Carolina, and secured the specimen, which was in fruit but not in flower, for his herbarium. Beyond that specimen, not another vestige of the plant, dead or alive, was known to exist till last year (1878), when it was re-discovered growing on a hillside in North Carolina, and specimens were then sent to the Cambridge Botanic Garden. Long before its re-discovery it was earnestly but unsuccessfully hunted for by Dr. Asa Gray and others; and even now so much importance is attached to the long-sought mountaineer, that a special company of botanists from here are to visit it in its native wilds as soon as its flowers open in the spring. A nearly-allied species, namely, *Shortia uniflora* (*Schizocodon uniflorus*), was discovered not long ago in Japan.—WILLIAM FALCONER. [The imperfect specimen of this plant preserved by Michaux was first found in examining the herbarium of that author by Dr. Gray in 1839, and, notwithstanding its imperfection and the fact that no other plant of the kind could be found after diligent search, Dr. Gray ventured to designate and describe it in 1842 as a new genus.—*Country Gentleman.*]

AMARYLLIS O'BRIENI

GARDENING FOR THE WEEK.

Flower Garden.

Auriculas.—Letters from the north state that "Auriculas are looking remarkably well." Mr. Simonite, of Sheffield, writes, "It rains every day; we have high winds, and the nights are bitterly cold, nothing does well but Auriculas." Now just a hint as to the green healthy appearance which Auriculas now wear. It certainly shows that the plants are healthy, but it is just possible that over-uxuriance may induce an autumn bloom, and that the plants may not winter any the better for it. They are taking a short summer's rest at present, and it is well to avoid any undue excitement. Keep the frames cool and draw off the lights always except when there is some danger to be apprehended from rain; do not water unless the plants really require it. I am alluding to specimen plants. In the case of seedlings and offsets the best way is to keep them growing as freely as possible. Water freely and keep the lights over them at all times, potting the plants as they require it. It is satisfactory to hear that many of the northern growers are raising seedlings. One of them, I am told, has thousands from good crosses. It will not say much for our intelligence in this direction, if we cannot surpass George Lightbody, Smiling Beauty, Glory, Freedom, Colonel Taylor, &c., which have been in cultivation before most of us were born. At any rate our florist forefathers have by their skill and zeal brought Auriculas up to such a high standard of excellence, that it is difficult indeed to equal, much less to surpass, the results obtained by them.

Carnations and Picotees.—Within the last ten days or so I visited two gardens in London, one a large public one, where I saw some half-dozen men attending to a few beds, on a small space, geometrically arranged and filled with Sedums, Feverfews, and Alternantheras. The other was an amateur's garden, which he managed himself; it was full of beautiful Carnations and Picotees, I may say thousands of them, and I was tempted mentally to ejaculate "Look on this picture and on that." Though carpet beds are fashionable is it fair that all the space and all the labour should be given up to them? Beds of seedling Carnations can be obtained at a very small cost, and they are emphatically a town flower. Seedlings should now be pricked out on a level piece of ground, made smooth by sifting some fine sandy loam over it. Prick the plants out about 3 in. apart, to be ultimately planted at distances of 12 in. from each other.

Dahlias.—In some districts these are not yet planted out, and no wonder, for cold cutting winds and dashing rains have been making sad havoc amongst such as have been so planted. A note from Manchester last week informs me that a hail-storm cut and bruised their leaves in such a way as to utterly destroy them. Our own, planted in a sheltered situation, have not suffered much, and are growing freely; some of them have thrown out too many side growths, but we have removed all except three or four and the leading one. I trust those who have not put their plants out have potted them into sufficiently large pots, so that the plants are not root-bound; they ought certainly to be out now. Slugs are a great nuisance this year, but they must be destroyed by hand-picking, dusting the ground with soot or quicklime, or anything likely to kill them. Earwigs have also appeared, but these can be secured by placing Bean stems (open at both ends) amongst the plants; the enemy shelters in them at night, and can easily be dislodged and killed next day.

Pinks.—These are now coming into flower; their blooms are of full size and well laced, and the plants are now making good growth. If pipings have not yet been put in, no time should be lost in doing so.

Pansies.—It is interesting to learn that this useful flower is becoming popular, and also that a special exhibition is devoted to it. There does not seem to be much danger of any of our fine hardy plants going out of cultivation. Little good can be done by means of the hoe amongst Pansies now; pick out the weeds, however, by hand, and peg down the shoots, removing, at the same time, all superfluous growths.

Polyanthuses.—It is questionable which is the best time to pot these, viz., July, August, or September. Growers about Newcastle-upon-Tyne are very enthusiastic as regards the culture of Polyanthuses, and one of the best of them writes to me to say that the end of July is the best time to re-pot; others say August, and others much later. It seems feasible that the best time to re-pot is when the plants start into growth, which they do in July, and I should suggest potting at that time so that the plants may be well rooted before winter. Let the soil be rather heavier than that recommended for Auriculas. Seedlings should be planted out in the place where they are to flower as soon as it is convenient to do so.—
J. DOUGLAS.

Stove.

The late sunless spring has had its effect on plants under glass, the growth of which, should the temperature have been kept by fire-heat to anything approaching that which would have existed with the ordinary amount of sunny weather we have through April, May, and June, will in many cases have a greater tendency to the production of wood than the formation of flowers. Consequently, most summer-blooming stove plants have been later in flowering than I ever recollect seeing them, and with those that naturally bloom in the later months the condition is similar, to counteract which dispense with shading, as far as possible; give a little more air during the day, even if the weather continues such as to necessitate some addition of fire-heat to admit of this, without which the shoots have a disposition to keep on extending to an undue length before the flowers are formed. This especially applies to late-started Allamandas, Aristolochias, Dipladenias, and the like. Stove plants, unlike others grown in a lower temperature, can scarcely be said to have any particular season for potting, and where any, either large or small, give evidence of requiring more root-room, there need be no hesitation in giving this, even with most plants that are forming flowers or even in bloom; but in all cases where potting is carried out with plants in an active condition of growth, as these necessarily now are, there should be no disturbance of the roots more than requisite to remove the old drainage material. Should the weather become hot the small diminutive yellow thrips, so minute in size as to often escape detection by those who have not had much experience with this class of plants, is almost certain to make its appearance on such plants as Allamandas and Crotons, both of so crude and poisonous a nature that it has always been a mystery to me why this insect should prefer their juices for its food to those of other plants. With this thrips fumigation is completely useless; it gets down into the points of the shoots to the very base of the young, newly-formed leaves, where there appears to be enough stagnant air to prevent the smoke entering. A continual application of the syringe is the only means I have found of keeping it in check; weak Gishurst will destroy all it comes in contact with, but it increases so quickly and is also so agile that if you move a plant with a view to dipping or washing it, half the insects appear to get on to the adjoining plants before it is possible to succeed in getting the mixture to touch them. For this reason I have found soot water the best remedy; it may be prepared and used in a clear state much as in the case of lime water when applied to the soil for the destruction of worms, or it may be syringed on to the plants with a little of the soot actually stirred in with it, allowing it to remain on for a few days. The latter method I have sometimes found the most effectual, as this with all other insects has the greatest aversion to the actual presence of soot; a syringing with soapy water and afterwards with clear water will remove any trace of the soot from the leaves. Where many stove plants are grown, particularly of large size, and especially climbers, it will during this and the next month require constant attention to keep insects in check, without which it is useless to attempt the cultivation of many of the finest subjects we possess that need heat more or less continuously to grow them. I feel the necessity of frequently pointing to keeping plants clear from these animal-parasites, the preventive measures against, and destruction of which, occasion considerably more than half of the whole amount of labour required to keep stove or intermediate house plants in a condition capable of bearing that clean, healthy foliage, and producing bloom to the full extent of which they are capable, as wherever we see plants grown under a system that for a time leaves insects of any description to get to a head before anything is done for their destruction, the means employed usually result in the loss of half the flowers which they would otherwise bear.

Begonia fuchsoides.—This most beautiful and distinct old plant, so long left in comparative neglect, appears to be now more grown than it was. It is very easy to manage, although new hands at its cultivation frequently, whilst getting it to grow freely, fail in blooming it satisfactorily, the cause of which is generally traceable to its being kept in too close and moist an atmosphere. Plants struck from cuttings put in during the winter or early spring, kept growing on freely with the strong shoots pinched back once or twice, but not so as to interfere with its elegant branching habit, should now be in their flowering pots, which may be seven or eight inches in diameter; it is not well to overpot them, though it must be borne in mind that the larger the plants the more flower they will bear, provided the management is such as to induce the free production of bloom. It is frequently seen flowering in the summer, but when this is the case it may usually be set down to accidental treatment, as it is much more useful through the late autumn or in the spring. The plants should now occupy a small house or pit with their heads close to the roof, and have little or no shade unless absolute burning of the foliage takes place, plenty of air, gradually increasing it during the next month, and a drier atmosphere than some plants require; in fact, it is

well at this season to put this and any other subjects that need the air in a drier condition than the generality of stove plants by themselves.

Tabernæmontanas.—Where white, sweet-scented flowers are required for bouquets or similar floral arrangements, there are few plants that furnish them equal to these. In appearance they are much more delicate than a *Gardenia*, inasmuch as their crisped, irregular petals are less formal, the single and double forms respectively being not unlike the ordinary decorative white *Pinks* and *Carnations* with toothed petals. The reason why these plants have not been more generally grown is no doubt due to the disposition they have, when not properly treated, to drop their buds to a greater extent than *Gardenias* when these are kept in too moist an atmosphere; plenty of light, not too high a temperature, and more air and little shade, suit them best. Old plants that have been cut back after flowering last autumn or winter, partially shaken out, re-potted, and grown on, will ere this have bloomed or now be coming into flower, according to the way they have been treated. They are deserving of being grown in sufficient quantities to give a succession of flowers, and are most useful kept in moderate-sized pots; they are somewhat spare rooters, and do not like too much room. If a portion of the plants had their points nipped out in the spring they will come into bloom now; after they have done flowering large plants may be again cut in, as there is nothing gained by letting them get too large. They will root any time when half-ripened shoots can be had; cuttings of such put in now and grown on will bloom well in 6-in. pots next spring or summer.

Shrubby Clerodendrons.—These, including the fallax, *Kämpferi*, and fragrans forms, will in most cases have finished their first blooming; *C. fallax* and the others of similar habit make useful plants grown from seed, flowering with single stems the year after they are so raised. Where they are to be increased in this way, one or two of the bloom-stems may be allowed to remain and the seed to ripen; the berry-like seeds assume a black colour when ripe and part freely from the stem; they should then at once be sown either in small pots or a pan in sandy peat or loam—it is immaterial which. Plants that have bloomed will flower a second time later on, provided they are not headed back further than cutting out the bloom-stems.

Hoyas.—The bushy-growing forms of these, such as *H. bella* and *H. Paxtoni*, are much the most useful; they are excellent plants for hanging baskets; their delicate-tinted, waxy flowers are also beautiful for cutting. Unless where grown very cool they will by this time have completed their flowering; if a second bloom is required this can generally be secured by putting them in brisk heat, so as to get further growth which will flower in September, after which the shoots should be well shortened in, or they will get too long and straggling.

Impatiens Jerdoniæ and alba.—These most free-flowering, dwarf-habited plants are amongst the most interesting stove or intermediate house subjects in cultivation, but like many others that require some little difference in their treatment from the general occupants of these structures, we now scarcely ever see them, which is so far a mistake, as plants so totally distinct in their habit and general character as these are, independent of their individual beauty, tend so much to increase the interest attached to the collection with which they are associated. They are easily struck and just as easily grown, provided they meet with the treatment they require. To do any good with them, except in the very lightest houses with the atmosphere kept somewhat drier than an ordinary stove, they must be hung up close to the glass, where they will receive constantly all the light and air possible; if the pots or moderately deep pans in which they are placed are plunged in Moss in wire baskets, they are amongst the most beautiful objects that can be grown for use in this way, their singular-formed, almost transparent flowers being thus seen to the best advantage. If the baskets are draped with one of the pendant, small-leaved *Tradescantias*, so arranged they are very effective. The plants make comparatively little root and must not be over potted; the soil (either peat or loam) will do should be light, with plenty of sand and some crocks added; a little chopped *Sphagnum* will do no harm; they must never be over watered. The present is a good time for putting in cuttings—good-sized bits of the shoots, which, from their succulent nature, should be taken off and put in with a heel; they will do half-a-dozen together in 6-in. pots in a mixture of sand and peat or sand and loam, with a bell-glass overhead, but not closed down as is necessary with cuttings of most kinds, and the material should be only just kept slightly moist, or they rot, which established plants also do at the collar if treated in the way in which ordinary stove stock succeeds. But hung up as I have advised close to the glass, where if anywhere in the structure there will be motion in the atmosphere, the disposition to go off in this way is generally avoided.

Medinillas.—Medium or large-sized plants of these, especially the strong-growing *M. magnifica* and its erect-habited flowering

variety, to induce them to bloom freely need somewhat drier treatment than ordinary stove subjects so as to get them well ripened. Those that flowered early and were afterwards either cut in or not, will by this time have made considerable growth; if they have not already occupied the lightest and most airy position in the house they should be removed to this, shading no more than is found necessary to keep the leaves from burning, and gradually inuring them to less water at the root, yet not carrying this so far as to allow the plants to flag much, otherwise it will result in a loss of leaves. These fine distinct plants are frequently objected to, except for big houses, on account of their disposition to grow to a large size, but they naturally are such free flowerers that they will bloom in quite a small state, and from their being so easily propagated there need be no difficulty in dealing with them, as a few can be struck from cuttings each year, grown on, and flowered for two seasons, and then either headed down or discarded to make way for smaller ones. Cuttings will root at almost any time of the year in heat covered with a bell-glass, in their case not kept too close or the soil too moist, and where more plants are required these may be put in now.

Gloxinias.—For ordinary purposes these can be raised yearly from seed, and where a good strain of this is at command the plants from such a source are all that need be desired; but where it happens that more than usually fine varieties exist either from seed or otherwise it is well to increase them by cuttings made from leaves in the usual way. If the kind is scarce a single leaf will make three or four by notching the midrib at the underside, laying it flat on a pot or pan filled with sandy peat, $\frac{1}{2}$ in. of the top all sand, and putting on the surface of the leaf, over each incision made on the underside, a pebble about the size of a pigeon's egg to keep the cut parts in contact with the sand. They need to be kept slightly but not too moist; in this way they will form small bulbs in the course of the summer; but where the leaves of the kind or kinds to be increased are plentiful, larger bulbs will be obtained by putting each leaf in as a cutting, simply inserting the stalk end to the extent of $1\frac{1}{2}$ in. in the soil.

Torenia.—The favour with which the beautiful old *T. asiatica* was first received when it came into the country, but did not long retain, and the little estimation in which the later introduction of these easily-grown continuous-flowering plants are held may be accounted for by the fact that the unceasing demand for cut flowers (for which purpose they are of very little use) has compelled cultivators to limit themselves in a great measure to such things as will stand the longest in a cut state; yet this has been carried so far as to divest the majority of plant-houses of the interest attached to subjects of a distinct and handsome character. These *Torenia*s are equally suitable for growing in pots slightly trained in an erect position, or suspending in baskets and allowed to droop. I never found them to succeed so well the second year as they do the first after being raised from cuttings, as they frequently do not break well when cut close in after blooming, and unless so treated they become straggling and unsightly. If cuttings are put in now, choosing shoots that spring from the base not much disposed to flower, struck singly in small pots, which they will readily do, kept warm, moist, covered with a bell-glass, and shaded, and as soon after rooting as requisite moved into 4-in. pots, kept stopped, and in a position where they will grow slowly through the autumn and winter, they can then be potted on, and will make handsome decorative plants early in spring, blooming through the summer if well treated.—T. BAINES.

Indoor Fruit Department.

Pines.—As soon as the weather becomes sufficiently favourable to admit of the plants being placed in the open air for an hour or two, these will require a general overhaul both as to repotting, top-dressing, and cleansing of the pits and houses in which they are grown; all the heating material of whatever kind should be turned out bodily, in order to dislodge vermin and clear the drains, and where the bottom-heat is obtained from hot-water pipes, their coverings should be removed, and the pipes examined, freeing them from soil or other matter that might intercept in any degree the heat from being fully communicated to the bed. In replacing the plunging material, whether tan or leaves, caution will be required lest a too violent heat be engendered, a circumstance likely to occur if the bed be entirely composed of new leaves or tan; therefore it is best to mix some of the old material—about a third—with the new, a practice which will obviate all danger. After the plants have been placed in the new heating medium very little fire-heat will be necessary, though if the weather still continues sunless fires will have to be kept going to prevent a stagnant state of the atmosphere, as it is impossible to give air freely without fires, and unless air be now given liberally, the plants will become drawn, and the result will be the production of second-rate fruit. Fruits swelling off require abundance of water, but even at this period of the year it should be heated;

indeed, Pines in any stage of growth should always be supplied with water of at least the same temperature as that of the soil. Syringe overhead on warm sunny days when closing the ventilators, which should be done early in the afternoon, as the temperature may at this stage be run up to 90° or 95° with advantage, and so save night firing. The suckers obtained from the earliest ripened Queens will now be ready to shift into their fruiting pots, and in order to induce a stocky fruitful growth, give them plenty of room; as soon, too, as the roots have taken hold of the new soil, give air freely, and never allow them to want for water till growth is completed, and, as it were, requires to be consolidated, though even then anything like real dryness will be the forerunner of poor "shows." Pot another batch of the strongest suckers obtainable, which should have a moist atmosphere, and be partially shaded, but the soil should be kept on the side of dryness till the plants are rooted, when they may be treated in every way the same as established plants.

Vines.—The more than usually vigorous condition of Vines this season having their roots entirely in outside borders is calculated to teach us a valuable lesson, viz., that Vines require enormous supplies of water. We have during recent years been learning this, but a practical test is this season forced upon us, and to my mind, taking into account the lack of sunshine and warmth, the balance is decidedly in favour of the heavy rainfall. Of course, if borders are improperly drained opposite conditions may be expected, but speaking personally and from the state of the Vineries under my charge, I consider the abnormally heavy rainfall to have been beneficial, and this enforced lesson will lead to a still more liberal use of water on borders that are effectively drained. Rain-water tanks should be placed in all Vineries having inside borders, and as at this time of year the soil does not require to have warm water, the tanks should be emptied on the borders after very heavy rains, not only to economise the labour of pumping, &c., but because rain-water is in every way preferable to well water. Keep the surface mulched with 1 in. or 2 in. of stable litter, both for the sake of neatness and for that of inducing surface-rooting by the preservation of an equable state as regards moisture. Should a sunny period set in, which is much to be desired, scalding is sure to be prevalent; Lady Downes, Mrs. Pince, and Muscats are most liable to this occurrence, and the only preventive is to maintain a high night temperature, with the ventilators slightly open to prevent condensation of moisture, and during the day the ventilation must be as liberal as that given to greenhouse plants, till all danger from scalding is over, a period which usually lasts from ten days to a fortnight, according to the state of the weather. A season like the present upsets much of the usual routine, and that of dispensing with fires in July will not this season have to be regarded, as late Grapes, to keep well, should be fully ripe before the end of September, and without firing such cannot be the case this year. Husband sun-heat whenever it comes by closing up early, but aim by every means available to have the Grapes fully matured ere September is out. Keep lateral growths within reasonable bounds; if there is room for them on the trellis without crowding, let them remain, but not to the injury of large leaves, or the screening of wood and bunches from the light. Recently planted Vines intended for a permanency should have all the growth which they make left intact, but supernumeraries intended to fruit next season must be subjected to a moderate amount of restriction, by stopping the side shoots at the third or fourth joint from the main stem. Keep them free from red spider by syringing freely when closing up the house in the afternoon. Where Grapes are colouring, let air remain on night and day, but of course in proportion to the state of the atmosphere and temperature outside. The more time given Grapes to colour, the more perfect will it be. Do not scruple to water them freely even now if there be any danger of their suffering from drought before the fruit is consumed.

Peaches and Nectarines.—The remarks formerly made as to the necessity of well washing the trees and thinning out the shoots that have produced fruits as soon as all are gathered, are as applicable to succession as to early houses, and the borders need just the same amount of attention with regard to watering as during the earlier stages of growth. Trees swelling off heavy crops of fruit should be assisted by the applications of strong doses of guano water, if the borders are inside; if outside, sprinkle guano over them and the rains will wash it in. Continue to syringe with soft clear water till the fruit indicates maturity; then discontinue it, and decrease the atmospheric humidity. Pinch out the points of all shoots bearing fruit, and also the side shoots of the current year's wood intended for fruit-bearing next season. Expose ripening fruits to full daylight, without which good colour and flavour are unattainable. Gather the fruit before it is dead ripe, and it will keep longer and be brisker in flavour.

Strawberries.—In order to obtain satisfactory results as regards the forcing of these, attention must be paid to them all the

yearround. We finished layering runners for plants to fruit next season on the 2nd inst., and as yet we are gathering fruit from plants in houses, none being yet ripe in the open air. Our best runners are those that have been produced from the earliest forced plants, which were hardened off and planted in the open air on April 25. Good runners have also been obtained from young plants that were set apart for this purpose and planted last August, but these are not so early by at least a fortnight as those from the forced plants; hence, in future, arrangements will be made to secure all runners from the earliest-forced plants only. The runners will be severed from the parent plants as soon as they are well rooted, and will be at once potted into their fruiting (6-in.) pots. The plantation will then be cleared of runners, and the soil surface forked and mulched with 3 in. or 4 in. of manure, and then a good autumn crop of fruit will be rendered certain, at all events from Vicomtesse Hélicart de Thury, for this kind is quite as valuable for autumn fruiting as it is for early forcing.

Melons.—Provided the outlet is free, and there is no danger of any part of the border becoming sodden, give abundance of water to swelling fruit. A notion prevails that Melons require water at long intervals only, but though they often survive and even fruit under such treatment it cannot be called good cultivation, seeing that the foliage gets either eaten with red spider, or else smothered with mildew, and the fruit produced is, in consequence, flavourless; for unless the foliage keeps good and able to perform its functions till the fruit is perfectly ripe, good flavour is impossible. Therefore, after the fruit is set, the one great aim in Melon culture should be keeping the foliage in a healthy condition, and this cannot be done unless the soil is kept moderately moist throughout the whole of the growing season. Plant out a last successional batch, and any old plants that are being allowed to fruit a second time should be occasionally watered with a weak solution of guano water. Stop all laterals at the first joint beyond the fruit, unless there is plenty of space in which to lay them without overcrowding, in which case they may be left any length.—W. W.

Kitchen Garden.

In this district (North Hants) all vegetable crops are quite a month later than usual, but all, without exception, are looking well. From William I. we have gathered quantities of super-excellent Peas. Veitch's Ashleaf Potatoes are also excellent, but not a heavy crop; they require warmth. Dwarf Erfurt Cauliflower and Early London are both good. Asparagus has never been so fine or so tender as it is this year, thus showing what a moisture-loving plant it is. We have now discontinued cutting, and have given the beds a dressing of salt and guano in order to compensate in some measure for the excessive demands made upon them through the lack of other vegetables early in the season. Hoeing for the destruction of weeds has been impossible, owing to the constant succession of showers which we have had; weeds therefore abound, but they must be pulled up ere they seed or endanger the well-doing of the crops by causing a spindly growth. When weeding is done let the surface be broken by means of prong or cultivator in order to prevent it from craking should a dry period set in. Breaking up the crust will also conduce to the more kindly growth of the crop. As soon as early Peas and Potatoes are removed let the ground be prepared for Autumn Giant Cauliflower and early Broccoli, such as Snow's, Osborn's, and Veitch's Self-protecting. If well trenched for the Peas, Potatoes, &c., no other preparation will now be necessary beyond simply levelling and cleaning the ground, and giving it a sprinkling of guano or soot to be washed in by the rains. Ground cleared of Cauliflowers may be used for early Peas or for Spinach and Lettuce, each of which should now be sown in order to ensure a good autumnal supply. The practice of planting Broccoli and Winter Greens generally between the rows of Potatoes is not a good one, but where ground is limited it is sometimes unavoidable, as it is in our case this year, but as the rows of Potatoes are a yard apart no real harm will be done to either crop. Savoys, Kales, and Brussels Sprouts have all had to be thus planted, but late Broccoli will be planted on ground now occupied with mid-season Peas, Broad Beans, and Strawberry plants; meanwhile the plants are pricked out on a border with a north aspect, and will be transferred to their permanent positions as soon as possible. A good breadth of Early Horn Carrots should now be made on a warm, dry border; these small Carrots are much preferred to larger ones, and without much difficulty they may be had fresh from the ground all the year round. Sow Cabbages for the main autumn planting, and Coleworts for winter and early spring use. Lettuce, Endive, and Radishes should also be sown, the latter about once fortnightly up to the end of August. Black-seeded Bath Cos is a fine Lettuce for present sowing, being thoroughly hardy and well withstanding the autumnal frosts and rains. The weather has been too cold for Vegetable Marrows, ridge Cucumbers, and Tomatoes, none of which have yet made satisfactory progress, and there is no means of aiding them beyond keeping the surface

soil stirred and the growths well trained out and protected from the boisterous winds which we are having, and which remind us more of November than July.—W. W.

THE LIBRARY,

THE ORCHARD HOUSE.*

Of this work, begun long ago by Mr. Thomas Rivers and now carried on by his son Mr. T. Francis Rivers, the sixteenth edition has just reached us, in which is given the most recent experience in orchard-house culture at Sawbridgeworth. Mr. Rivers's first orchard house was built in 1850; since that time many have been erected in one form or another in different parts of the country, and all of them, we believe, have more or less answered the purpose for which they were intended. Nevertheless, some are still doubtful as to their utility, and for the consideration of such doubters Mr. Rivers publishes the following results produced in a house 100 ft. by 24 ft., the size only of a moderate Strawberry bed:—

Forty pyramid Peach and Nectarine trees, 8 ft. to 10 ft. high, each 2 dozen	=	960
Twenty-eight ditto 3 ft., each 1 dozen	=	336
Sixty-seven half-standards, 4 ft. to 6 ft., each 1 dozen	=	804
Twenty ditto large, each 2½ dozen	=	600
Fifteen ditto Apricots, large, each 3 dozen	=	540
Twelve ditto small, each 1 dozen	=	144
Six standard trees, Peaches planted out, occupying the space of 4 pyramid trees in pots, each 6 dozen	=	432
Or nearly 4000 fruit.		3516

The house from which these results have been obtained has been built about fourteen years, and has produced a like crop during all that time, many of the trees being twenty years old, so-called good and bad seasons having no influence whatever on the produce. Mr. Rivers states:—"I have little to add to the rules of cultivation, which must be in a measure stereotyped, but I have seen reason to somewhat modify the summer pinching, which I thought necessary at one time for all trees. I still think it is necessary for very dwarf cultivation, but if the house is sufficiently large for trees 8 ft. to 10 ft. high, I think that more latitude may be given. Pyramid trees, the most beautiful of all when well grown, do not require the close and incessant pinching requisite for dwarf bushes."

Of all fruit trees grown in orchard houses Plums, perhaps, succeed the best. We therefore extract the following on Plum tree houses:—"After some years of experience, I have found that Plums are very easily grown in pots. It is well known that Plum trees in our climate bloom so early in spring as to be much injured by our spring frosts; it may safely be asserted that a fair crop of Green Gages, away from walls, is realised but three years out of seven, even in the south of England, but two years out of seven in the midland counties, and seldom or never in Yorkshire. Now, I propose that for those who wish to grow a regular and certain crop of Plums without incurring a heavy expense, rough-built, lean-to, or boarded span-roofed orchard houses should be erected in some out-of-the-way corner of the premises, consisting of Larch poles, rough ½-in. boards, with two or three sliding shutters for ventilation; in fact, merely a glass-roofed shed on purpose for protecting Plum trees in pots while in blossom and setting their fruit. It is surprising with what vigour and beauty Plum trees blossom even in the rudest glass structure, and as the trees need not remain in the house longer than the end of the first week in June, for then all danger of severe spring frosts is over, they may be placed so close together that a house 20 ft. by 12 ft., with a path in its centre, will hold ninety-six trees, forty-eight on each border. The trees may be planted in 13-in. or 15-in. pots, and treated exactly as other orchard-house trees, with this difference—all the trees having young fruit should be removed from the house on June 7, and placed in rows or otherwise in the garden to ripen their fruit in the open air. The pots may be plunged in the soil one-third of their depth, but not more, for if the roots are too cold the fruit will suffer in flavour, and if the soil in which they are plunged be wet and cold, it should be drained or made porous, so that the water may pass from the pots rapidly; the top-dressing of manure must be most abundant. As a matter of course, the very late Plums must be ripened under glass, but all those varieties that ripen in the open air before the beginning of September may be placed there to ripen their fruit, which they will do perfectly; regular annual crops may thus be ensured if care be taken to thin the fruit properly. If too large a crop be extorted, the tree will take a year's rest. It is quite astonishing how prolific pyramid and bush Plum trees become in a few years, and, by merely pinching off the ends of all their shoots to three leaves, they soon form themselves into compact trees,

and very ornamental when grown as pyramids and placed in an avenue leading to the house for their summer quarters.

"The best varieties for this extended mode of Plum cultivation in pots are the Early Prolific, the Czar, Early Orleans, the Early Transparent Gage, De Montfort, Early Green Gage, Transparent Gage, Denniston's Superb, Green Gage, Angelina Burdett, Kirke's, Guthrie's Late Green, Reine Claude de Bavay, Purple Gage, the Coe's Golden Drop, the Grand Duke, and above all, the Jefferson, one of the most beautiful and delicious of Plums. These are for the desert, but, as in some climates it may be necessary to grow Plums in the same way for culinary purposes, I may as well give the names of a few good kitchen Plums, such are the Victoria and Autumn Compote, both large and excellent, ripening in succession, the Diamond, the Early Orleans, White Magnum Bonum, the Mirabelle, Prince Englebert, and the Sultan. The trees must all be removed to the orchard house the last week in October, top-dressed, watered, some hay placed over them to protect their roots from frost, and then kept dry all the winter. I may add that as Plums are coarse feeders I take the surface earth out in autumn to the depth of 6 in. at the side of the pot, sloping upwards to the stem, so as to be able to give them a large quantity of fresh compost.

"By those who wish to grow Plums under glass in large quantities, another very simple mode of culture may be practised—viz., planting a house with pyramids or half-standards, and removing them biennially to check their growth. Half-standard Plum trees are most prolific and very convenient to manage. One of our most skillful gardeners treats them in this manner, and finds that, after a few years, owing to the trees being every season loaded with fruit, they do not require removal as they grow very slowly. When cultivated as pyramids in the orchard house, they should be managed and pruned as directed for Apricots; they should, however, be pinched to three leaves instead of five as recommended for Apricots, and when cultivated as bushes, summer pinching to three leaves will be found by far the best method of pruning."

The book (crown octavo, consisting of 266 pages) is well printed, and contains several woodcut illustrations, and in addition to chapters on the different fruit trees suitable for orchard-house culture, it contains a good monthly calendar. M.

TOWN AND WINDOW GARDENING.*

THAT a large and exhaustive work might be produced under such a comprehensive title as that which has been given to this book, our own columns have from time to time proved. The importance of window gardening and town planting cannot be gainsaid, and it is an absolute duty of all who have it in their power to encourage a love of plants, especially amongst the poorer or working classes, not only for the sake of relieving the monotony of the exterior of rows of brick and mortar in our busy centres, but also, and more particularly, for the purpose of enlivening, beautifying, and making more attractive the too often squalid homes of our labouring people. Whether the book before us will fulfil the mission for which it is intended, and help to "inspire little children with a love of flowers," is, we think, doubtful, for it aims at too much—more, indeed, than a child or an uneducated mind can grasp. In such a book the principal endeavour should be to induce people to love plants for their own sake, for their general beauty or outward attractiveness. The "habits" of plants would here legitimately come in, but the "structure" and "uses" might well have been reserved; thus in considering a grain of corn in the first lecture on p. 7 we read that the "cells contain starch and a living substance called by a long and difficult name, *protoplasm*," which the authoress further states is "a most wonderful substance." As the authoress has evidently had the well-being of the citizens of our crowded alleys at heart, it would be ungracious to multiply faults; we may, however, be pardoned if we direct attention to one that may receive correction should another edition be called for. At p. 142, under the head of "Fine-foliaged Plants for a Room in Winter" we are told that *Dracenas* and *Bignonias* are members of the Lily family. We suppose the authoress intended to write *Begonias*, which are, however, as far removed from the Liliaceæ as the *Bignonias* themselves. But let us rather direct attention to some of the good points in the book as showing that the authoress has really good taste and the power to train young minds in the right direction. On the subject of leafless trees in winter she says, "I often think I admire them more without their leaves, because then you can see the shape of their branches which look so delicate against the sky." Again, Mrs. Buckton loses no opportunity in recommending to the notice of her hearers or readers the beauty of wild plants, or those generally considered not to be worth growing. Q.

THE INDOOR GARDEN.

PROLIFICATION OF NYMPHÆA RUBRA.

THE case of proliferation of which we are about to speak occurred in one of the hothouses belonging to the Museum of the Paris Jardin des Plantes in 1878. This phenomenon, so far as we know, has never happened before in plants belonging to this Order, once more showing how special characteristics are produced in plants, and the spontaneity with which they appear. We must remark, however, that this spontaneity should in no way surprise us, seeing that it is constantly manifested in all directions. No doubt it is the effect of the action of some unknown law, the results of which we are pleased to call "accidents," "anomalies," or "sports." Proliferation of this kind appears to be produced accidentally in a variety of genera, belonging principally to the Composites, especially amongst the Daisies and Marigolds, but which has rarely been seen in other Orders in which, as in the *Nymphæa*, the flowers are solitary. We have, however, a kind of proliferation in the old-fashioned Hose-in-Hose Polyanthus, to be seen in almost every cottage garden in the south of England. The *Nymphæa*, although it has been growing where it is for a lengthened period and flowers abundantly every year, has never hitherto produced anything but normal flowers. Last

CULTURE OF THE SCARBOROUGH LILY.

VALLOTA PURPUREA, the so-called Scarborough Lily, is too well known to need description. It is one of the few Cape bulbs—of which so many were formerly grown in English gardens—that have retained a hold upon public estimation. Appreciated, however, though it may be for its decorative value, it is nevertheless a fact that it is seldom seen grown to that degree of perfection which its merits deserve. This remark applies more particularly to large establishments, where it is when out of bloom too often relegated to some obscure corner, and consequently fails to obtain that amount of encouragement which it should receive. Such neglect is undeserved, and many plants now occupying prominent places in our glasshouses do not so well deserve them as does this Cape bulb. Amateurs and window gardeners are more apt to cherish it, and one often sees better grown plants of it in a cottager's window than are generally found in large gardens.

Although the *Vallota* will live and even bloom tolerably well under circumstances which would prove fatal to many plants, it nevertheless fails to develop its blossoms in perfection if not liberally treated. Single bulbs of it well grown in 6-in. pots are valuable for decorative purposes; but the true beauty of this plant is not seen unless it is grown in the form of large specimens. Like most bulbous plants, it requires to be seen in masses; the effect which it

Fig. 1.—Proliferation produced by a *Nymphaea rubra* (one-quarter the natural size).

Fig. 2.—Proliferation and budding of a *Nymphaea rubra*.

year, however, two flowers presented the phenomena shown in the annexed illustrations. Fig. 1 shows the stalk ending in a flower, which at first appeared to be quite normal, but in course of time five secondary peduncles, of which two were united along the whole of their length, began to develop, and finally budded and flowered, as shown in the illustration. This phenomenon closely resembles, nay, appears to be identical with, that seen in the familiar Hen and Chickens Daisy. Fig. 2 shows an analogous phenomenon to that which we have just described, but is even more complex. We shall watch this plant with attention to see if the same phenomenon is reproduced next year. Although we may somewhat justly consider this as exceptional and a monstrosity, we must remember that this fact is in no way contrary to the fundamental principles of evolution. The sepals, petals, bracts, stipules, &c., of a flower are after all only modified leaves, therefore we cannot be surprised if one or any of them be produced in or out of their usual order, according to the condition and strength of the plant.—*Revue Horticole*.

Tradescantia mundula.—This makes a good basket plant. It does not, I believe, often bloom, but I saw a large plant of it the other day in a greenhouse quite covered with delicate white blossoms, very like those of a myrtle.—A. P.

then produces is truly grand. What renders it especially valuable is the fact of its blooming at a time when the generality of plants are out-of-doors and when showy plants are especially desirable for the conservatory and dwelling-house. A very fine effect may be realised by placing a dozen good bulbs of it in a 12-in. pot. When thoroughly established each bulb will throw up a strong spike crowned with from five to eight handsome flowers, the effect of which once seen can hardly be forgotten. Without doubt, one of the main secrets in *Vallota* culture is to allow the bulbs to become thoroughly established. This plant appears to dislike frequent shifts, and never flowers so freely and strongly as when in a root-bound condition. The main point to observe is to supply plenty of food during the growing season; from the time the plants start into growth until they come into bloom they will derive much benefit from regular bi-weekly waterings of guano, soot, or manure-water of any kind. If the plants be placed in a saucer they may, with great advantage, receive in hot weather a little sub-aquatic treatment; not requiring much shade, and having the pots crammed with roots, which appear to possess exceptional powers of suction, it will be understood that means must be adopted to supply when needful an unlimited amount of moisture. By placing the pots in pans the best facility is afforded of giving them what they require; indeed this treatment would appear to be a fair imitation of the conditions in which this plant is found growing naturally. I have been informed that the bulbs are

mostly found growing in well-drained sunny positions, but where the roots only find their way into a damp sub-soil. In such situations, under the influence of a hot sun, they pass through a vast amount of moisture, thus enabling them to so solidify their tissues that a grand display of bloom is the result. I think that if we desire to grow this Cape bulb to perfection, we shall find that a maximum of heat, air, and moisture is necessary to ensure success. Many do not achieve good results in the culture of this really beautiful plant from the fact of not realising that they have to do with an ever-green.

The *Vallota* should never be dried off; as the winter advances the supplies of water have, as in the case of most other plants, to be diminished, but moisture at the root must never be entirely withheld. A certain amount of foliage should be left to draw up the sap, and start the bulb into fresh growth again early in the spring. Another important consideration is light during the winter months. I have invariably found that those bulbs which enjoyed a maximum of light during the dull months of the year flowered much the best. The bulbs being encased in leathery folds, there is a danger of water finding its way amongst them, and rotting the bulbs. If only a few drops of water trickle down into the base of the bulb and remain there in damp weather, rot is almost sure to follow, and decay progresses in such a rapid manner that the bulb is ruined in a few days. It is very vexatious to thus lose good bulbs. I have therefore made a practice of placing each plant for the winter in a saucer, by means of which sufficient water to prevent the bulb or foliage from shrivelling can be administered without having to moisten the surface soil. Where any quantity of bulbs are grown, a succession of bloom may be kept up by placing a portion of them in warmth in early spring, small plants forming the best of subjects for room decoration during the summer months. The gracefully-disposed flag-like foliage, and the bright star-like blooms, to which the arrangement of the heavily pollen-loaded anthers lend additional grace, contrast in the most admirably effective manner with Ferns and most other foliaged and flowering plants. With respect to soil the *Vallota* is by no means fastidious; loam or peat will suit it, a mixture of the two probably best fulfilling its requirements. A porous compost is however indispensable, as the roots, being thick and fleshy, cannot well exist in health in a soil of a close nature.

Propagation is so easy that no difficulty need be experienced in working up a stock. The bulblets which form around the old bulb need only to be taken off and inserted in some free sandy soil. This, indeed, is the best time to commence the formation of a specimen, as, if a dozen little bulbs are dibbled into a 4-in. pot, and are shifted on as they fill the pot with roots, never attempting to part or disturb the bulbs in any way, they will be found to make rapid progress, and a large plant will be formed in less time than would be the case if each bulb were grown on singly. The *Vallota* is known to be of a hardy nature, and it is probable that it would pass the winter in the open air in many parts of England uninjured. I should much like to know if any of your readers have proved it in this respect. It would undoubtedly grow and flower well in a well-chosen situation, and a little protection to ensure its safety would not be a difficult matter to arrange. Plants that ripen their seed in a low temperature are generally enabled to resist a considerable amount of frost. Now, the *Vallota* will perfect its seed in an average temperature of 45°, descending to freezing point at night. This I have proved, and I sowed by way of experiment the contents of a pod thus ripened, little thinking it would germinate, but, to my great surprise, every seed came up. I consider this circumstance very interesting, and I cannot call to mind any other plant which would ripen its seed in such a low temperature. When the cold weather set in the pods were but half swelled; they grew on during the coldest time, and perfected the seed in February. With the exception of *Cyclamen hederifolium*, I do not know of a parallel case. The seed of this species is formed in September, continues to swell during the winter, but does not ripen until the following summer.

J. C. B.

DEEP POTS FOR LILIES.

Not only are deep pots preferable for these, but they are also by far the best for all plants of a moisture-loving character, especially such as send their roots far down into the soil in the way in which most of them do. So convinced am I of the advantage of having moderately deep pots, that I have given up using those made according to the old measure, as although they may be desirable for a few plants, shifting from one to the other is rendered awkward. Besides being better adapted for plant growth deep pots take up less room, which is a great consideration, and more particularly so in nurseries where plants have to be packed and sent out in hampers, in which pots of the deep make travel with much greater safety than those of other descriptions. The great secret in growing plants well is to have a ball of earth that does not dry too rapidly, which in shallow pots

with fair drainage it is almost sure to do during the summer months' seeing that there is a large body of heated air continually acting above and below the pot, and which, in passing through the soil, necessarily robs it of its moisture. In a deep pot where the surface area is less, evaporation is not so rapid, and consequently the plant growing therein is more favourably circumstanced, owing to its being kept in a more uniform condition as regards moisture. There is no doubt that it is beneficial for the ball to become a little dry occasionally, as that tends to keep the soil sweet and healthy, but sudden alternations are to be avoided, as they soon tell unfavourably on the health of the plant. No plants perhaps show the desirability of using deep pots more unmistakably than Strawberries, which are not half the trouble as regards watering when in deep pots that they are when grown in shallow ones, and besides saving labour in this way, the yield of fruit is greatly in their favour, a result brought about through the roots being always in a moist medium. This enables the flowers to set and the fruit to swell more regularly than is possible when the balls get dry, for if once checked in their onward course, the cuticles of the young fruit become contracted, and if this takes place, they never afterwards make satisfactory progress. As the time for layering Strawberries is now at hand, I would recommend that a trial be made of deep pots, as a commencement, feeling sure as I do that any one who may use them will have reason to be satisfied with the produce of the plants which may be grown in them.

S. D.

ACHIMENES AND THEIR CULTURE.

WHEN looking through a small garden a few days since I was much struck with the healthy appearance and vigorous growth of some pots and pans of Achimenes coming on for exhibition. The Achimenes are excellent exhibition plants, and at some of the provincial shows held during the months of July and August they are invariably present in very fine form. Some of the earliest to be met with are at the exhibition of the Tunbridge Wells Horticultural Society, which is held on the first Friday in July, and they are always large specimens grown in pots or pans and laden with fine flowers. The Achimenes is such a useful and valuable decorative plant that it should form a part of the collection of plants in every place having a stove, and consequently a moist bottom heat at command. A good plan to start it into growth is as follows: Ordinary seed pans may be filled to within 1 in. of the brim with a light, fine soil, made up of two parts leaf-mould, one part loam and one part sand. The bulbs of the Achimenes can be placed on this soil about 1 in. apart and covered with $\frac{1}{2}$ in. of soil; then a gentle watering may be given and the pans placed in bottom heat, where they will soon begin to grow. When these have put forth shoots 1 in. or so in length, they should be potted off into 3-in. pots, placing six of the plants round the edge of the pot, using the same soil as before recommended, watering them by means of a gentle sprinkle with tepid water, returning them to the warm pit or frame, but plunging the pots in the fermenting material, as bottom heat is indispensable at this stage. In about two weeks the pots will be filled with roots and another shift will be indispensable. The pots require to be well drained, the size used depending on the dimensions of the plants; but a slight shift will suffice, so that the roots may find their way to the sides of the pots as soon as possible. In about a month it will be necessary to give the final shift, and this should be a pretty large one, still using the soil above recommended. The plants will now require to be plentifully supplied with water, watering in the evenings, as it is said that if water touches the leaves and the sun strikes them when moist they will become scorched and lose much of their beauty. Great care is necessary in giving air to the plants, and on no account should air be given both at the top and bottom of the pit at the same time, as the plants are somewhat impatient of cold draughts playing on them. When they begin to flower it will be necessary to shade them in sunny weather lest the flowers be injured by the action of the sun. When the plants are in full bloom and can be employed for decorative purposes, they should have a position in a stove or somewhat close house, and only when the weather is very warm and genial should they find a place in the greenhouse.

After the plants have gone out of bloom they should be allowed to die off gradually, and should be placed on one side for the winter where they are out of the way of harm from frost and not in danger of decaying from dry-rot. A first batch should be started into growth early in February, and others should be grown on afterwards to supply a succession of flowering plants.

The following will be found a good and useful selection of varieties: *Ambrose Verschaffelt*, *Aurora*, *Baumanni hirsuta*, *carminata splendens*, *Eclipse*, *Edouard Boissier*, *Harry Williams*, *longiflora major*, *Mauve Perfection*, *Meteor*, *Parsonsi*, *purpurea*, *Rollissoni*, *rosea magnifica*, *Stella*, *Unique*, and *Williamsi*.

R. D.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Disocactus biformis.—This somewhat singular and rare plant at first sight might be mistaken for an Epiphyllum, but it differs from that genus in being less dense, and in having the flowers, which are rose-coloured, more regularly distributed, and not always on the apex of the stem. It flourishes under the same treatment as that usually given to Epiphyllums, and, being a native of Honduras,

Disocactus biformis

it wants a considerable amount of heat. It does best as a basket plant. Many little varieties of this kind are lost through not being grown in a way which suits them best.—J. CROUCHER.

Azalea indica Empress of India.—This fine variety is of Belgian origin, and was raised by M. Van der Cruyssen, and exhibited by him at the Ghent Show in 1878, under the provisional name of Héros de Flandre. It has since then passed into the hands of M. Auguste Van Geert, of Ghent, by whom it is now being distributed under the name here adopted. The Empress of India will take rank amongst the finest of recent acquisitions. Its compact-growing habit and dark green foliage are all that can be desired, while its blossoms are remarkable not only for their size and substance, but also for their symmetry. They measure 4 in. in diameter, are perfect in form, the outer segments of the corolla well expanded, even at the edge, and fully displaying the tuft of numerous smaller petaloid segments which fill up the centre. The colour is a pleasing tint of rosy-salmon, feathering out towards the well-defined but narrow white band which borders each lobe, the upper segment being, in addition, blotched with a dense mass of deep crimson dots. The central petaloid segments are of the same rosy colour, and similarly bordered with white. We understand that this variety is, like most of its race, a free-blooming kind and of vigorous constitution, so that it may be looked upon as a valuable addition to the many fine Belgian varieties which have been recently introduced, and which have proved so important and valuable as decorative and exhibition plants.—*Florist.*

Hanging Baskets in Conservatories.—When well filled these form acquisitions in conservatories and plant houses, besides being available for indoor decoration. They should, however, bear some proportion as regards size to the spaces which they are to occupy, as small baskets suitable for drawing-room windows or plant houses would be quite out of character in lofty entrance halls, and still more so in spacious conservatories. Although as a rule baskets are filled with a mixed arrangement of flowering and trailing fine-foliaged plants—which is, perhaps, the best in a general way—yet where means are at hand for keeping up a successional display, very striking effects may be obtained by having only one kind of plant in each basket, filling them in pairs consisting of single varieties, as, for instance, at this season, Achimenes, Tropæolums, Ivy-leaved and zonal Pelargoniums, and Lobelias. For green-foliaged baskets various kinds of Ferns succeed admirably if kept moist and shaded, as does also that most useful of all plants for covering bare surfaces with a living carpet of green, *Lycopodium denticulatum*. But to give a full list of basket plants would make quite a catalogue; suffice it to say that to ensure success a tolerably rich friable compost, and above all copious supplies of tepid water after the plants get well rooted, are required. Stopping, training, and pegging down the main shoots over the base of the basket, also need attention in order to get all parts evenly covered; after that they should be allowed to grow naturally during the season.—JAMES GROOM, *Linton.*

THE FRUIT GARDEN.

LAYERING STRAWBERRIES.

For many years past we have always had a large number of Strawberry runners put into small pots by the end of June, but July will be well advanced before many of them are ready for this operation, as Strawberry runners, like most other things, are some weeks later than usual this season. However, they promise to be good when they are ready, and by a little extra care in layering, and good treatment afterwards, I have no doubt they will make as fine plants by autumn as in former years. Many only layer such Strawberry plants as are wanted for pot culture, but we layer into pots every plant which is required for planting in the open quarters during August and September; and, although it is a little more labour at first than only lifting them from where they have rooted and planting them again, it is a plan which secures much finer plants, which get established early in autumn, withstand the winter well, and produce fruit the following season. On this account I would advise all who purpose making a new plantation of Strawberries later on to take the first opportunity of preparing the plants for it by layering them into pots; 2-in. or 3-in. pots may be used for the purpose. They need not be new pots, but should be clean inside. A piece of charcoal, crock, or something of the kind should be placed at the bottom of each pot, which may then be filled up rather firmly with the soil. The latter should consist of fine loam and leaf-soil, Mushroom manure, or any old manure, in about equal parts.

When the runners have not rooted much the whole of the pots may be filled in the shed before taking them out to the plants, and each plant must be lifted and placed with its roots resting in the centre of the pot. A small wooden forked peg should then be taken and pressed into the soil, so as to catch the tendrils which connects the young plant with the old one. This holds the young plant firmly on the pot until it has taken a firm hold of the soil. But a different plan from this may be taken when the runners have rooted into the soil around the old plant. Instead of filling the pots at first, leave them empty; take them and the soil to the plants, and as each young plant is lifted by the roots, pot it in the ordinary way into the small pots without breaking its connection with the old plant. In this case pegs are not wanted, as the roots in the soil hold the plant firm enough. In both ways the plants should have a gentle watering through a fine rose as soon as the potting is over. In dry weather, when they cannot be watered as often as is required, it is a good plan to plunge the pots in the soil to the depth of 2 in. or 3 in., as they do not become so quickly dry in this way; and if they do get over dry they do not suffer so much through it. Where they can be frequently watered, however, they need not be plunged, but only placed level on the ground. The time for severance from the parent plant depends a good deal on what quantity of roots the young plants possess when layered. As a rule, all of them are ready at from two to three weeks. If layered now, well-rooted plants might be secured by the first week in August, and after being allowed to stand in the small pots for a few days when taken from the old plants, they may either be planted into the open quarters or potted into larger pots to fruit the following spring under glass. We generally layer many hundreds for both purposes annually with very satisfactory results. CAMBRIAN.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Large Strawberries.—I have just raised a Strawberry of the new President Lincoln variety which measured $11\frac{1}{2}$ in. in circumference, being, I believe, the largest of which we have any record in this country; has this been equalled in England?—H. HENDRICKS, *Kingston, N. Y., U.S.A.*

New Apple.—In the fine collection of winter specimens exhibited by Ellwanger & Barry at the recent horticultural meeting at Rochester was the beautiful Aucuba-leaved Reinette. It is medium in size, nearly round, striped and shaded with light red, and has a yellowish-white flesh, fine grained, with a mild, sub-acid, and very good flavour.

A superior Cherry, comparatively little known, called the Elenter Cherry, is, according to the *Journal of Horticulture*, cultivated on the shores of the Lake of Constance, notably at Lindau, Tettnang, &c. It is distinguished for its firm flesh, large size, and small stone, and is further noted for its superior travelling qualities. Being a late bloomer, a plentiful crop is invariably obtained, and as it ripens after all other table cherries are over, it is esteemed quite an acquisition.

Blighted Keswick Codlin Apples.—We have several trees of this free-bearing early Apple crowded with small dead branches that look as if paralysed or struck by lightning. I have noticed the same occurrence on many previous occasions, and more so in the case of this particular variety of Apple than in that of any other. Can any one explain why this variety should be so much affected? The blight generally shows itself just after the fruit is set; nevertheless, the healthy part of the tree generally grows away freely and perfects a good crop of fruit even in the most adverse seasons when other kinds are scarce.—J. G.

Late Forced Strawberries.—In a season like the present when Strawberries, like all other garden produce, are late in ripening, it requires an extra supply under glass to meet the demand that would in ordinary seasons be met by produce from open-air beds. We have at present (June 20) a fine crop ripe in cold pits on plants that were fruited in pots last year and planted out, as is ordinarily done after the forcing season is over. These may be relifted any time during spring, as the ball consisting of old roots and earth that will adhere to them will ensure their safety at any time. Even if in full bloom and if placed in pits as bedding plants or early Potatoes are cleared out, well watered, and kept close for a few days, they will produce an excellent late crop. They are not perhaps valuable in a commercial point of view, but when fruit for dessert has to be regularly supplied they will be found to be most useful.—J. Groom.

Selections of Hardy Fruits.—The present season seems likely to again remind us of the necessity of selection as regards open-air fruits; for, while the fruit crop this year is now generally put down as a partial failure, certain sorts are still bearing fair crops. For instance, among Pears we have fine crops on standard trees of Ashdown Park, Lammas, Swan's Egg, and a few other kinds. Amongst Apples, Keswick Codlin, Stones Apple, Graham's Russet, Golden Knob, and King of Pippins are producing good crops; and amongst Plums, the same may be said of The Dolphin, a sort largely grown now for market. This variety seems to have braved the season the best of all. I might multiply instances indefinite, but only give the foregoing in order to induce those who are contemplating planting to select from those sorts that appear able to withstand our very trying seasons and yet produce fruit to repay the cultivator.—J. GROOM, *Linton, near Mailsstone.*

Summer Pruning Peach Trees.—This is the best time for the principal pruning of Peach trees on open walls; in fact, if done now with judgment little winter pruning will be necessary beyond taking out any dead or worn-out branches. My own impression is that Peaches and other stone fruits, although impatient of the knife in winter, may be freely cut in with advantage during active growth. For this reason I cut out but little at the winter or spring pruning, either under glass or on open walls; but, taking the trees in rotation as their crops get to a safe stage for final thinning, I cut out all useless or barren wood and only retain that on which there is fruit, or such as is needed for producing bearing wood for another year. Peaches and Nectarines when in good health require to be disbudded, and thinned with a rather severe hand, as under favourable circumstances they make a surprising amount of growth in one season. Under glass there is not much fear about getting the wood well ripened, but on open walls undue luxuriance must be repressed. Gross, watery shoots should be cut out and those of medium strength laid in, far enough apart for all the foliage to get free exposure to light and air, as on its perfect maturation and strength of flower-buds depends next year's crop. A good heavy crop is the best and most natural way of diminishing superabundant vigour, and the most likely way of attaining that is to thin out the young wood well at

this season, so that what is retained may have the full benefit of what sunshine we may get to ripen it in good time.—JAMES GROOM, *Linton.*

NOTES OF THE WEEK.

The Curatorship at Kew.—We hear rumours as to changes in the curatorship at Kew. It is said that the situation has been offered to the superintendent of a well-known private garden in Scotland. The man in question is a most able gardener, but we doubt generally the system of appointing a private gardener, no matter how able, to the curatorship of a botanic garden, involving, as it always does, a wholly different set of conditions. Even the smallest botanic garden is so different in its contents from anything in private places that it would be little else than madness to place it in the charge of a person trained in ordinary private gardens. How much more so then must it be to place such a large and varied collection as that at Kew under the general direction of a person not having a life-training such as the curator of a botanic garden should possess. The fact that a man is a good cultivator in a private garden is no proof whatever that he would be so in a botanic garden. The things grown in each are wholly different. Mr. Smith, with his long training at Kew, is, we believe, generally admitted to be a very fitting man in all ways for the position, and therefore we hope the rumours to which allusion is made are without foundation.

New Sarracenia.—An interesting *Sarracenia*, raised in Messrs. Veitch & Son's nursery, was exhibited at South Kensington on Tuesday last, under the name of *S. formosa*. It is the result of a cross between *S. psittacina* and *S. variolaris*, and exhibits in a remarkable way the intermediate character of both parents. It is considerably taller in growth than *S. psittacina*, with its parrot's-head-like pitcher and lid of a pale green tint beautifully reticulated with crimson veins. It is, moreover, robust in habit, and in this respect is similar to *S. variolaris*.

Yellow Lobelia (*L. lutea*).—We have received from Messrs. J. Laing & Co., of Forest Hill, flowering specimens of this interesting species. It has much the same habit as that of some of the forms of *L. Erinus*; its branches, which are slender and trailing, are but sparsely furnished with leaves, from the axils of which are produced bright golden-yellow blossoms about the size of those of the ordinary bedding Lobelia. It is apparently very free both in growth and flower, and no doubt when it becomes better known and grown under different conditions it will prove very useful for bedding and other decorative purposes, as dwarf-flowering plants of this class are not plentiful. Mr. Cannell, of Swanley, has also submitted to us a bunch of flowers of this Lobelia which fully bear out the preceding remarks, the yellow hue of the blossoms being even brighter than in Messrs. Laing's specimens, and the flowers produced in greater profusion. Mr. Cannell informs us that he has planted it out in order to test its value as a bedding plant.

Perennial Larkspurs.—Perhaps the handsomest batch of flowers we have seen for a long time, either indoors or in the open garden, is one of *Delphiniums* in Mr. Joseph Stevens's garden at Byfleet. The wonderful beauty of the blues and purples in these flowers is quite beyond the art of the colour-printer. The beauty of *Gentians* is often talked of, but the fact is these *Delphiniums* surpass them in depth of colour and wonderful iridescence. If they were difficult to grow we should perhaps hear more about them; but they may be enjoyed by anybody with a bit of ground, and without the aid of any glass whatever. The wet season, instead of harming them in any way, has simply added strength and beauty to the flowering shoots, which it generally does in the case of hardy plants. We hope at another time to give a list of the best kinds in Mr. Stevens's collection.

Hymenocallis macrostephana.—We received this from two sources at the early part of the present year. First from Sir Philip Egerton, who had it from a Continental nursery under the name of *Paneratium fragrans*, and who noticed that it was quite different from the plant properly so called, which is a variety of *Hymenocallis speciosa*; and afterwards from Mr. Woodbridge, gardener to the Duke of Northumberland at Sion House, who has grown it for some time there. We have not been able, so far, to trace out further its history, or to ascertain its native country. Its nearest ally is evidently the Mexican *Choretis glauca* of Herbert, and the two together form a group midway between *Ismene* and the typical species of *Hymenocallis*, such as *speciosa* and *caribaea*, in which the corona is much smaller, and the free portion of the filaments proportionately larger. The flower is pure white and sweet-scented, and it certainly is one of the most valuable of all the *Paneratium* for decorative purposes. It flowers in February and March.—*Botanical Magazine*

A Field of Amaryllis.—Mr. Guiheneuf informs us that in the grounds of M. André Leroy at Angers there are at present two acres of Amaryllis in flower, mostly varieties of *A. vittata*.

Grass Seeds.—The Royal Agricultural Society has awarded Messrs. Carter & Co. a silver medal for the successful manner in which they have practically illustrated their system of laying down lawns and lands to permanent pasture.

Foxgloves.—We have received from Messrs. Caudwell, of Wantage, some beautiful varieties of Foxglove varying from pure white to the deepest purple and prettily spotted inside. They are amongst the finest we have seen.

Burnham Beeches.—These celebrated trees (says the *Court Circular*) are now absolutely secured, the Corporation of London having with great public spirit purchased both the trees and a quantity of the surrounding land for the sum of £12,000.

Cow Parsnips in Euston Square.—These gigantic umbelliferous plants now form a fine feature in this town Square. They are from five to ten feet high, and are bearing huge heads of flowers rising from tufts of very large leaves. Such plants are well suited for quiet nooks in town gardens, as they take care of themselves and spring up annually in abundance from self-sown seeds.

Prize for Seedling Roses.—We are requested to state that the prize offered at the National Rose Society's Show at the Crystal Palace by Mr. G. P. Hawtrej for three trusses of any new seedling Rose not in commerce, and for which there were no entries, may be competed for at the Society's provincial show at Manchester, on the 19th inst.

The Crops in Angers.—These are suffering just as much as here both in the garden and farm; so Mr. Guiheneuf, who has just come from Anjou, informs us. This is noteworthy in a climate where the Camellia is a common shrub, and where the Magnolia forms an evergreen boulevard. There is very little fruit this year; of Peaches there are none. The Peach in that region is grown against walls, as well as in the form of a standard tree.

The Australian Grass Trees (*Kingia australis*, and *Xanthorrhœa hastilis*) are growing vigorously in one of the greenhouses in the College garden, Dublin. The latter has recently flowered. They are as yet low-stemmed, but being now established are sure to do well. Their habit is unique—a graceful drooping head of glaucous sedge-like leaves, produced from the apex of a tree fern-like stem. The inflorescence of *Xanthorrhœa* is similar to that of a Bullrush in general appearance.

Begonia Reine Blanche.—This is without doubt the purest white-flowered Begonia which we have in cultivation. It is dwarf and compact in habit, and has deep green foliage and erect flower-stems about 1 ft. high, each bearing several blossoms of moderate size and of good form. We saw it in quantity a few days ago in the nursery of Messrs. Laing & Co., by whom it was raised. We also noticed a double white-flowered variety which will be a decided acquisition, as so far as we know no white-flowered double kind has before been raised.

Lilium Kramerii.—One of the finest examples we have yet seen of this charming Lily is in Mr. G. F. Wilson's garden at Weybridge. It is in a pot and is bearing eighteen flowers, sixteen of which are now fully expanded, and three of the stems have three flowers on each. The tallest of the stems measures 4 ft. from the rim of the pot. It is interesting to observe the many shades of colour which the blossoms of this plant assume, some being of a much deeper shade than others.

Pæonies at Tooting.—These gorgeous hardy perennials are now very gay in Messrs. Barr & Sugden's seed grounds at Tooting, and also in those of Mr. Parker. Than these few hardy flowers are more desirable, as the blossoms form large, compact rosettes often over 6 in. across, and have a wide variation in colour from the purest white to the deepest crimson; the delicious perfume emitted by them, too, is another recommendation; in many kinds it resembles that of Tea-scented varieties of Roses. These showy flowering border plants are certainly deserving of more extended culture than they get, especially the newer kinds, amongst which are some possessing great beauty.

Tulipa Schrenki.—This is a close ally of the old well-known *Tulipa Gesneriana* of Linnaeus, from which so many of our garden forms have originated. It differs from *Gesneriana* mainly in the form of the flower, which is more funnel-shaped, with more spreading segments. In colour, like *Gesneriana*, it goes through a wide range of variation. Our wild specimens, gathered by Schrenk, have flowers of a uniform pale yellow. The plant from which the drawing was made, which was sent to us by Dr. Regel, they were considerably larger and bright crimson with a yellow throat. It flowers with us at the beginning of April. It has been gathered in Turkestan by

Lehmann and others, and in the Soongarian desert by Schrenk. Since the publication of my monograph of the genus in 1874, the Russian explorers, principally Dr. Albert Regel, have found eight new Tulips in Central Asia—Kaufmanniana, Kolpakowskiana, triphylla, tetraphylla, Kesselringi, Korolkowi, Alberti, and turkestanica.—*Botanical Magazine*.

SOCIETIES AND EXHIBITIONS.

ALEXANDRA PALACE ROSE SHOW.

JULY 5.

THE annual display of Roses held here on Saturday last was in every respect superior to that which took place the previous week at the Crystal Palace, and, considering the unfavourable weather which we have experienced during the few intervening days, the change in the blooms was remarkable. The classes were on the whole well filled, and though we learn that many intending exhibitors withdrew, the show was altogether a fairly representative one, both as regards nurserymen and amateurs.

The class for seventy-two distinct varieties from nurserymen was represented by five exhibitors. The best collection came from Messrs. Keynes & Co., Salisbury, and comprised fine blooms of Dupuy Jamain, John Hopper, Senateur Vaisse, Beauty of Waltham, John Stuart Mill, Captain Christy, Mlle. Eugène Verdier, Dr. Andry, La France, Maurice Bernardin, La Rosière, Cheshunt Hybrid, and others of sterling merit; the other contained several excellent examples of the leading varieties. For forty-eight varieties, three trusses of each, Messrs. Keynes & Co. were again first; the best of these were Etienne Levet, Boule de Neige, Marguerite Brassac, Marie Baumann, Alfred Colomb, Victor Verdier, and Ferdinand de Lesseps. The next in order of merit were Messrs. Paul & Son, Cheshunt, who had excellent blooms of Abel Grand, Prince Camille de Rohan, Dr. Andry, La Rosière, Henry Ledechaux, and others, including their new Hybrid Perpetual Duke of Teck. There were four other competitors in this class. Mr. B. Cant, Colchester, showed the best collection in the class for twenty-four Hybrid Perpetuals only; these were an excellent lot, and amongst the most conspicuous were Duke of Edinburgh, Madame La-harme, Hippolyte Jamain, Exposition de Brie, Prince Camille de Rohan, John Hopper, Mlle. Thérèse Levet, and the old Général Jacqueminot. There were seven other collections shown in this class. The class for twenty-four single blooms was numerously represented, there being ten exhibitors, and the highest award was also gained by Mr. B. Cant, who showed a meritorious collection, the next best stand was shown by Mr. Corp, Oxford. Mr. G. Prince, Oxford, sent the finest dozen of Noisette and Tea Roses, amongst which the best blooms were Marie Van Houtte, Albarosea, Madame Kuster, Souvenir d'un Ami, Rubens, Comtesse de Nadaillac, and Catherine Mermet. The amateurs' classes were on the whole decidedly in advance of the nurserymen's, especially the admirable forty-eight blooms shown by Mr. R. N. G. Baker, Devon, consisting of splendid examples of Victor Verdier, Etienne Levet, Duke of Connaught, Marie Baumann, Charles Lefebvre, Dr. Andry, Duke of Wellington, La France, Captain Christy, Marquise de Castellane, John Hopper, and others. Mr. T. Jowitt was next in order of merit, and the collection shown by him comprised many fine blooms. For thirty-six single blooms Mr. Baker was also first, and though the flowers were good, they were not equal to those in the preceding class. The same exhibitor also took first honours for twenty-four single blooms, in which class there were four other competitors. The next two classes of twenty-four and twelve blooms respectively, were for exhibitors who had not competed in the previous classes. The best of these came from Mr. W. H. Wakeley, Rainham, Essex, who showed a fairly representative collection in good condition. The Tea-scented and Noisette varieties were shown better by the amateurs than the nurserymen; the first prize was won by Mr. T. Jowitt, who had fine examples of Belle Lyonnaise, Rubens, Madame Bravy, Cheshunt Hybrid, Devonensis, Homère, Niphotos, Cloth of Gold, Moiret, and Marie Van Houtte. There were eight other competitors in this class.

The open classes were rather scantily represented. The best dozen Roses of 1877, 1878, and 1879 were shown by Messrs. Curtis, Sandford, & Co., who had Egeria, Madame Albani, Mons. G. Fournier, Princesse Charlotte de Tremouille, Madame Louis Pernet, Penelope Mayo, Catherine Bell, Madame Gabriel Luizet, Madame Sophie Fripot, Marquise Adèle de Murinai, Souvenir d'Auguste Rivière, and Madame Marie Verdier. Messrs. Keynes & Co. were the other exhibitors; they sent Mlle. Marie Castel, Souvenir de Louis Van Houtte, John Fraser, Souvenir d'Auguste Rivière, Innocent Pirola, François Joseph Pfister, Princesse Charlotte de Tremouille, Dr. Kreel, La Saumonné, Ingénieur Modèle, Parthélemy Joubert. For

six blooms of any Rose of 1877, 1878, or 1879, Messrs. Paul & Son, Cheshunt, were first with fine flowers of Emily Laxton; Messrs. Curtis, Sandford, & Co., the other exhibitors, showed Mabel Morrison. For eighteen blooms of English-raised Roses in commerce, fine examples of John Hopper, Cheshunt Hybrid, Peach Blossom, Black Prince, Mrs. Baker, Magna Charta, Mrs. Laxton, Duke of Edinburgh, Oxonian, Annie Laxton, Princess Beatrice, Reynolds Hole, Marchioness of Exeter, Emily Laxton, Miss Hlassard, Prince Arthur, Charles Darwin, and the Sultan of Zanzibar were shown from the Cheshunt Nurseries. Messrs. Curtis, Sandford, & Co., were the only exhibitors of blooms of Baroness Rothschild, and Mr. J. Davis, of Marechal Niel. The delicate-tinted La France was shown finely by Messrs. Curtis & Co., and also by Messrs. Keynes, and the finest blooms of Marie Baumann were sent by Mr. Curtis, Cambridge.

Miscellaneous Class.—The exhibits in this class were by no means numerous, the principal being an interesting collection from Mr. B. S. Williams, Holloway, consisting of Palms, Crotons, Ferns, &c.; also fine plants of Nepenthes, and a group of insectivorous plants attracted considerable attention, as well as the remarkable Caricature Plant (*Graptophyllum Nortoni*), with its prettily variegated leaves and fanciful delineations of faces in profile. Mr. Boller showed his usual collection of Cacti, Agaves, &c., both in large and miniature specimens. From Mr. Ware, Tottenham, came some excellent cut blooms of named varieties of Pyrethrum, of which Mons. Barrall, a deep magenta-coloured kind, was particularly noteworthy. Cut blooms of Pæony were also contributed by the same exhibitor, also a set of Pansies and seedling Picotees and Pinks. Captain Hoiford Thompson, of Exeter, contributed cut blooms of Pansies in numerous and rich variety, which were, with the other additional exhibits, highly commended.

Lists of awards at this and the following shows will be found in our advertising columns.

ROYAL HORTICULTURAL SOCIETY'S ROSE SHOW.

JULY 8.

THE amalgamation of the Pelargonium Society's exhibition with this Rose show and the ordinary fortnightly meeting, together with the exhibits for special prizes, made altogether an extensive and attractive exhibition. The spacious tent, and the narrow one too, were called into requisition, though so much room was scarcely needed, and the large amount of unoccupied space had to be filled with plants from Chiswick. The special display of cut Roses from the Waltham Cross Nurseries, though good, showed unmistakably the effects of the unfavourable weather which we have lately experienced.

First-class Certificates were awarded to the following:—

Begonia Constance Veitch (Veitch).—A fine hybrid of compact habit, bearing a profusion of large deep crimson blossoms, about 9 in. high.

Rhododendron Duchess of Teck (Veitch).—A beautiful greenhouse variety belonging to the Javanese group, with compact trusses of sulphur-yellow blossoms, suffused with a bluish tint.

Begonia Reine Blanche (Laing).—This is without doubt the finest white-flowered variety yet exhibited, and one which well deserves the distinction accorded to it. It is dwarf in habit, has good foliage, and its free-flowering blossoms are of the purest white.

Begonia Edward Morren (Cannell).—One of the finest of the double-flowered kinds, with large rosette-like flowers of good form and of a pleasing deep cerise tint.

Coleus Maude (King).—A variety with elegantly mottled foliage and apparently a free grower.

Pelargonium Mrs. Henry Cox (Hayes).

Pelargonium Volonte National (Perkins).—A useful free-flowering variety, the flowers of which have crisped margins.

Roses.—The Roses shown in the competitive classes were somewhat numerous and better in quality than we anticipated, though not so fine as they would have been had the weather been more favourable. In the nurserymen's classes the blooms from Messrs. Curtis, Sandford, & Co., Torquay, ranked highest in the majority of cases. In their stand of forty-eight varieties, the most noticeable were La France, Xavier Olibo, Madame C. Wood, Abel Carrière, Baroness Rothschild, Magna Charta, Marquise de Castellane, Lælia, Duke of Edinburgh, and François Michelin. Messrs. Paul & Sons, Cheshunt, showed a fine collection for the second prize, the best of which were Glory of Cheshunt, Duke of Teck, Elie Morel, Victor Verdier, Duc de Rohan, Maurice Bernardin, and John Hopper. The best twenty-four varieties, three trusses of each, came also

from Messrs. Curtis, Sandford, & Co., and contained fine blooms of François Michelin, Exposition de Brie, Madame Victor Verdier, General Jacqueminot, and Xavier Olibo. The next best group came from the Cheshunt Nurseries, amongst which the beautiful Duke of Teck, Etienne Levet, Dupuy Jamain, Marie Baumann, and Sultan of Zanzibar were most conspicuous. The best twenty-four single blooms were furnished by Messrs. Laing & Co., Forest Hill, who had Countess of Oxford, Princess Beatrice, Etienne Levet, and François Michelin amongst others in fine condition. In the class for twelve Messrs. Curtis & Co. were again first, thus showing plainly what an advantage the growers in the sunny south have over their more northern friends; and this was further exemplified by the excellent exhibits of the well-known Rosarian, Mr. R. J. Baker, Exeter, who maintained a prominent position in the amateurs' classes. The twenty-four single blooms shown by this exhibitor were superb and very evenly matched. They comprised Marie Baumann, Marquise de Castellane, Marguerite de St. Amand, Sultan of Zanzibar, Ferdinand de Lesseps, Baroness Rothschild, La France, Marguerite Bras-sac, Dr. Andry, Mrs. Baker, Beauty of Waltham, and Prince Camille de Rohan. The finest dozen varieties of three blooms each were also shown by this exhibitor, and were all in excellent condition. Mr. G. Hawtreay showed the best dozen single blooms, and had fine flowers of Duke of Edinburgh, Niphetos, Exposition de Brie, Catherine Mernet, Duc de Chartres, Marquise de Mortemart, Mons. E. Y. Teas, Marquise de Castellane, and Marguerite de St. Amand. The same exhibitor showed the best dozen of Tea and Noisette varieties, amongst which Niphetos, Catherine Mernet, Marie Ducher, Madame Willermoz, Marie Van Houtte, Rubens, Souvenir d'Elise were particularly fine. The next best dozen contained good blooms of Madame Caroline Kuster, Cheshunt Hybrid, Rubens, and Madame Bravy. There were twelve stands shown in the class for six blooms of any Hybrid Perpetual. The highest award was taken by Mr. Baker with admirable examples of Marie Baumann. Mr. B. Cant was next with Duke of Edinburgh. Sultan of Zanzibar and La France were also shown in this class. The corresponding class for Tea or Noisette varieties was represented by six entries; the best came from Mr. Hawtreay, who had excellent blooms of Niphetos. The six best new Roses of 1877 and 1878 came from Messrs. Curtis, Sandford, & Co., who had Egeria, Barthelemy Joubert, Penelope Mayo, Princess Charlotte de Tremouille, Madame Gabriel Luizet. Messrs. Paul & Sons, Cheshunt, showed Robert Marnock, Princess Charlotte de Tremouille, Souvenir d'Adolphe Thiers, Mrs. Laxton, Souvenir d'Auguste Rivière. Messrs. Keynes & Co., who were third, had John Fraser, Oxonian, Madame Gabriel Luizet, Souvenir d'Auguste Rivière, and Boieldieu. For the prizes offered by Messrs. John Laing & Co. for tuberous-rooted Begonias, there were but two competitors, and neither collection contained plants of remarkable merit. The best plants in the first prize group were Acme and Professor Burvenich, two free-flowering varieties of fine drooping habit.

Miscellaneous Plants.—The principal group under this head came from Mr. B. S. Williams, who had an interesting collection of fine-foliaged plants and flowering plants of Orchids, amongst which were Vanda Batemanni, Cattleya Loddigesii, and Dendrobium superbiens. It also contained an excellent group of the so-called insectivorous plants in fine condition. Mr. Wills arranged a collection opposite the preceding, consisting of the fine hybrid *Dracæna* for which his nursery is so famous, intermingled with Palms, Crotons, Ferns, &c., and Gloxinias, amongst which one called Mrs. Causton was particularly noticeable, as the flowers were unusually large and of fine form and colour. Well-grown specimens of the curious and rare *Darlingtonia californica* also formed an important feature in this group. Messrs. John Laing & Co. sent an excellent group, in which some fine examples of Begonias were much admired, as they show to such advantage when arranged with Palms, Ferns, and other fine-foliaged plants. A collection for the most part consisting of New Holland plants was shown by Messrs. Cutbush & Sons, and a corresponding group by Messrs. Osborn & Sons, Fulham. From Messrs. Hooper & Co. came an interesting group of succulent plants intermingled with fine-foliaged plants, and a similar collection was shown by Mr. H. Boller. In addition to the plants certificated as meritorious above, Messrs. Veitch & Sons sent a new Cattleya under the name of *Philbrickiana*, which is a hybrid between *C. Aelandiae* and *C. elegans*, and is quite intermediate in character and superior to either of the parents; *Lilium Anglesii*, a cross between *L. croceum* and *L. tigrinum*; *Begonia rosea* *superba*, *Admiration*, and *International*. *Sarracenia formosa*, to which we allude elsewhere, was also shown; also two fine varieties of *Gloxinia* named *Jeanne Mernet* and *Sylphe*.

Messrs. F. & A. Smith, Dulwich, set a showy group in which Pelargoniums were the main feature, some of which were particularly fine. The beautiful feathery *Asparagus* (A. plumosus) was also shown in fine condition, and well exemplified its adaptability as a decorative plant. Hardy flowers were shown better than they have

hitherto been this year. These came from Mr. Parker, Tooting, and Messrs. Barr & Sugden. The former exhibitor had a fine collection of cut blooms of Pæonies, Delphiniums, Pyrethrums, double-flowering Potentillas, good examples of Hydrangea Thomas Hogg, Cypripedium spectabile, Spiræas, and cut flowers of Erigeron macranthum and the pretty Coronilla iberica. Messrs. Barr & Sugden's collection was extensive, and consisted of cut blooms of English and Spanish Irises; of the former a pure white form was particularly noteworthy, also a rich deep purple one named Plutargus, both amongst the finest we have yet seen. The pretty *I. lusitanica* and its variety *sordida* were also shown. A numerous collection of Sedums and Sempervivums were also a prominent feature, and amongst the latter the handsome *S. Regina Amaliæ* was very attractive by its neat and compact appearance. Cut blooms of Lilies were also shown in this collection, and also by Mr. McIntosh, Duneevan, Weybridge, which comprised *L. Humboldti*, *Robinsoni*, *testaceum*, *Martagon* with its varieties *album* and *dalmaticum*, *longiflorum philadelphicum*, *pardalinum*, and several forms of elegans. Mr. H. Hooper, Bath, exhibited a fine collection of cut blooms of Pansy, Ranunculus, Pyrethrum, Pink, and Pæony, which were highly attractive. Bouquets and furnished vases were shown by Messrs. Smith & Larke, Kensington, and a rustic aquarium and hanging baskets by Mr. J. Langbein, Wandsworth Road. A small group of wax flowers was contributed by Miss Mary Bishop which were faithful imitations of the objects they were intended to represent.

EVENING FÊTE.

JULY 9.

This was a brilliant entertainment, owing to the electric lighting, which was most satisfactory, especially that in the conservatory and upper part of the garden. A collection of scientific instruments and other objects of interest was exhibited by Messrs. Veitch & Sons, in the upper arcades, where there was also a collection of Cones from California and other vegetable products, &c., from various countries. The greater portion of the exhibits shown on the previous day were in the great tent, and were supplemented by several bouquets and other floral devices from Mr. J. Bromwich, Buckingham Palace Road. The brightness of the electric light had a beautiful effect on the varied hues of the plants and flowers, and it was interesting to observe how some of the colours showed themselves better than others under the artificial light. Many officinal and medicinal plants were shown on this occasion by Mr. Bull, Chelsea, who also had a collection of the so-called carnivorous plants (including several new kinds), *Nepenthes*, *Sundews*, *Venus' Fly-traps*, &c. Mr. Bull likewise exhibited a collection of plants with handsomely-marked leaves, such as *Anætochili*, *Microstylis*, *Sonerilas*, *Goodyeras*, *Bertolonias* of various kinds, including *B. superbiissima*, popularly known as the Jewel Plant.

PELARGONIUM SOCIETY.

JULY 8.

The exhibition in connection with this Society was an extensive one, and occupied the greater part of a long tent. The exhibits on the whole were excellent, though some of the classes were but scantily represented.

First-class certificates were awarded to: Mr. Foster, Clewer Manor, Windsor, for show Pelargoniums *Alice*, *Invincible*, *Fug Captain*, *The Baron*, and *Sensation*; Mr. Chas. Turner, Slough for *Fireball*, *Sarah Bernhardt*, and *Electric Light*; Rev. A. Matthews, for *Joe*; Messrs. F. & A. Smith, Dulwich, for *Arab*; Mr. H. Little, for *Miss André (Jackson)* and *Rosy Little*; Mr. Hayes, Edmonton, for *Princess of Wales (Bull)* and *Lady Isabel*, both of the decorative class. Dr. Denny was awarded a certificate for *Black Prince*, a good show variety; *Dauntless* and *Pioneer*, fine double-flowered kinds; *Commander-in-Chief*, *Horatius*, *Dudu*, *Allegro*, *Romeo*, and *Leander*, single-flowered kinds of the zonal type. A certificate was also awarded to Mr. Catlin for *Fanny Thorpe*, *Lizie Smith*, and *Edgar Catlin*, also single-flowered varieties.

In the competitive classes Mr. James, Islevorth, showed the best half-dozen show kinds, consisting of *huc* plants of *Snowflake*, *Archduchess*, *Mary Hoyle*, *Princess of Denmark*, *Pompey*, and *Prince Leopold*—all superbly flowered. For six show varieties not in commerce, Mr. Charles Turner showed *Nero*, *Osman Pacha*, *Joe*, *Bertha*, *Constance*, and *Amethyst*. Mr. E. B. Foster was next in order of merit with smaller plants of *Renown*, *Fireball*, *Prince Imperial*, *Mountain of Light*, *Hectæ*, and *Vahant*. Mr. James also was first in the class for six of the fancy type, and was far in advance of the other groups shown; the varieties were *Morello*, *Princess*

Teck, the *Shah*, *Ellen Beck*, *Mrs. Alfred Wigan*, and *East Lynn*. For six varieties not in commerce of the fancy class, Mr. Turner showed *Polar Star*, *Loadstone*, *Thurio*, *Jeanette*, *Mrs. Milne Home*, and *Sarah Bernhardt*. In the class for eighteen of the decorative type, Messrs. J. & J. Hayes, Edmonton, showed a well grown group of leading varieties. The same exhibitors were first in the next class for six plants of the same type not in commerce; they consisted of *Black Prince*, *Princess of Wales*, *Madame Favart*, *Lady Isabel*, *Harlequin*, and *Maid of Kent*—all excellent examples of good culture. Mr. J. Catlin, Finchley, exhibited the premier group of single-flowering zonal kinds, comprising fine plants of *Lizzie Brooks*, *Titania*, *Lucey Bosworth*, *Rev. A. Atkinson*, *Ellen Pearson*, *Mrs. Leavers*, *Remus*, and *Mr. Catlin*. The same exhibitor also showed the best group of eighteen varieties of the same type. Dr. Denny, who was the only exhibitor for six plants of this class not in commerce, exhibited *Lahoni*, *Lavender*, *Allegro*, *Romeo*, *Dorothea*, and *Ivanhoe*. The same exhibitor also showed the only six of the double-flowered kinds not in commerce; these comprised *Pioneer*, *Gorgeous*, *Stability*, and *Refinement*. Mr. Cannell, Swanley, showed cut blooms of zonal Pelargoniums, both single and double flowering kinds, and took the first prizes in each class. Similar collections were shown also by Messrs. Turner, James, and Taylor.

Special Prizes.—Several excellent collections competed for the prizes offered by Messrs. Carter & Co. for twelve varieties of vegetables. The best came from Mr. Miles, gardener to Lord Carlington, Wycombe Abbey, who had excellent dishes of Stanfordian Tomato, Tender and True and Telegraph Cucumbers, Sutton's Early Snowball Turnip, William I. and Laxton's Unique Peas, Canadian Wonder Beans, Nantes Early Horn Carrots, Seville Long Pod Beans, and Early London Broccoli. The next best collection contained some admirable examples of good culture, amongst which the most noticeable were Carter's White Advancer Bean, William I. and Harbinger Peas, and Carter's Giant Cos Lettuce. In the class for four dishes of Peas, to include Carter's Telephone, Little Wonder, Challenger, and Culverwell's Telegraph, Mr. Richardson, Boston, was the only exhibitor.

The only collection exhibited for Messrs. Hooper & Co.'s prizes for twelve kinds of vegetables came from Mr. Iggulden, Romford, and contained fine examples of Paragon Cucumber, Hooper's Favourite Onion, Nonsuch Turnips, Round White Potato, Incomparable Market Pea, Covent Garden Perfection Potato, and Acme Tomato.

The same exhibitor also showed excellent dishes of Peas in competition for Messrs. Sutton & Sons' prizes, and was awarded the first prize.

Fruit.—Though no prizes were offered on this occasion for fruit large quantities of it were exhibited, especially in the way of Melons, consisting chiefly of seedling varieties, but none were of sufficient merit to obtain certificates. Mr. Perkins, Stanmore, showed a fruit of a Providence Pineapple which weighed 10 lb. Peaches and Nectarines were exhibited by Mr. Goodacre, Elvaston Castle, and Mr. J. Sparer, Ulverstone. A numerous collection of fruit trees in pots, consisting of Peach, Nectarine, and Cherry, were shown by Mr. Rivers, Sawbridgeworth, and a similar group also came from the Society's garden at Chiswick.

REMINISCENCES OF THE ROYAL HORTICULTURAL SOCIETY'S FOUR DAYS' SHOW.

The bank of hybrid Clematises shown on this occasion illustrated in a remarkable manner the value of persistent effort, and the benefits conferred upon the community at large by the specialist. By the use of these Clematises striking effects may be produced in various ways. They make grand pot or box plants for the interior or exterior adornment of the dwelling house, and there is no reason why, when they become better known, they should not mingle their large, gorgeous, salver-shaped flowers with the *Rose*, *Honeysuckle*, and *Jessamine* on every cottage porch where flowers are cared for. I have selected the following dozen from the collection exhibited, viz., *Mrs. G. Jackman*, *Edith Jackman*, *Robert Hanbury*, *Fair Rosamond*, *Sir Garnet Wolseley*, *Stella*, *Countess of Lovelace*, *The Queen*, *Lord Derby*, *Precision*, *Lady Egmont*, and *Lord Lonsborough*. The work that the Messrs. Jackman have done for the Clematis, Messrs. Laing are doing for tuberous-rooted Begonias, as the grand collection that firm exhibited fully testified. Both in the parterre and the greenhouse these kinds of plants have a brilliant future before them, and they are so easily raised from seeds that no one who has the command of a frame and a gentle hotbed in spring need be without them, as good-sized blooming plants may be obtained for months.

The Japanese Maples in Messrs. Veitch's collection deservedly attracted a good deal of attention. Such dainty little trees with elegant feathery growth are sure to be sought after for the greenhouse and conservatory, even if they do not prove quite hardy in all parts

of the country, especially as they are offered at a very cheap rate. The most useful varieties are *Acer polymorphum palmatifidum* (green leaved) and *A. p. dissectum* (a purple-leaved kind). The Roses in pots were a magnificent show of themselves; but some of the monster Azaleas were disappointing from their rigid outline, for they told of skill and time worse than wasted. I hoped to have seen the classes for hardy plants and cut flowers better filled, but even as it was they elicited a good deal of admiration—"Oh! those dear old English flowers" was uttered more than once in my hearing during the few minutes I stood near them.

The collection of Alpines sent up (not for competition) by Messrs. Osborn was a most interesting one, and contained a goodly number of Saxifrages, including that interesting little species *S. muscoides atro-purpurea*. There were also the showy *Cypripedium Calceolus*, *Phloxes*, *Gentians*, *Geums*, *Geraniums*, &c. The small plants of Ferns that were mixed with the Alpines took off the stiffness of this interesting collection and added to the effect. As regards the groups arranged for effect, in the best efforts relieving or toning-down tints of green had been largely employed. This was specially the case with the first prize collection; indeed, Mr. Wills has revolutionised and reformed the system of floral decoration by his lavish and tasteful use of green, and the large variety of surface which his groups afford; but this did not prevent his giving prominence to specially attractive features, such as, for instance, the grand Pitcher Plant, that formed the centre of the group. In direct contrast, at the other end of the large tent, was the green and white group of Mr. Aldous, which was wonderfully chaste and quiet. It was, perhaps, just a little too crowded, and the background of Palms was, I think, too sharply defined, as a little scattering of the front rank of the background would have taken off the flatness of the group. Most of the materials employed were of a common character, and within the means of most people who have glasshouses, and the arrangement, I know, was favourably noticed by many ladies. White flowers are always effective, when associated with young fresh green foliage. How striking at this season are the white Lilacs, rising in dense, cone-shaped masses amidst the bright green of Box and Laurel in the shrubbery. So also are the common Horse Chestnuts against a background of Limes and Elms in the park. How effective, too, are the round clumps of the Bird Cherry in the woods in association with the varying tints of the expanding foliage of the Oak. But no one who has had much to do with the arrangement of plants requires to be told how effective green and white may become in tasteful hands; and the purer the white and the brighter and fresher the green, the better the effect will be. Hence white and green arrangements are never so charming as in early spring, when all Nature is so fresh and beautiful. E. HOBDAY.

first of fence posts, then of railroad ties, then of split timber, and lastly of good saleable timber and logs. This plan, which entails some expense at first, is, however, a very profitable one, and at the same time a very picturesque one. This latter point is of more importance than most people are ready to grant for it.—*Country Gentleman*.

ANSWERS TO CORRESPONDENTS.

Fungi in Flower Beds.—I have lately laid out a small garden, and obtained some earth for it from a heap dug out to make room for the foundations of a house. Lately the beds are covered with fungi, of which the enclosed is a sample. Can you furnish me with the name, and the best way of getting rid of the nuisance?—**FUSLE.** [The name of your fungus is *Peziza vesiculosa*. It is very common in gardens and waste places, and on rotten straw, manure, and rubbish everywhere. It never grows in dry or sweet places, and this may afford a hint as to its extirpation.—S.]

Cucumber Root Insects.—I send you some roots of Cucumber plants; you will perceive that they are destroyed by some insect. I am a large grower under glass for the market. Can you tell me what the insect is, and how I can destroy it? The matter is most serious to me.—**G. S. D.** [On carefully examining the roots of the Cucumber sent, which were much decayed, I found two species of mites, one translucent mite yellowish brown, with long legs, very active, and trying to hide away when disturbed; the other chestnut brown, very shining and sluggish in its movements. Also a small member of the large family of beetles known as *Brachyelytra* or *Staphylinidae*, and a colony of very minute thread-like white worms. All these I think were attracted to the decaying roots, and not the cause of the decay, which I should suppose arose from some defect in the cultivation. We should clear out the plants, renew the soil, and plant afresh.—**W. H. S.]**

Planting Orchards.—I intend planting an orchard of two acres of heavy land, also two of gravel or mixed soil, with apple and pear trees, and shall feel obliged if you will kindly let me know the kind of trees to plant on the different soils; also those that are likely to prove the most lucrative. I shall further be glad if you will mention which kind of soil suits cherries; also the kind of cherry that sells best in the London market.—**G. G.** [If your heavy land is well drained (and it is useless to plant fruit trees of any kind if it is not) you will get the finest fruit and the trees will last longest on the heavy soil. If the light soil be deeply tilled, it will be equally productive for a time, but will require to be manured freely to keep up its fertility. Cherries of all kinds do best in moderately rich, sandy, and calcareous soil; the best market cherries are the Morello, Kentish, May Duke, Black Heart, and Bigarreau. The following varieties of Apples and Pears are hardy, prolific, and certain bearers, and in every way adapted to orchard culture, and will do well on either portion of your land: Apples—Blenheim Pippin, Cox's Pomona, Cellini, Kentish Fill-basket, Devonshire Quarrenden, Golden Nolle, Winter Colman, Yorkshire Greening, Gloria Mundi, Norfolk Bearer, Keswick Codling, Golden Winter Pearmain, Northern Greening, and Reimette de Canada. Pears—Hesle, Jersey Gratioli, Swan's Egg, Eyewood, Autumn Bergamot, Jargonelle, Winter Nelis, Marie Louise, Thompson's, Beurré Rancee, Comte de Lamy, Louise Bonne of Jersey, Beurré de Capiaumont, and Williams' Bon Chrétien.—**W.]**

Erigeron uniflorus and Potentilla Clusiana.—During a tour in Tyrol from which I have just returned, I sent home by post various plants which I was anxious to grow, if possible, in my rock garden. Two of these, which were new to me, I make out to be *Erigeron uniflorus* and *Potentilla Clusiana*, and the plants sent by me are now doing well in a box of peat and sand on a shelf in the Peach house, where there is ample ventilation, and they are protected from the storms and wind which are so trying at this time to delicate plants. The *Erigeron* grew in large tufts on the porphyry cliffs near Botzen, say from six inches to a foot high, and was an extremely handsome showy plant in its native habitat, the individual flowers not unlike *Stenactis speciosa*. The *Potentilla* grew in a rocky mountain pasture, some 2000 ft. above the valley of the Eisack (in which Botzen is situated); in habit and growth it is very like *Alchemilla alpina* were it not for its flowers, which were in loose panicles of the purest white. I should be glad to know if any of your readers have grown these two plants successfully, and if so, whether they require any particular treatment. I am doubting whether to leave them in the box till next spring, or to plant them in peat in a sheltered nook of the rockery, wedging them well in with pieces of broken stone; as I have four or five plants of each, perhaps I might try some in the open air, and give protection to the rest. I found them both in decidedly peaty soil, mixed with rocky grit.—**GEORGE H. CORNEWALL, Moccas Court, Hereford.** [The plants in question are perfectly hardy and succeed well on a thoroughly drained rockery, in a fully exposed position. They thrive and flower in a mixture of loamy soil and grit, but it would be interesting to observe the results when grown in peaty soil as you suggest, as they may grow finer in that than under ordinary treatment.—**W. G.]**

Transplanting and Pruning Hollies.—What is the best time for transplanting Hollies, and also for pruning them?—**L. G. D.** [Hollies, as a rule, may be transplanted and pruned either in spring or early in autumn; but in this stultic wet season we should not hesitate to transplant now, provided the ground was ready and properly prepared for their reception.—**S.]**

Names of Plants.—*H. M. R.*—*Cephalanthera grandiflora*. *F. E.*—*Kalmia latifolia*. *H. L.*—Correct, and as you observe is rare in cultivation. *La Touche.*—*Cochlearia danica*. *H. E. M.*—*Genista anglica*. *H. E.*—Apparently *Iris Hartwegii*. *H. T. E.*—*Hemerocallis fulva* fl.-pl.

Question.

Diseased Cucumbers.—What is the disease that has attacked my Cucumbers? and what can I do to check it? They are in a house, and grow most luxuriantly at first, when all of a sudden they seem to be bitten in places, and from the fruit and stalks a substance of a glutinous character oozes out. We have found on the leaves three or four beautiful small bright green beetles, which are covered with smaller insects. Could these beetles or the insects on them bite the fruit and leaves and poison the plants? Last year we had the same disease in the Cucumber house, and we found three of these beetles. We had the whole house whitewashed, and burnt sulphur in it this year, brought fresh manure and fresh soil from some distance, put in fresh plants, and we were flattering ourselves we had got rid of the evil, when all of a sudden these beetles were found, and the disease immediately re-appeared. I shall feel grateful if any experienced Cucumber grower will tell me what best to do with our plants.—**S. L. V.**

Utility of Woodlands for Shelter.—Riding over different parts of our country lately, I noticed how badly the grain has been winter-killed. Nearly all the fields exposed to the north-west winds, on the crest of the hills and in the low valleys running north and south, are very thin and patchy. On the contrary, the fields sheltered from the cold north and west winds are in fair condition, and especially so are such fields as are protected by woods. This is a proof of the great mistake which cultivators commit in clearing large extents and cutting away the woods without first studying the topography of their land, and the consequences of promiscuous slashing down of timber. Judicious action in this respect would have added great value to many of our farms which are now totally denuded, and thus so exposed to the cold winter winds that the crops are greatly diminished, and the income to be derived from them seriously curtailed. A narrow strip of woods left on the crest of the hills, and on the north and west lines of many farms, would pay a large interest, by the increase of the crops which would result from such shelter. Quick growing species in this case should be selected. Chestnuts, Locusts (*Robinia Pseud-acacia*), Birch, Maple, Whitewood, and Poplar, are good kinds for this purpose. I have for several years allowed all the young trees along the fences to grow. I have trimmed them, and quite a number have grown so rapidly that I have trees which will soon be ready to cut for rails, posts, or wood. They take no room, shelter the field, and give some shade for cattle. A friend of mine has a very picturesque way of planting woods. He plants his trees in the shape of a fan. Suppose a square or oblong piece to be planted; he selects the corner best situated for a full view of the piece of land. From this corner-point he traces a quarter-circle, and starts rows from this circle to the outer lines of the field. Of course these rows spread the farther they go from the starting point; and to fill between them new rows are commenced as soon as the distances between the main rows are wide enough. By planting close he obtains, after three or four years, good hop poles. Cutting these so that a judicious thinning only is practised, he gets an early revenue, which thereafter can be followed by subsequent cuttings

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

ORNAMENTAL PLANTING.

THE principal cause of the failure of single trees and of small groups is the neglect of a proper preparation of the soil, as well as of the trees themselves. Generally the plant intended to make an effective single tree, or to figure in a group in park scenery, is brought direct from a much more sheltered situation than the one in which it is planted. Instead of being subjected to such previous treatment as will produce a gradual hardening of its sap vessels, a thickening of its bark, and the enlargement and density of its head, all of which can be obtained by a gradual opening out, it is too often placed in a position where all these qualities are required, while not one of them has been developed. The result of such treatment is that through sudden exposure permanent injury is inflicted upon the sap vessels. All this might be prevented by a gradual removal of the selected tree into a soil and a situation somewhat similar to that for which it is ultimately designed; or, if the tree be of large dimensions, by such a gradual clearance of surrounding objects as shall secure for it a proper hardness of constitution before its final removal. The trenching round and cutting off of the larger straggling roots, though condemned in some quarters, should by no means be neglected, as the fibrous roots, afterwards formed in abundance where good soil is supplied, enable the tree to start at once with a vigorous growth. But the time allowed for the production of these should be proportioned to the size of the tree and the quality of the soil in which it stands, as the poorer the land the longer the period required.

Where single trees are pitted-in upon wet soils, some provision should be made for carrying off the superfluous water, which otherwise drains to the holes in large quantities, in consequence of the looseness of the soil. The only sure preventive for this is a thorough trenching of the whole of the intermediate spaces in the case of groups or clumps of trees, and the formation of some kind of outlet in that of single trees. Where time will not permit of an entire trenching before planting, the work may be carried out afterwards, and the soil thus loosened will greatly aid the extension of the rootlets.

The common tree-guard, such as we frequently see placed around single trees, is much too small for the purpose, and, as it generally forms the best rubbing place for cattle, the soil around the outside of it is often the hardest and worst trodden in the whole park. Where guards are necessary, they should be of sufficient extent to allow of the soil being well dug around and beyond the roots for the first few years after planting. The advantages of planting and fencing-in clumps are not confined to those afforded by the opportunities of intermediate cultivation; there is also the incalculable benefit of mutual protection.

While the characteristic of the mass is simplicity, that aimed at in the group should be variety. Groups require to be differently arranged according as they are to be viewed from one direction only—as when they stand near the margin of a wood and can be seen only from open quarters—or when they occupy more exposed situations and become accessible on all sides. In the latter case, if they stand on level ground and consist of one kind of tree only, considerable variety may be produced by thinning the outsides of the clump and allowing the middle to grow more thickly, by which means the trees in the latter will be drawn up to a greater height. Where the group consists of various kinds, the same effect may be produced by placing the fastest-growing sorts in the centre. Better and more speedy effects may often be produced by close planting and early thinning out; for clumps of trees irregularly planted often suffer so much upon their margins that the outside trees become stunted or permanently deformed. Where glades or recesses are intended to be formed, the more lucid trees should stand in the front or line the openings, and the darker masses occupy the more distant parts. But amongst deciduous trees no incongruity, such as that produced by the unfeathered shafts and unscial tops of Firs, or the thin and meagre expanse of straggling Poplars, should be allowed.

One feature of the English landscape which is deserving of a passing notice is the absence of trees of large size, with the exception of the venerable Yew, from most of our churchyards. The slowness of the growth of this tree, especially in the open spaces generally devoted to the burial of the dead, is probably the principal reason why so few are now to be seen springing up to take the places of those falling into decay. In ancient times the Cypress adorned, or

rather lent its gloom to, the burying ground. For the higher grounds of our country churchyards, many of which are so picturesquely situated, the Cedar seems to be well adapted. In rapidity of growth it far exceeds the Yew, and probably it yields very little to it in point of longevity.

Pluckley, Kent.

A. J. BURROWS.

RHODODENDRONS AT KNAP HILL.

THERE is nothing in the shape of flowering shrubs that approaches the present race of Rhododendrons for their distinct beauty and great variety; and as they have now for many years been seen in and about London, as well as other places, with their flowers opened under canvas, they are wonderfully effective. So treated the light varieties are extremely pure in colour, even more so than when out in the open air; but the deeper coloured kinds suffer to some extent, their true shades being wanting. With a view to seeing them as they are when fully exposed, I lately looked in at the Knap Hill Nurseries during the time when the plants were at their best, and jotted down a few of what I considered the very best and most distinct and beautiful, alike unexceptionable in both their flowers and foliage, for it is well to observe that, however fine the flowers are, if the plants at the time of blooming are deficient of leaves through their inability to stand the winter weather, or to any extent susceptible of injury thereby, it militates greatly against them. Amongst these Rhododendron hybrids there is no description of leaf that I have seen equal to that of the old Catawbiense, a species which appears to impart to all its descendants a like habit of plant as well as character of leaves.

The following sorts were in excellent condition: Lady Armstrong, an old but beautiful kind, rose, heavily spotted; Scipio, rose, with deep spot, fine both as a standard and bush; J. Marshall Brooks, scarlet, spotted with deep bronze; Michael Waterer, crimson spotted; Mrs. Shuttleworth, scarlet, almost white in the centre, beautifully spotted; Sigmund Rucker, magenta crimson, with a deep solid blotch almost black (this is a magnificent variety in every way); Mrs. Henry Ingersoll, clear shining pink, pale yellow centre, heavily spotted; Mrs. John Clutton, white (for purity of colour and general quality one of the very best); Fastuosum fl. pl., semi-double, very large truss, colour mauve, very beautiful in itself, contrasts well with any other shade; Old Port, deep rich plain colour, very effective; Braynum, rose-scarlet with light centre (old, but still at the head of its colour); Snowflake, pure white, fine and distinct; Caractacus, crimson purple, large and fine; delicatum, bluish spotted with brown; Frederick Waterer, crimson; Othello, crimson purple; Nero, rosy purple, deeply spotted; Lady Frances Crossley, pinkish salmon; Mrs. Mendel, pink shaded with white, yellow centre; lucidum, deep lilac spotted with brown; James Nasmyth, lilac blotched with maroon; H. W. Sargent, crimson; Helen Waterer, white centre with a crimson edge; roseum elegans, colour rose, old, but in its way not yet surpassed. Of unnamed seedlings I remarked one in particular, pale violet in colour with yellow blotch. Another, pure white, with deep crimson spots, tinged with pink: if I were asked to confine my selection to two varieties, one light and one dark, I should take this to represent the former colour, and Sigmund Rucker for a dark. Amongst the large number of fine Rhododendrons now in cultivation, the above may be relied upon as not likely to be surpassed.

P. G.

The Flowering Ash.—There has lately been overhanging the village green at Belfont a fine specimen of the *Fraxinus Ornus*, or Flowering Ash, in beautiful bloom. The heads of bloom, borne at the extremity of every small twig, almost resembled in form and inflorescence as well as colour the feathery spikes of the *Hoteia japonica*, though perhaps more drooping, like the elegant heads of the Pampas Grass. This is one of those trees so rare in gardens that one may visit hundreds and not find it. As a flowering tree it is one of the most beautiful, and yields the palm to none in the graceful elegance of its bloom. I have met with but one previously, and that, a smaller tree, growing in the pleasure grounds of the Wilderness, near Reading, a part of the once famous White Knights' estate. A peculiarity of that tree was the excessive size of the base of the stem of the common Ash on which it was grafted, and which was more than twice the diameter of the scion. In planting in more recent days, the desire for varieties of the *Pinus* family, with their erect and formal outlines, has largely contributed to keep many of our most beautiful flowering deciduous trees in the background. Perchance the marvellous wealth of bloom found on all such this year may again tend to revive that liking for flowering ornamental trees that existed in the days when these choice Ash and other beautiful trees were planted. Crabs, Peaches, Pyrus, Laburnums, Horse Chestnuts, Almonds, double Cherries, Tulip trees, Paulownias,

Fraxinus Ornus, pink and scarlet Thorns, white Mespilus—these and many others tell what a wealth of bloom and beauty is to be found by the planter among our deciduous trees.—A. D.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Paulownia imperialis at the Knap Hill Nurseries.—From time to time we hear of this tree producing flowers in some part or other of the country, but the blossoms are generally few and far between. Such, I understand, has hitherto been the case with the Paulownia at the above place. It was planted some twenty-five years ago, and has now reached a height of about 30 ft., the spread of the branches being about as much. When I saw it recently it was well clothed with deep purple-shaded lilac flowers in shape not unlike those of a Lentenon, but much larger. This tree is very late in leafing, and blooms in a quite leafless state; the flowers are produced from the last season's wood, in this case clothing some 9 in. or 12 in. of the extremities. It has a distinct and singular appearance; the colour, so uncommon in arborescent subjects, is seen to the best advantage at some little distance off when the sun is shining upon it.—T. BAINES.

The Eucalyptus in the Isle of Wight.—The Eucalyptus tree has escaped in some places in the Undercliff from the effects of the late severe and protracted winter, the worst I have known in this island during my sixty years' experience of it. This tree has less to fear from our frosts than from our winds charged with sea-spray. It requires to be planted in the centre of a screening belt. It is not likely to add much to the beauty of foliage, except by way of contrast.—LAURENCE PEEL, in the *Times*.

Paulownia imperialis.—The Right Hon. H. P. Vercker, of the Pitts, Isle of Wight, in a letter to the *Times*, reports that "in the pleasure grounds at Binstead there is a fine specimen of this tree, which, planted in 1852, has flowered abundantly for the last ten years. It overtops the forest trees around. When viewed from above, the effect of its carpet of light violet-blue flowers is extraordinarily beautiful in contrast with the dark foliage around, reminding one of those bright-flowering trees which are rarely to be seen outside the tropics."

Eucalyptus globulus at Killarney.—Two of the loftiest and most perfect specimens of this Eucalyptus that we know of are those at Dinas Island, Killarney. We are gratified to learn from Mr. Campbell, forester at Muckross, that it has come quite safely through the late severe winter. Mr. Campbell states that he recently measured the larger one of the two, and found it to be 50 ft. in height, and 2 ft. 6 in. in girth.—*Farmer's Gazette*.

Two Hardy Shrubby Plants of the Central Nevada region, writes Prof. Sargent, in the *American Journal of Science and Art*, may be mentioned which, from their beauty, are especially worthy of introduction to cultivation. (1) *Cowania mexicana*, a large Rosaceous shrub, nearly allied to *Cercocarpus*, with elegant pinnatifidly-lobed leaves, and large and very abundant yellow flowers; and (2) a large shrubby *Spiraea*, *S. Millefolium*, with the foliage of *Chamaebatia*, but a larger and more striking plant, and perhaps the most elegant of the genus.—*Florist*.

Street Trees.—We have read with much interest Mr. Dennis's remarks (p. 506) on street trees, and while fully agreeing with what he has stated respecting planting, &c., we should like to say a word or two about the varieties best adapted for that purpose. In the first place there can be no question about the excellence of the Plane for street planting, but while admitting the usefulness of the black Italian Poplar, we consider *Populus canadensis nova* much better for the purpose under notice, as in rapidity of growth and appearance of foliage it far surpasses the black Italian. Avenues of this tree may be seen at Wimbledon Park, where we planted it along with the Oriental Plane.—J. CHEAL & SONS, *Longfield Nurseries, Crawley, Sussex*.

The *Daphne japonica variegata* is an evergreen sweet-scented flowering shrub, which, though old, ought to be more extensively grown. It is hardy, or very nearly so, since we learn that a bush of it some 3 ft. high and nearly as much across, stood out for many winters, until removed to make way for alterations, at the Great Berkhamstead Nurseries, where it used to scent the whole quarter on which it stood. It is a remarkably free bloomer, hundreds of young plants there in the cold pits being in full blossom, and not more than 2 in. or 3 in. in height. It has, as is known, something of the aspect of *D. indica* or *D. odorata*, but appears to be hardier than these. The flowers are tinted with a flush of pale purple, and deliciously scented, and though perhaps scarcely to be called showy, are very pleasing in appearance.—*Florist*.

Spiraea trilobata.—One of our common *Spiraeas* has pleased me greatly this season, viz., *S. trilobata*. Though long familiar with the plant, I had apparently never before so fully realised the charm of the graceful curves of the branches, the delicacy of the leaves, and attractive set of the flower. *Spiraea Reevesiana* is always beautiful late in spring, both in flower and general habit. It has, indeed, gained the lovely name of Bridal-wreath *Spiraea*, but to me either *S. Thunbergi* or *S. trilobata* merits more justly this honourable title. *S. trilobata* bends almost into semicircles, its branches being laden with exquisite rosettes of pure white flowers. Scarcely any cluster of sprays is more beautiful for the decoration of rooms than the curving branches of this *Spiraea*. Old shrubs like these should not be neglected, which I fear is too much the case with *S. trilobata*. It may not be amiss to note here the importance of pruning *Spiraeas* immediately after they have done flowering. Not only is the bloom rendered more abundant by thus pruning, but the foliage also is greatly improved.—*Rural New Yorker*.

Effects of the past Winter on Shrubs, &c.—In a park situated in a valley about 120 ft. above the sea, and on soil originally a heavy clay, the Cork and some *Hlex* trees, the common Bay, the common *Laurustinus*, and *Olea ilicifolia*, are much browned. A tree of *Magnolia grandiflora*, quite unprotected, *Aralia japonica*, *Osmanthus*, *Azara microphylla*, *Elaeagnus variegata*, *Onaria Hasti*, *Raphiolepis ovata*, *Skimmia oblata*, male and female, *Viburnum latifolium*, *Berberis Darwini*, are uninjured. A large *Chamaerops Fortunei* looks as handsome as ever now its curtain of mats has been removed. Both in the park and in my own small, wall-girt, town garden, *Ceanothus azureus* (15 ft. high), *Escallonia macrantha* and *alba*, unwisely pruned in the autumn, *Benthamia fragifera*, *Grislinia macrophylla*, *Buddleia globosa*, *Cistus angustifolius*, *Hypericum patulum*, were nearly killed, but are now sending out new shoots. The small-leaved *Myrtle*, *Veronica Hendersoni*, *Fabiana imbricata*, are killed, while on the same wall a large plant of *Daphne indica rubra* is only browned, and blooming freely. *Eulalia variegata* is renewing its beauty, whereas the Pampas Grass and *Arundo Donax* have scarcely recovered; the latter has suffered least. Some *Tritomas* are killed and *Scilla peruviana*, but all other bulbous plants are uninjured.—J. S. BARTUM, *Bath*.

Hardy Azaleas.—At the Knap Hill Nursery there is now a completely distinct break of hardy Azaleas yet unnamed or brought before the public. They are the result of many years' work in crossing, often repeated until the flowers of some of the best would, at first sight, scarcely be recognised as belonging to the hardy section of Azaleas. I saw them in bloom a short time ago and took notes of several; the petals are 1 in. broad, some pointed and recurved as in the well-known Ghent varieties, others blunt and rounded, so much so as to closely resemble the ordinary Chinese and Indian greenhouse hybrids, long so generally cultivated. In colour they run through all the shades of red and crimson, yellow and bronze, pink and flesh, to white. In addition to the immense improvement in the character of the flowers another object has been kept in view, that is, to keep on raising from such as showed a disposition to produce plenty of leaves before the bloom opens; not being furnished with leaves is a defect in the Ghent varieties. This has been secured along with a late habit of flowering; they are quite a week behind the Ghent kinds, which places them out of the danger of spring frosts. They will form a most important feature amongst hardy spring-blooming shrubs.—P. G.

The assegaïs used by the Zulus are described in Poter's "Dictionary of Military Science." The name of "assegai," or "hassagaie," is derived from the tree from which the wood is generally taken which is used for making those weapons. The tree, the botanical name of which is *Curtisia faginea*, is called "hassagaie" by the Zulus.

Dewponds.—These are, to the inexperienced and the unobservant, myths; but they are facts of considerable importance to farmers, and bear direct relation to the water supply of villages. Of their interest for the archaeologist we have agreeable illustration in the paper contributed by Sir George Duckett to the April part of the "Wiltshire Archaeological and Natural History Magazine." It is entitled "Observations on the Water Supply of some of our Ancient British Encampments," and is an endeavour to solve the curious problem of how water was obtained within ramparts situated upon high levels or hills. The author decides that rain water was collected in deep pits or excavations formed within the area of such entrenchments, the reservoirs being rendered watertight by "puddling." The pits when once full would be kept supplied not only by rains, but by the aqueous vapours and mists which hang about the tops of high grounds. The editor of the magazine in question adds a note to confirm Sir G. Duckett's theory, and remarks that of late the Wiltshire farmers, having learned the value of "cloud ponds" or "dew ponds," have formed them at much expense on the tops of the hills.

PROPAGATING.

THE AUTOMATIC BUDDER.

THE budding season is late this year, but it promises to be successful, inasmuch as, with so much sap alike in scion and stock, the buds are likely to come out and also go in clean and well. But it is this getting of the buds out and placing them in quickly and neatly that is at once the secret of successful budding and the plague of amateurs and not a few professionals. Hence, were it possible to have some better or more effective mechanical help to budding than a common knife, such invention could not fail to become as popular as it would be useful. Messrs. Ward & Garrard, of Ipswich—the one so universally known as one of the most successful cultivators and raisers of Roses, and the other as a clever inventor—have, after many attempts, brought out a budder that does its work in a rapid, easy, and perfect manner. I have examined and tested it in various ways, and think it only fair that the inventors should be permitted to introduce this useful implement to your readers in their own words, which by no means exhaust, far less exaggerate, its merits:—

“The object of this invention is to facilitate the art of budding. Notwithstanding all the instructions that have been given, budding is still a somewhat difficult and delicate operation. However handy the budding knife is at present in the hands of practical experts, it is at best ill adapted for the purpose, and difficult to handle, especially by amateurs. The operation of budding often proves a failure by the bark being improperly raised, and by the danger to the bud by insertion. All these risks and difficulties are avoided by the use of the new Patent Budder. The transverse cut, so injurious to successful budding, is by its use dispensed with. The operation is of a very simple description—the bud being cut in the ordinary way

Fig. 1.

Fig. 2.

is at once placed on the needle point as shown in fig. 1, being then ready for the next operation of insertion; press the cutting edge of the Patent Budder on the bark, moving it gently along a sufficient distance to receive the bud. The bark will then be cleanly cut and opened, the cambium uninjured. By touching a small spring with the finger, the bud is pushed from the base of the budder, and left in the best position for speedy and healthy growth. It has been carefully tested during the last budding season, and after many expensive and exhaustive experiments, the art of budding is successfully placed within the reach of all, and in the hands of professional budders the result is being able to accomplish this operation six times quicker than by the ordinary method. It is confidently anticipated that a complete revolution will be effected in the budding of Roses and fruit trees by thus simplifying the process, and bringing the fascinating and delightful art of budding within easy reach of all.”

D. T. FISII.

PROPAGATION OF PINKS.

WHILE Carnations and Picotees are increased by layers made at the end of July and in August, Pinks are propagated by means of cuttings or pipings, and this is done in June or early in July—later this year than usual because of the general backwardness of the season. Where Pink piping is largely done in consequence of a great stock being wanted, it is the usual practice to make up a bed of manure and leaves so as to get a gentle bottom heat: on this a layer of suitably light sandy soil is put, and the pipings put in in squares, centres, &c., according to the slope and dimensions of the hand-lights placed over them. The cuttings are put in thickly and kept shaded from the sun, and a very large majority will take root. It is not always convenient to make up a bed, and it is not difficult to strike pipings in other ways. Mr. James Clark, of Bury St. Edmunds, the raiser of some very fine forcing Pinks, makes up a bed between his Gooseberry trees, providing a soil with plenty of sharp sand in it, and inserting his cuttings; he puts hand-glasses over them, thus

raising numbers of plants, and is indeed very successful. Pinks will root as freely under a north wall as anywhere, and they require less attention in the matter of shading in such a position. A good mode of making up a bed under a north wall is to prepare a layer of horse manure that is nearly deprived of its heat, put it together thoroughly wet, and beat it down with a spade to a level surface to a depth of 9 in. or 12 in., which will be quite sufficient to keep worms from disturbing the young plants. On this should be placed 3 in. of compost suitable for rooting the pipings in. This should be used in a moist state, but not wet and clogged with moisture, and it should be made smooth on the surface. A good compost for Pinks is made up of leaf-mould, or any decayed vegetable mould, and silver sand sifted fine, equal parts of each. In the absence of the above materials, a good free sandy loam will answer, but preference should be given to leaf-mould and sand, as it is cool and retentive of moisture.

Pink cuttings or pipings should be made from the young wood of this year's growth, and when these are removed their lower leaves should be stripped off to within two or three joints of the top of the cutting; then, with a keen-edged knife, the lower part of the shoot should be cut away close under the joint selected for the base of the piping. When all to be put in are prepared, it is a usual practice to throw them into water for five or seven minutes to stiffen. The piping bed being ready, the pipings should be put into the soil to the depth of $\frac{3}{4}$ in., and the soil pressed firmly about them. The pipings require to be about 1 in. apart each way. When they are inserted a good sprinkling of water should be given, and as soon as the foliage has dried a hand-glass should be placed over them. In three weeks or so the plants will begin to root, and at this period the hand-glasses may be removed by degrees, first lifting them 1 in. or so on one side for a day or two at a time, then raising them all round, and in a week or so they may be removed altogether.

There is now a large collection of the beautiful laced Pinks in cultivation; if any one is disposed to try his hand at cultivating a few they can be had through any nurseryman. In addition, there are some beautiful border Pinks that are most useful for forcing purposes; of these we may name—Duly Day, deep pink, heavily laced with bright red; Lady Blanche, pure white, does well grown in pots; Lord Lyon, deep rosy-purple, very fine, free, and otherwise good; Mrs. Moore, pure white, with dark centre; Newmarket, a self flower of a reddish-purple hue; and Rubens, with pleasing dark flowers. I have found some of these to provide useful plants in autumn by top-dressing them with a light sandy soil in July; during the summer the side-shoots root into this, and good plants can be had. Lord Lyon is in particular an excellent border variety. R. D.

Heating with Hot Water at Swanley.—At the Swanley Nursery there are a series of low pits, a single light in width, eight in number, each 100 ft. in length, the peculiar arrangement of the pipes for warming which is worth noting. Instead of lying just above the surface of the bottom, or in a cavity round the side in the usual way, the pipes—a single flow along the front, returning on the back—are elevated right up to the under side of the rafters. The flow-pipe in each pit is only 1 in., the return 2 in., which, as the pits are shallow, have been found sufficient to preserve the plants through the winter. These consist of Pelargoniums, Lantanas, Verbenas, Fuchsias, and similar soft-wooded material. Mr. Cannell says that with this arrangement, *i.e.*, the pipes above the heads of the plants, he finds very much less loss of leaf through the winter than when they lie on or near the bottom, where the heat from them naturally causes moisture to rise and to condense on the leaves. So marked has this been during the severe winter through which we have passed, necessitating a long continuance of the use of fire-heat, that the plants have never so much as once needed picking over or other attention in a similar way, and nothing need be healthier than they now are.—P. G.

AMERICAN NOTES.

"Pussley" or Purslane on the Table.—"Pussley," in the older parts of the country at least, is regarded as the representative weed. To be "as mean as pussley," is a common adage. "He lets pussley get ahead of him," is applied to a slack, inefficient cultivator, for in these hot July and August days one must be smart if he keeps his garden free of "pussley." In midsummer days, when Peas have gone, and the flush of sweet Corn, Lima Beans, and other late garden products has not come, "try Pussley"—*Portulaca* if the Latin name sounds better, or *Pourpier* if the French is preferable. We have passed months and months when "pussley," gathered upon the far western plains, was the best green we had. We have tried it since, and can assure those who do not know it as a table vegetable, that it is most acceptable. For ourselves, did it not grow of itself, we should follow the example of the French, and cultivate it; they consume it as a salad and in soups, besides cooking it after the manner of Spinach, or "greens." It should be taken when growing rapidly and its fat stems snap short and tender, and treated like Asparagus. In looking at an article on its culture in a French work on gardening, we find it ends thus: "We know of no injurious insect that attacks the *Pourpier*." Neither do we—we wish we did.

The Massachusetts Horticultural Society offers a special prize of 25 dollars, for the best essay on each of the following subjects: Culture of Flowers and Foliage for Winter Decoration and the Market, with a list of the most desirable varieties; Profits of Farming and Gardening in New England; The most promising new Hardy Ornamental Trees and Shrubs, and their tasteful and effective Arrangement; Upon any Special Action of Fertilisers, illustrated by Accurate Experiments; Upon Flowers for the Home, with lists of the best Annuals, Herbaceous Perennials, and "Bedding Plants." These prizes are designed to elicit new facts, and preference will be given to essays which add the most to our stock of information. Competition open to all. For further information address Robert Manning, Secretary, Boston, Mass.

Silver's Berry Picker.—This is rather a berry-holder than a berry-picker: it consists of a small rubber cup, so held by a loop around the other fingers as to leave the forefinger and thumb free. Its chief use is to avoid the holding of small berries in the hand until enough are gathered to transfer to the basket. For such small fruits as raspberries, huckleberries, &c., it will, no doubt, be found convenient.

London Purple—an Insect Poison.—In April last we announced a new poison for insects, called London Purple. Paris Green is a compound of Arsenic and Copper, and must be prepared direct. London Purple is a compound of Arsenic and Lime, quite as poisonous as the other, but being an incidental product, formed in another manufacture, it is much cheaper. It is artificially coloured of a deep purple, to guard against accidents in its use. It is in a state of very fine division, and it is claimed to be equally efficacious with the Green when used in one-fifth less quantity. Like that it is applied with water or diluted with flour, plaster, or other powder. Recently we have received, from those who have used it for the Potato Bug, testimony as to its complete efficacy. It has also been found to effectively destroy the canker-worm. Mr. Whitney, Nurseryman at Franklin Grove, Ill., writes that the canker-worm took possession of an orchard of 25,000 apple-trees, besides attacking his nursery stock. The use of 12 oz. of London Purple in 44 gallons of water, applied by means of a force pump, destroyed the worms in a short time.

A Late Magnolia.—*Magnolia hypoleuca* has been mentioned and commended more than once for many noteworthy qualities. It is late, blooming in mid-June, creamy-white like *conspicua*, and moreover of a scent so sweet that for the want of a truer comparison, I will liken it to the combined odour of Strawberries and Bananas. I know of no *Magnolia* so delicious, unless it be the tender *M. fuscata*. Now all this is a great deal for a single species to possess in the way of delightful qualities. But Nature seems disposed to give even more, for the foliage of *M. hypoleuca* is simply exquisite. I refer more especially to the young foliage, although the older leaves have fine red stems, and are glossy green on their broad surfaces. But the young leaves, with thinner, more delicate texture, show this red in the veins, and even farther throughout the general green to the extent of a faint tint or tone. The result is a suffusion of most delicate purples lined out with red veins. Held up against strong sunlight the effect is greatly enhanced by the translucent character of the leaf. Portions of the foliage in ordinary lights thus assume a curious bronze colour, as a result of the mingling of shades, and the distinct white of the under side makes the appearance still more remarkable. I dwell particularly on the foliage of this new and rare *Magnolia* that I may enter a plea for the beauty of leaves generally.

Flowers are so valued and set above mere foliage, that the latter, though in many cases quite as exquisite, receives scant justice.—SAMUEL PARSONS, in *Rural New Yorker*.

Weeds.—However well a plant may be established, and the ground is filled with roots and root-stocks, stored with nutriment, each inch of which will make a new plant, every attempt this plant makes to grow will exhaust a part of this underground store. It cannot increase this stock without leaves. If kept from producing foliage, this accumulated store must in time be exhausted. Keep down the leaf-growth and the plant must die. It is only a question which will hold out the longest, man or plant. There are few who will give the needed thorough work; if the plant does not yield to a few hoeings or cuttings, the task is given up. There is perhaps no worse weed in existence than the so-called Horse Nettle (*Solanum carolinense*), which is actually, in parts of Delaware and Maryland, driving people from their holdings. It is said, and generally accepted, that the plant cannot be killed. A friend in Delaware, a good botanist, determined to put his philosophy into practice. He tried the Horse Nettle; as soon as a shoot appeared, off it came; he admits it was a hard struggle, and that to clear it out would cost all that the land was worth—but it can be done.

Dried Persimmons.—Not the "Simmons" of which the Southerners make their "Simmon beer," but the true Japanese Persimmons, several times larger than our native fruit, and as much better as they are bigger, have been sent us by Mr. Chas. H. Shinn, of Niles, California. The Japanese Persimmons are of various sizes and shapes, when fresh, and present a similar variety when dried. In taste they are much like Figs, and if offered in the market would no doubt meet with a ready sale. Mr. Shinn does not state, in sending us the specimens, whether they are from fruit grown in California or are imported from Japan in the dried state.

A Ladies' Garden Club.—A correspondent, well known in horticultural and botanical circles, thus writes: "The ladies of our street have got up a Garden Club! They have got a President—the most experienced plant-grower of the lot—and a Secretary, and a record-book, and they hold meetings once a week, in the afternoon. They won't take in members out of our street—they have got to draw the line somewhere—and they think that a dozen or two women are quite enough for one gathering, whether they all talk at once or take turns. They take two or three horticultural magazines or papers among them, and are going to subscribe for more. At the meetings they read aloud some of the articles, and discuss them, and each one gives an account of her own doings and raisings, how she has managed to get up Sweet Peas, or made Nasturtiums blossom all winter in the parlour, or carried tender plants through the trying season. They are now getting up their orders for flower seeds, and considering what kinds it is best to have. The way I came to know about it is, that I am a bit of a botanist, and know the names of things, and what are annuals or perennials—(per-annuals, as an old neighbour of mine used to call them)—and can tell them what sorts of things a *Calonyction speciosum* and *Zauschneria californica* are, and if they are hardy. So they chose my wife, and even wanted to make her President, though she is not strong in flower growing, and, as to names, gets *Begonia* and *Bignonia* mixed up badly—not for want of knowing the two things, but forgets which is which. So through her and the questions she brings to me, I get a good inside view of the operations. Seriously, this club is useful, and I wish to commend it as an example.—G. A." [This is an example to be heartily commended, and perhaps in a large town small clubs like the one described may be more effective than larger ones. Vineland, N.J., which has been foremost in many good things, has long had a floricultural society composed, if we mistake not, exclusively of ladies, and much of the prosperity of the place may be ascribed to its influence. There are few pursuits in which association is so helpful as in gardening, and clubs of this kind are useful.]

Pigeon-berry or Poke in the Garden.—What is known as "Pigeon-berry" in New England has various other names in different localities; among them are "Poke," "Garket," "Coelum," "Cancer Root," "Skoke," "Skoka," and "Pecatacelleloe"—which last quite puts to shame its botanical name, *Phytolacca decandra*. Whoever has not eaten the tender, just-developing shoots of this, dressed as Asparagus, or as Spinach, has missed one of the choicest of vegetables. It is sometimes compared to Asparagus, but it is not like that—it is a thing by itself, and as good in its way as is Asparagus in its. Knowing from early youth the great excellence of—must we say it—"Pigeon-berry greens," it has long been in the writer's mind to sometime try what cultivation would do for it. In this, as in other cases, "sometime is no time at all," and the only true way is to carry out such intentions at once. As to the "Poke," we have been anticipated. The idea is ours, but some one else has put it in practice, and that some one else is—a lady. We have only imagined how excellent improved Poke must be, but our Illinois cor-

respondent has the advantage of us—she knows it. The lady transplanted young seedlings all along her garden fence; she also had large roots dug up and set out. From these last she says, "We have had the finest, fattest, Poke-berry greens ever eaten." In answer to our suggestion that the tops, when mature, would occupy too much room, she writes, that when the plants get well up she has them cut off at 3 ft. or 4 ft., and that this leaves foliage enough to mature the root.—*American Agriculturist*.

BEARWOOD.

FEW places are richer in landscape beauty than Bearwood, the residence of Mr. John Walter, M.P. It is situated near Reading, on gently rising ground, and is surrounded by fine woodland scenery, the woods mainly Beeches, amongst which there are some of the finest examples with which we have yet met; some of them are of

past an uninterrupted display of flowering shrubs, which are planted in bold groups, with irregular natural-like outlines. The Rhododendrons—except the later flowering kinds—and the brilliant Ghent Azaleas, of which there is a large collection, are for the most part past their best, but the shrubberies are now gay with fine masses of Kalmias, consisting chiefly of *K. latifolia*, with its glossy deep green foliage and dense clusters of wax-like blossoms varying in colour from a delicate blush to a deep rosy crimson. Other kinds of showy-flowered shrubs such as the different species of *Berberis*, *Philadelphus*, *Syringa*, *Escallonia*, *Roses*, and beautiful flowering shrubs belonging to the Pea family, and a host of others, are interspersed with the preceding, or planted in isolated groups. Every kind of shrub appears to thrive here with unusual vigour, especially the Rhododendrons, Azaleas, and Kalmias, though planted in the soil natural to the place, a sandy clay and marly loam, without a particle of peat; nevertheless huge clumps of Rhododendrons, rising from 10 ft. to 15 ft. and even 20 ft. high, afford sufficient evidence, if any were wanted

In the Gardens at Bearwood

great girth, and are furnished with stately heads which have been wind-tossed for centuries, and which are now the only visible remains of the vast tracts of forest which once overspread that part of Berkshire. The mansion, a fine Elizabethan building of recent construction, occupies the highest point in the neighbourhood, and commands some fine views of the gently undulating country lying to the south and east; whilst in the far distance in a northerly direction may be seen the valley of the Thames. From the house an uninterrupted and well-kept lawn gently slopes to the edge of an ornamental lake, consisting of well nigh a hundred acres. This, though formed artificially, has quite a natural appearance—huge branches of Beeches stretching over the surface of the water, in which are here and there dotted some pretty islets. A noteworthy feature at Bearwood is the absence of all elaborate geometric designs, which are too often met with, defacing extensive lawns, and materially detracting from the imposing grandeur of a noble mansion. Here there has been for several weeks

that a peaty soil is not an indispensable condition as regards the growth of what are termed American plants.

A fine collection of deciduous Oaks particularly attracted our attention. Amongst these are not only grand specimens of the indigenous kinds and their varieties, but also of the finest of the South European and North American kinds. Of the latter, we noticed fine examples of *Q. tinctoria*, *coccinea*, *Prinus*, and others, the foliage of which is highly attractive, being much larger than that of the ordinary kinds, and, in most cases, cut into narrow divisions, rendering the trees even now very ornamental in appearance, but much more so later in the year when they have assumed their autumn tints. Another brilliant autumn tree is the Liquidambar (*L. styraciflua*), of which there are here some noble specimens.

Amongst Conifers we remarked some unusually fine examples, both soil and position evidently suiting their requirements admirably, all being in the most robust health. A fine avenue of Sequoia

(*Wellingtonia gigantea*, near the principal entrance to the mansion, is a noteworthy feature, more particularly as the trees were all transplanted a few years ago from various parts of the grounds, some of the specimens at the time being as much as 17 ft. high; now they are in the most vigorous health, without a failure in the whole avenue. This success Mr. Tegg, the gardener here, under whose supervision the operation was carried out, attributes to the stiff and retentive character of the soil, combined, of course, with the skilful use of the most efficient machines and subsequent attention as regards watering, &c. Amongst these Sequoias we noticed a variety with unusually green foliage and distinct in habit, which is not inappropriately distinguished by the name of *viridis*. Amongst the other Conifers that attracted attention were fine specimens of *Picea Pinsapo*, *nobilis*, *Nordmanniana*, *cephalonica*, a grand example of the true *Pinus ponderosa*; also of *Juniperus virginica*, *Abies Smithi*, *Menziesi*, *Douglasi*, and the Hemlock Spruce. The finest tree of *Sequoia gigantea* is one planted about thirty years ago, and which is now a noble specimen. Conifers have been judiciously planted amongst the large deciduous trees and clumps of evergreen shrubs, examples of which are represented in the accompanying illustration. We were somewhat surprised to find here an almost entire immunity from the effects of the past winter in the case of even tender shrubs and trees which in some low-lying districts have been severely injured. Such shrubs as *Escallonia* here that were quite unprotected are unhurt, as are also *Sequoia sempervirens* and others, thus showing the advantage of elevated localities for doubtfully-hardy exotics.

The Rosery, an extensive plot devoted entirely to the queen of flowers, contained all the best varieties, and though the present season has been anything but favourable for a fine display of bloom, there is no scarcity here. An extensive rock garden is in course of construction under the direction of Mr. Pulham, and when finished it will be one of the leading features of Bearwood. Round the lake and adjoining woodlands, we now and then came upon a garden in the natural style, in which the Foxglove and other beautiful indigenous plants blended with the green of the common Bracken which carpets the ground under the huge timber trees.

Though an account of the fruit and kitchen gardens at this fine place is for the present omitted, we cannot bring these remarks to a close without alluding to some grand specimens of white *Lapageria* which we saw in passing through one of the planthouses. A plant at each end of the house is trained to the roof, and each runs the whole length of the house and flowers abundantly. They are grown in pots in a compost consisting for the most part of peat with the addition of fibry loam, road scrapings, and a small quantity of well-decomposed manure. W. G.

THE FRUIT GARDEN.

EFFECTS OF SOIL ON GRAPE CULTURE.

THERE are probably few districts in which the ingredients for a Vine compost that would grow Grapes well could not be found; but I sometimes think that insufficient allowance is made for the effects of soil and other conditions in estimating the qualities of Grapes. I believe that there are soils so specially favourable to the production of Grapes and other fruits, that anybody may succeed with little trouble in producing the best examples in every way, while under other circumstances the highest skill and attention might fail to produce equally good results. I do not wish to make apologies for bad culture in saying this, but simply to state a probable fact, into which it would be well worth our while to look a little further. If there be certain soils better than others for the Grape, it would be very desirable to know their composition. Hitherto, most of the directions given on the subject of fruit-tree borders generally have been of the most haphazard description. Each person uses the soil he can most conveniently procure in his own locality; and under the general name of "loam," turfy or otherwise, he recommends it to others whose "loam" may be of an entirely different description, and produce quite different results. Can it be doubted that soils which differ widely in their composition produce a consequent effect upon the plants that are grown in them? All experience answers in the negative. As regards the Grape, not a few facts confirm this. Years ago, speaking from memory, I remember a dispute in the horticultural papers respecting the Broommouth Muscat Grapes, fine examples of which were exhibited at Edinburgh, and which I believe received a prize. These Grapes were thought not to be Muscats by some, because they were entirely destitute of Muscat flavour, and they were pronounced to be another variety, similar in appearance to the Muscat, but without the flavour. It was proved, however, by growing Vine propagated from the Broommouth ones at another place, and along with the true Muscat of Alexandria, that

they were Muscats. Now, here was a case in which the flavour, the great point of excellence in the Muscat, was influenced by the soil—apparently lost, one might say; and I daresay nobody would use such a soil, or one approaching it in quality, if he knew that it would produce such a result.

These facts—which in this country are exemplified only in a fragmentary way—are, it would appear, confirmed on a far more extensive scale in the Vineyards on the Continent. There nothing is better ascertained than that the same variety of Grape produces wine of very different quality, according to conditions of soil and situation. For example, a certain variety of the Grape when grown on the Rhine furnishes a species of hock; the same Grape when raised in the valley of the Tagus yields *Bucellas*; whilst in the island of Madeira it produces the wine known as *Sercial*, which has a flavour quite different from either of the others. Soil also affects the time of ripening of the fruit, and in some of our colder and most sunless districts this fact is worth taking into consideration. At Thomery, Grapes are said to ripen a fortnight earlier in the flinty soils than they do where the soil is deeper and richer. I have observed myself that fine crops were produced, and had been produced for years I was told, from Vines where the soil was not above 15 in. or 16 in. deep. According to Prof. Solly, the Vine-producing soils of Thomery gave 81 per cent. of silica, 7 of alumina, and only $3\frac{1}{2}$ of organic matter. Such a compost with us would be reckoned very poor indeed. In this country most Vine-growers advocate a percentage of organic matter equal to, if not in excess of, the inorganic. No doubt such composts produce good crops, for a while at least; but I imagine that in a soil like that at Thomery the Vines would last longer, and produce better flavoured fruit.

A significant feature of Grape culture in England is frequent replanting. Here and there you may find Vines that have been going on for a good number of years, bearing and doing well; but I could point to instances where the work of replanting had to be begun soon after the Vines had reached the tops of the rafters—a practice that may do well enough when the means and accommodation and other circumstances render it practicable, but not one in a hundred can follow it; hence the way to get good crops of Grapes from the same Vines for the longest period is what we need to learn. In the poor soil at Fontainebleau and Thomery the Vines certainly carry as heavy crops as are found under the highest culture in private gardens here; but it may be doubted if Solly's analysis, as given by the late Mr. Robert Thompson, conveys a correct idea of the amount of nourishment supplied to the Vines, for I noticed that the borders were thickly mulched and surface-fed as well, although at the same time fine crops were to be seen on old Vines that were growing in the street, where the ground was paved closed up to their stems. Nor is the quality of the fruit and its maturation alone affected by soil; there is good reason to believe that the fertility of the plant is also much influenced. It is a well-ascertained fact that some Grapes bear well in some places and ill in others, after making every allowance for differences of culture. The *Barbarossa*, for example, is a shy fruiter in some soils and fertile in others; and the same may be said of the *Golden Champion*. Colour also is affected by the same conditions—some sorts colouring always well in certain soils and not in others. My impression of the *Grizzly Frontignan* is that it is a Grape that cannot colour perfectly; it only becomes red. In some cases it gets as red as a good *Red Hamburgh*, and in others the berries are only streaked with red, remaining partially green; and both samples are always about equal in quality, but, if anything, the darkest coloured samples are the best. The finest example of this Grape I ever saw as regards size of bunch, berry, and flavour was much darker-coloured than usual. That Pears and Apples and other fruits are affected by the soil in which they grow there can be no doubt, but it is perhaps more apparent in the Strawberry than anything else. In one place I could grow and force Keen's Seedling Strawberry better almost than any other, and thought most of it for forcing purposes; but here I cannot get a crop worth gathering from it, either indoors or out, though I have persevered with it in every possible way for years. Our neighbours on the same formation have failed with it also, and it is not now grown by us. When forced it makes a fine plant, but proves absolutely barren. J. S. W.

Vicomtesse Héricart de Thury Strawberry.—Some of your readers may remember the introduction of Keen's Seedling Strawberry, which became such a favourite that it was sometimes known as the "gardener's friend." Then there came trooping at its heels, Alice Maud, President, and a host of other good kinds, and now there has appeared in our midst the Vicomtesse Héricart de Thury, which is unquestionably the queen of Strawberries. There is no variety with which I am acquainted that can at all equal it. It has a vigorous constitution, grows like a weed, keeps ever-green all the winter, crops heavily, sets its fruit freely, and is not subject to mildew.—BETA.

THE CHILI STRAWBERRY.

ALTHOUGH the Chili Strawberry is known to fruit growers generally, it is not much patronised in the Paris markets, where it has great difficulty in maintaining its place against other kinds, and even then more on account of its size than for any other reason. Its principal

Chilian Strawberry.

merits are its lateness, and especially the firmness of its flesh, which allows it to be transmitted to great distances without fear of damage. As its name indicates, this Strawberry is a native of Chili, from whence it was introduced into Brest at the beginning of the eighteenth century (about 1712) by a French naval officer, whose

Chilian Strawberry (Flowers).

name, according to the "eternal fitness of things," was Frézier, the French for the Strawberry plant being *fraisiér*, which is pronounced exactly in the same way. Be this as it may, one thing is certain, that it has, so to speak, localised itself at Plougastel, in Brittany, on a kind of promontory a few miles from Brest, from which it is only separated by the bay. Here, close to the seashore on a granite soil,

it has flourished for more than a century. One peculiar fact in relation to this plant is that it has fixed itself at Plougastel, where it grows in the greatest perfection, and that it will not grow elsewhere. Whether this is owing to the peculiarities of the climate and soil of Plougastel or not we cannot say; but whenever attempts have been made to grow it in other localities, either in Brittany or in other parts of France—for instance, at Angers, Tours, Nantes, &c.—it has always proved a failure. Shortly after it has been planted it becomes sickly, it refuses to blossom, languishes, and finally dies. Even at Brest, where the climate and soil do not perceptibly differ from those of Plougastel, this capricious Strawberry refuses to grow for any length of time, and it can only be made to blossom by great care and attention. These details were gathered from M. Blanchard, the head gardener to the Naval Hospital at Brest. Thanks to this clever horticulturist, who is also a good botanist, we were afforded the opportunity of visiting the Plougastel Strawberry beds, and in his company obtained the information which we now lay before our readers. The Strawberry beds which we visited were those belonging to one of the principal growers of the locality, M. Barozer. The method of cultivation at Plougastel differs but little from that adopted in other localities, except that some of the growers plant on ridges separated from each other by a trench. M. Barozer, finding that the demand for the Chili Strawberry remained steady, has conferred a benefit on this part of the country by introducing a number of varieties which are better known and appreciated by fruit buyers.

The Chili Strawberry is a sturdy-looking plant which throws out large quantities of runners thickly covered with woolly down. The leaves only differ from the ordinary kinds by the great length of their stalks. The flowers are few in number, are borne on an upright stalk, and are of a yellowish-white hue. The fruit is very large, stumpy in shape, and of a pale glossy red, approaching vermilion in tint. The flesh is firm, the fruit being somewhat compact in texture; it is sweet yet a little sub-acid. The question may be asked whether the Chili Strawberry can be cultivated elsewhere than at Plougastel. Undoubtedly it may, but the climate and soil of the localities chosen must resemble those of Plougastel, which is close to the sea-shore and on a granite soil. In any case, the advantages to be gained by growing this Strawberry are not too apparent. We do not know whether any seedlings of this plant have ever been grown, but it is from this point of view that this variety would be most valuable. Experiments should be made in this direction with the object of determining whether it is possible to cross it with other varieties that do not possess its special characteristics. It should be crossed both ways with some of our luscious fine-flavoured varieties that are only found wanting in their weakness of growth. The Chili Strawberry plant gives abundance of fruit during the months of July and August, when the inhabitants of Brest and its neighbourhood may be said almost to live on Strawberries, devouring them literally morning, noon, and night. The Plougastel Strawberry furnishes us with an additional example of the benefit to be derived from the successful acclimatisation of a foreign plant.—"Revue Horticole."

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Setting Melons in Frames.—In a dull season like the present, if the fruit does not set freely, the best course is to withhold water for a time till a sufficient number are set. The process of setting (as it is commonly called) is very simple. Some may use a camel's-hair pencil, but it is not necessary; in fact, I don't think I have ever seen a pencil used by a gardener for setting Melons. The common way is to look over the frames some time between the hours of twelve and two o'clock, or any time when the pollen is quite dry. Select a mature, pollen-bearing flower, and split the corolla down one side with the finger and thumb. It will easily tear away from its base in the calyx, leaving the little cluster of stamens with their dusty points round the centre fully exposed. If this is brought in contact with the centre of the flower at the end of the fruit, so that the pollen is discharged, there will be no trouble about getting a crop of fruit to set. But sometimes the young Melons turn yellow, and decay before the flower is open; they do not seem to possess sufficient vitality to open their flowers. This is usually the result of planting in light, rich soil, which causes too luxuriant growth for fruitfulness. Melons never thrive well in light soil, placed loosely in the frame. Good sound loam, pressed in firmly, will always give short-pointed growth and robust-looking fruits, with plenty of pollen-bearing blooms. At this season Melons are frequently set by the aid of insects. As they travel from flower to flower they carry the pollen on some part of their bodies, and in this way the fertilisation takes place; but it is not wise to trust to the erratic motions of insects for a crop of Melons.—E. H.

Choice Plums.—Few of the domestic fruits are of so much service to the community as the Plum. It produces one of the most wholesome and delicious preserves, which improves with keeping, and when cooked fresh from the tree, Plums are always popular. In parts of Germany the Plum forms almost the staple food of the country. The Belle de Louvain, a red Plum, was received from Belgium many years since, but except from the fact that its name indicates its birth-place, I cannot find that it has any particular history. The tree is hardy, forms a handsome pyramid, and produces very large crops. It no doubt belongs to the numerous race of Red Magnum Bonum Plums, but it ripens earlier than the old sort, preceding the Victoria, which it rivals in fertility. The fruit hangs firmly to the branch, and is not easily shaken off. Boulouf is a very valuable bluish black Plum. It has been here for many years, under the name of Reine Claude de Jodoigne, and was received from a Belgian nursery. In the "Fruit Manual," Reine Claude de Jodoigne is described as a Greengage, and Boulouf as a cooking Plum. The Boulouf agrees with the description given in the "Journal of the Société Van Mons," vol. i., p. 298: Fruit large, round, dark purplish-red; flesh yellow, juicy, and perfumed, of the highest quality; ripening at the end of September. In addition to these excellent qualities, the tree is a robust grower, but very dwarf in habit, and therefore eminently adapted for garden-culture. Last year (1878), this Plum ripened the last week in September, and was certainly delicious, having all the sprightliness of the Purple Gage.—T. FRANCIS RIVERS, in *Florist*.

The Blistering of Peach and Nectarine Leaves.—Some cultivators, notably I think the Rev. Mr. Radelyffe, profess to prevent blister and to cure it. I confess it is wholly beyond me both as to cause and cure. This spring, for example, our trees passed through the flowering and the early growing stages without speck or flaw. Under a judicious screen of loose boughs they held their blossom, set a crop, and also made clean growth. All at once about three weeks since, the curl overspread them almost in a single night, as if it had been the plague—and it is the plague of the trees, the partial or complete ruin of their beauty for months, and probably also the destruction of next season's crop. Last year we were almost free from blister; this season we are literally overrun with it, and yet it did not follow on the heels of any very severe frosts. Nor were the aphides the producing cause. The blister seemed rather to come first to provide them snuggeries. The fly was several days behind, not in advance of the blister. In fact, I do not believe in the fly as the cause of blister. Coincident they often are—cause and effect never. How otherwise can we account for the fact that aphides are powerless to blister Peach leaves under glass? It would be well to know some of the causes, as it might suggest a more certain method of cure. It may probably arise from stagnation of sap. But that only removes this matter one step further. What practical cultivators want to know is, what causes or what will prevent such stagnation. Can any one tell us?—D. T. FISH.

Fruit-growing at Heckfield.—Readers of THE GARDEN who study the eminently practical remarks of "W. W." on fruit and kitchen gardening from week to week, will learn with interest that what is there so well inculcated is most successfully practised at Heckfield. There are eight Vineries at this place; in the first, a Black Hamburgh house, the crop is just ripe; the last is the Lady Downes house, a span-roofed structure, which produces annually about 6 cwt. of fruit, the bulk of which ripened in September, is cut in January, stored in the Grape-room, and continues to furnish an abundant supply up to the end of May, a period of eight months from the time of ripening. No greater testimony of the value of a Grape-room than this could be given, especially as the Grapes at the end of May are as fresh and plump as when cut. In this house the curious phenomenon may be seen of Vines rooted at both ends; the Vines planted on one side are carried over the roof and rooted at their extremities. In one case a rod has been severed about 6 ft. from the point, and thus is seen the still rarer phenomenon of a plant growing and producing fruit in a perfectly healthy condition through roots existing at its branch extremities only. This experiment might furnish useful hints to those physiologists who are disposed to study the vexed question as to the flow of the sap. Three houses are wholly devoted to Muscats, all in fine condition; some young Vines in a span-roofed house promise to produce noble bunches. In another low house are single or duplicate Vines of Barbarossa, Alicante, Gros Colman, Venn's Muscat, White Tokay, and others; all these are carrying fine bunches. Another house is furnished with a mixture of late sorts, and the big Camellia house has on its roof a grand crop of Hamburghs. There are three Peach houses (two forced and one cool), all full of fruit, and also a fine crop on the walls outside; and the same may be said in reference to Apricots and Plums. The earliest Peach house is a low span-roofed structure some 50 ft. in length, forming over the centre path a perfect arbour of foliage and fruit—the earliest just ripening. Low houses and pits are devoted

to Pines, Melons, and Cucumbers; of Melons the kind most largely grown now is the Earl of Beaconsfield, a handsome green-flesh kind that possesses first-rate flavour. Only one house is devoted to Figs, the one tree that covers the whole of the roof of a lean-to house, producing a succession of fruit for several months. Here ammonia, arising from cow manure that is spread on the border, renders the atmosphere somewhat unpleasant, but it is most healthful for the foliage and fruit. Outside there is a heavy crop of Pears, both on walls and pyramid trees, and also on curved cordons that form a graceful roofing to the centre garden walk. All bush fruits are abundant. A large tree of the Deux Ans Apple growing in one corner of the garden will probably produce about ten bushels of fruit.—D.

THE FLOWER GARDEN.

LIFTING RANUNCULUS ROOTS.

In the days when this beautiful plant was more grown as a florist's flower than it is now, the exact time for and mode of lifting were matters of some import. It was in the days when a good deal of enthusiasm was aroused over what the late Dr. Horner termed "a flower of extraordinary characteristics, uniting in itself properties and endowments of rare and opposite combinations. For we may say of it that it is grand, yet elegant; generous, yet simple; dazzling to behold, yet lovely to look upon." There are some who yet grow the Ranunculus, but they are few as compared with those of a quarter of a century ago. More's the pity, for it is a flower well worthy the high praise which Dr. Horner lavished on it. The taking up of the roots was always regarded as an important operation. If this be driven off too late, it used to be said there was a danger of their putting forth new fibres; an untoward circumstance, which either prevents their flowering the following year, or else destroys them altogether. On the other hand, danger besets the cultivator if the roots are harvested too soon, as the roots pine and shrivel, and bloom weakly; and yet, of the two, this was considered the lesser evil. This was the rule observed in the old days—as soon as the foliage, together with the flower-stems, had turned yellow and withered, it was considered that the roots were ready for lifting; and rather than any risks of new growth should be incurred, it was thought better to remove those indicating that appearance than to wait till the whole were ready. Those who grew for exhibition used to cover their beds with an awning or some such erection, using it to shade the plants when in flower, and this awning was brought out again as a useful and necessary precaution, when the weather, two or three weeks after the flowering period, became warm and showery; but leaving the sides exposed, as by thus keeping off the wet the disposition of the roots to make fresh growth was thereby counteracted.

When the tubers are lifted they should be placed in an airy cool room or shed, where they can be spread out, so that the soil on them might dry gradually. They should be turned over occasionally, especially in damp close weather, so that mildew does not lay hold of them. As the Ranunculus is increased by division of the roots, this process should be performed when they are about half dry, as they separate easily, and the soil can be cleared from the roots without injury. Each sort should be placed in a box, or in one of the divisions of a drawer, or some such place, in a cool dry atmosphere, and kept till planting time comes round again. Collections of named Ranunculuses are not difficult to procure. Mr. Carey Tyso, of Wallingford, still grows this charming flower in quantity, and it is stated there is yet a good demand for named varieties. R. D.

The Striped Forget-me-not.—This, called Weirlegh Surprise, I have grown in quantity, and a fine pot of it was among Mr. Brockbank's herbaceous plants at Manchester. Its flowers are singular and pretty; though the plant is somewhat straggling, it is permanent when produced by means of cuttings, and I should say it is a cross between the blue and the white forms of the *Myosotis*.—THOS. WILLIAMS, *Ormskirk*.

Gladioli in Rose Beds.—During last winter we took up and replanted most of our dwarf Roses, having previously prepared some fresh beds for their reception by heavily manuring and deeply cultivating them, and, having a quantity of fine Gladioli bulbs, I planted them in the open spaces between the Roses; they have made excellent growth and promise to be a source of great attraction after the principal bloom of the Roses is over; the foliage, being erect, does not at all injuriously affect the Roses. I intend to allow them to remain permanently, just covering the crowns in winter with Cocoa fibre or coal ashes, as, like many more of your correspondents, I find Gladioli to do best when left in the ground, or if lifted for dividing, the bulbs should be replanted as soon as possible.—J. GROOM.

CHARACTERISTICS OF THE FLORIST'S TULIP.

THE BREEDER.

THE Tulip is perhaps one of the most precious of flowers in the estimation of the florist, because of the extraordinary transformations through which it passes, as well as on account of its possession of other qualities of a not less fascinating character. One singular peculiarity of the Tulip is the extraordinary change which takes place when the seedling breeder "breaks," or, in other words, assumes its proper and permanent character. That a flower which, on its first blooming from the seed, and probably for a series of years afterwards, should (to take the case of a fine Byblemen) present but one dull slate colour with a circle of white at the base; that this flower, so unattractive in its appearance, should all at once, without any apparent cause, completely alter its nature; that the dull slate colour should disappear entirely, giving place to a delicate feathering of rich purple or violet, while the pure white, which was confined to a narrow circle at the base, should spread all over and become the ground colour of the petal; and that the latter and true character should be maintained during the whole of the after existence of the plant, is surely so remarkable a fact in vegetable physiology as to deserve at the hands of the scientific and practical botanist the closest investigation.

Many persons, though well acquainted with flowers, are unaware of the changes through which the seedling Tulip passes. It is four or five years before it flowers, then it takes on the self-coloured or breeder form; but in the breeder state it is easy to class it with the Bizarres, Roses, or Byblemens, according as it may belong to either of these three divisions. Then, at the expiration of sometimes one or two years up to six and seven years, it breaks into its true character, and becomes what is termed "rectified." Why the Tulip should be an exception to the universal law observed in seedling flowers, and have an almost exceptionally intermediate state, passeth knowledge. The practical florist asks of the botanist the why and wherefore of this, and no reply is forthcoming.

It is said that in the whole range and history of plants there is no analogy to this phenomenon. Other flowers will occasionally sport, and blooms will vary in character from the effect of seasons or culture, but these are accidental variations, and although a "sport" may sometimes become permanent, such an incident is to be regarded as an exception to the general rule. The Tulip alone has naturally, and according to the law of its being, two distinct stages of existence: first the breeder state, in which the petals are, excepting the circle of white or yellow at the base, of one dull colour throughout; and, secondly, its broken or perfect state, when it becomes smaller, shorter, and less robust in its growth, and the colour, instead of being dull and diffused all over like a field Poppy, is concentrated on the edge or centre of the petal into brilliant stripes and feathering so sharply and finely cut that the engraver's skill can scarcely do justice to it. No one, however careless an observer of the workings of Nature, can fail to be struck with this wonderful metamorphosis on first being shown a bed of breeders side by side with a bed of broken flowers; and yet, wonderful as it is, it seems to have failed in attracting the notice and enquiry of the many distinguished men who have devoted themselves to the study of plants.

The readers of THE GARDEN will now be able to understand a little better perhaps than before what constitutes a "breeder" Tulip. In all Tulip exhibitions they form a part, for in the breeder state some of them are very beautiful indeed when thoroughly pure, finely coloured, and of good form. But when these beautiful breeders will break into the rectified form—when the floral chrysalis shall develop into the brilliantly-marked butterfly—is not given to men to know. It may be next year; it may not be till the grower has added three or five to the number of those he has devoted to his favourite pursuit.

R. D.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

The White Japan Anemone in the Wild Garden.
—Few plants are more lovely in the wild garden than this, and few more suitable for such purposes. The idea of the wild garden first arose in the writer's mind as a home for a numerous class of coarse-growing plants, to which people begrudge room in their borders, such as the Golden Rods, Michaelmas Daisies, Compass Plants, and a host of others which are beautiful for a season only, or perhaps too rampant for what are called choice borders and beds. This is one of the most beautiful of garden flowers, and one which is as equally suitable for the wild garden as the kinds alluded to. It grows fairly well in any good soil in copse or shrubbery, and increases rapidly. Partial shade seems to suit it, and in any case the effect of the large white flowers is, if anything, more beautiful in such places. We have also noticed the flowers to be more lasting than in places where they are fully exposed.

Miniature Flowering Plants.—Cuttings of the leading or well-developed side shoots of *Eranthemum pulchellum* will strike now in bottom-heat, and will soon form very neat and useful little plants, carrying large clusters of flowers, although themselves only a few inches high. The time to take the cuttings is just when the growth is completed and partly ripened—when, in fact, the flowers are in an embryo state, but not visible. In the case of the plant which I have mentioned, the season to take the cutting is about now. Rather large pieces, comprising the ends of the leading shoots, may be taken, and inserted singly in small pots of sandy peat, and be kept moist, close, and shaded from bright sunshine until rooted. Afterwards they may be subjected to the same treatment as the old plants. Miniature flowering plants of many other kinds may be propagated in the same easy way. The leading shoots of Balsams and Celosias may be struck in small pots in this way—the *Salvias*, especially the winter-flowering kinds, such as *splendens*, that are so useful for the conservatory; also very fine heads of *Hydrangea* blooms have been grown in very small pots in like manner. *Chrysanthemums* are well suited for flowering in a small state, in small pots, and may be obtained either by layering

The White Japan Anemone in the Wild Garden.

the ends of the shoots, or by striking them in a close, shady place. In fact, nearly all soft-wooded plants, after the growth is made and just beginning to get firm, can be made use of, if desired, by simply cutting off the flowering points of the shoots, and striking them in small pots. A very small amount of bottom-heat will suffice, even for stove plants; and others that have been grown in a cool structure, or perhaps altogether in the open air, will only require a cool, close, shady frame. Too much heat will unduly excite, and its effect will be either to force the flowers prematurely, or else they may be converted into growth. There are many uses to which such bright showy little plants can be put. They will carry the large fully-developed flowers of full-sized plants, and will be very valuable for filling stands in rooms; and if an imitation of a large plant is required, half-a-dozen plants of a kind grouped together will effect it.

—E. H.

The Blue Cornflower.—It is well known, in Germany at least, that the blue Cornflower is the Emperor William's flower and colour, and it is the practice to decorate his room with it on his birthday. If its cultivation has failed, Italy or France, or some other country, must furnish the favourite Cornflower, which, in a sense, has become the rival of the Napoleonic Violet; and these two flowers are unfortunately not exactly friendly rivals, like the light blue of Cambridge and the dark blue of Oxford. After the late dastardly attack on the Emperor's life, the Cornflower became the emblem of loyalty and devotion of the Prussian people. Ladies wore Cornflowers in their hats, gentlemen in their button-holes; medals bearing the Emperor's effigy on one side, and a wreath of Corn-

flowers on the other, were worn in bracelets and necklets; note paper was decorated with the favourite flower; in short, it was employed in every conceivable way to testify the loyalty of a people.

Lobelia Lady McDonald.—This is a useful variety, with large blossoms of a pale but pleasing colour. It is somewhat straggling in habit, and looks extremely well for edging vases or hanging baskets, being a most profuse bloomer.—J. G.

Double Zonal Pelargonium Vesta.—This fine variety, raised by Mr. Laxton and awarded a first-class certificate by the Royal Horticultural Society, is somewhat in the way of Wonderful, but brighter. Its foliage, which is deep green, is ornamented with a well-marked dark zone. It will prove a useful kind both for the purposes of ordinary decoration and for market.—M.

Varieties of Lily of the Valley.—We notice a great variety in the habit and strength of these, as shown in Ware's nursery, Tottenham. There are a great many varieties differing much in the size of the foliage, and the size of the flower bears generally an almost exact relation to the size of the leaf. These are important facts for all who love this beautiful plant, and will no doubt lead to the large varieties being much sought for.

Sempervivum Pomelli.—With reference to the *Sempervivum* at St. Alban's Court to which Mr. Williams (p. 512) refers S. Pomelli, I think that he is wrong, as, according to Mr. Baker of Kew, S. Pomelli is a species very near S. piliferum or S. fimbriatum, and instead of being simply distinguished from S. arachnoideum by the tuft of wool at the tip of each leaf, it is quite a different plant and distinct from S. arachnoideum.—E. JENKINS, *Newton Nurseries, Chester.*

Irises in a Cut State.—What beautiful shades of colour one sees amongst Irises! Spikes of them cut and put in vases, garnished with a little delicate foliage, are even more effective than the choicest Orchids, both as regards form and colour. Irises are gradually coming to the front again, and it is well they should do so, if for no other purpose than that of supplying flowers in a cut state.—J. G.

Mud Edgings on the Thames Embankment.—Can anyone explain the object of these? I see them bare and hard in the gardens here, some of them nearly 1 ft. high, with a few plants straggling over them. Surely this habit during a considerable portion of the early summer tends to make a bed stiff and curious looking. The practice is an ugly one, but it may have some advantages, and, if so, I should be much obliged to any reader to state them.—COUNTRY VISITOR.

Veronica Traversi (syn. *devoniensis*).—This is one of the most useful plants in cultivation, forming, as it does, neat, symmetrical evergreen bushes 3 ft. in diameter, now completely smothered with delicate white racemes of flowers. For the centres of beds or for isolated positions this *Veronica* is simply unique, and it is one of the finest plants that can be planted in suburban districts, having withstood the severity of the past winter uninjured. In habit it is free, and readily propagated by means of cuttings taken in autumn when the wood is ripe. They should be dibbled in pots and placed in a cold frame during winter. It can also be grown as a pot plant for windows, and it can likewise be utilised in many other ways.—R. A. J.

Bedding Pansies.—The telling effect of colour produced by masses of particular hardy plants has been well illustrated this season in Mr. Cannell's nursery at Swanley. This is especially apparent in the case of bedding Pansies which are grown here in very large quantities, individual varieties occupying breadths sufficient to be most striking, not only upon near inspection but also at a considerable distance off. Most conspicuous in this way were Celestial Blue, Blue Gem (plum colour), Yellow Boy, purpurea (pale mulberry), and Chieftain (medium shade of blue). The dwarf growing Wallflower Harbinger was a compact, even sheet of colour, contrasting well with the pale blue *Veronica gentianoides variegata* and its white variety.—P. G.

Hardy Flowers at Huntingdon.—The best cut hardy flowers I have seen were exhibited by Messrs. Wood & Ingram at the Huntingdon Show. The arrangement of them was most tasteful, the colours being skilfully contrasted, and each species or variety was set up in a loose, natural manner, showing its habit of growth, and with as much foliage as possible. Too often the effect of exhibitions of hardy border flowers is destroyed by the unskilful way in which the bunches of flowers, as they are called, are huddled together, often without any regard to the effective arrangement of the colours, large bunches of the very commonest plants frequently hiding and smothering the few choice flowers that the collection contains. The following is a list of the flowers in the stand to which I am referring, viz., *Scilla peruviana alba*, a fine, robust spike; *Pyrethrum Progress*, the double variety of *Spiræa filipendula*, *Stenactis speciosa*, *Potentilla Etna*, a darker kind very bright and effective; *Allium Moly*, a fine yellow-flowered border plant; *Centaurea*

cœrulea, white Pink, *Veronica candida*, *Iris Xiphoides*, *I. Priscilla*, *I. ventricosa*; *Delphinium elatum*, *D. Wheeleri*; *Lilium auratum*, *L. colchicum*, *L. longiflorum*; *Campanula persicifolia alba*, *Antirrhinum majus*, *Aquilegia chrysantha*, *Pæonia Whitleyi*, *P. albiflora fragrans*; *Veronica saxatilis*, and *Gladiolus byzantinus*. I have never seen any stand of greenhouse cut flowers that could vie in beauty with those of our best hardy plants when properly set up, as they were in this case; and in this age of room and table decoration I know of nothing so likely to bring them back into favour as the proof afforded by such exhibitions of the great value which hardy flowers possess for cutting. E. HOBDAV.

Transmission of Plants.—Everything grown under glass at the Swanley Nursery is of a soft-wooded character, plants mainly that can be propagated quickly, fit for sale in a comparatively small state, which very much reduces the size of packages, and consequently cost of carriage, for in most cases the pots are not sent; transmitted in this way, without pots, even over very long distances, plants of this description are found to carry well, as there is little liability to bruise. Cuttings, or newly-struck plants, in which a large trade is done here, are mostly sent in shallow tin boxes through the post; so enclosed air is excluded and evaporation is reduced to a minimum. The cuttings when received are fresh and plump, a condition which people who have had to deal with flagged cuttings will know how to appreciate.—P. G.

Hardy Plants at Sydenham Hill.—Sheltered from the bleak north and easterly winds few suburban gardens are more favourable for the luxuriant growth of plants than that of Mr. Latimer Clarke, and equally few there are to be found where so much has been done to render a garden beautiful by the introduction of hardy exotic plants. When we visited it the other day the sloping banks were covered with huge clumps of *Rhododendrons*, *Azaleas*, and other shrubs in flower, whilst on the lawns beds were gay with the finest hardy flowers, which formed a striking contrast to the tender bedding plants recently placed in the adjoining parterres, for the well-being of which the present ungenial weather is anything but favourable. Wild gardening is a prominent feature here, and those only who have seen for themselves can fully appreciate the charms afforded by groups of hardy plants when left undisturbed. In a sheltered nook, growing in a peaty soil kept moist by the drainage of the high ground above, was a mass of *Cypripedium spectabile* with stems fully 2 ft. high, each bearing a couple of blossoms varying in colour from almost white to a deep rosy-magenta. Creeping over the surface and thriving with native vigour was the pretty little Ivy-leaved Hare-bell (*Wahlenbergia hederacea*). In the same position the swamp Lilies of North America (*Lilium californicum*, *superbum*, &c.) were thriving admirably; the moist peaty soil and the protection afforded to the young growth seems indispensable to their successful culture. Other kinds of Lilies, such as *L. umbellatum*, *elegans*, and similar species revel in the stiff loamy soil in the less sheltered positions where they have grown for years undisturbed, and the large size of the specimens and the unusual number of flowers which they bear constitute ample proof that to be successful with them these conditions must be imitated. A rocky natural-looking in style is one of the leading features of this place. It is built of huge masses of rock, and is of considerable height; from its top a stream of water constantly trickles down and feeds a pool below in which a choice collection of hardy aquatics is thriving well. Amongst the latter we noticed the rare *Orontium aquaticum* finely in flower. The beautiful mountain *Clematis* (*C. montana*) rambles over the rocks along with other shrubs and herbaceous plants, and is gay with its white, starry blossoms. A choice collection of Alpine plants is grown here in pots, and the thriving tufts is sufficient proof that pot culture, in some localities, is preferable to planting on rockeries, &c. The rarer of the crustaceous section of Saxifrages, such as *S. casia squarrosa*, *valdensis*, *luteo-purpurea*, &c., as well as *Androsace Laggeri*, *obtusifolia*, *Chamejasme*, *pyrenaica*, and others, thrive remarkably well under this treatment, as does also the pretty *Linaria organifolia* and *Houstonia cœrulea*, which in some gardens refuses to grow. The Alpine *Dianthus*es (*D. alpinus* and *gracialis*) Mr. Clarke grows admirably; also the *Edelweiss* and the beautiful *Onosma taurica* and *echioides*, which require to be kept rather dry during winter. One of the brightest-flowered plants in the collection was the scarlet *Ourisia* (*O. coccinea*), which is not often met with in good condition. Amongst the larger-growing kinds in flower, the rare *Eremurus spectabilis* was conspicuous. It is somewhat in the way of *E. robustus*, but scarcely so robust in growth; the flowers, which are membranous and pinkish, are borne on branching spikes from 5 ft. to 8 ft. high. W. G.

Culture of Alpine Plants.—At a late meeting of the Scottish Horticultural Association, Mr. Sutherland remarked that he had found Alpines from high altitudes more difficult to manage than those from lower levels, and he recommended such to be grown in

pots, and kept in cold frames or pits, so as to secure complete control over ventilation, shade, and moisture. He stated, however, that by far the greater number of species, and those by no means the least ornamental, were amenable to treatment as ordinary border or rock-work plants, where, under fairly favourable circumstances, they soon established themselves, and formed a permanent source of interest. In regard to rockwork he held that, provided good drainage could be secured, a low or even hollow site was preferable to such as was high and exposed. So far as soil was concerned, he had found a good loam the most generally useful—such species as required peat, peaty composts, or calcareous soils being comparatively few in number.

Hardy Plants in Flower at Sykeet.—There is much to interest the hardy-plant lover in such a garden as that of Mr. Stevens at Grasmere, not only on account of the abundant variety which an extensive collection always affords, but also on account of the unusual vigour exhibited by many of the plants grown there. To the Delphiniums, which form one of the chief objects of attraction, we have elsewhere alluded. Of the different varieties of *Iris Kämpferi* there are huge masses, in some instances 3 ft. high and as much through, affording proof sufficient that these beautiful plants require a friable, rich soil, well drained, and sheltered—conditions under which they are growing here. On the rockery, the showy *Coronilla iberica*, with its golden heads of blossoms, is flowering abundantly, and is certainly one of the most desirable of the dwarf members of the Pea family, and one which lasts long in perfection. *Malva campanulata* is another fine plant which is equally desirable. It has withstood the winter with impunity, doubtless on account of its well-drained position, and is now gay with pretty pink blossoms. Several *Acantholimon*s enliven the rockery at this season with their lovely membrane-like rosy flowers, which form a pretty contrast to such plants as the Mountain Avens (*Dryas octopetala*), with its pure white golden-centred blossoms and dense cushion-like tuft of leaves; also to the white-flowered form of *Campanula nitida*, a dwarf kind growing about 6 in. high, with numerous blossoms as large as a florin. The most noteworthy of the larger-growing plants were remarkably well-grown examples of the purple *Echinacea* (*E. purpurea*), which is one of the handsomest of the numerous Composites from North America. It grows about 3 ft. high, and has large solitary flower-heads, the outer florets of which are of a violet-purple tint, and droop gracefully. The large-leaved *Achillea* (*A. macrophylla*) is an uncommon as well as handsome species. It is a bold-looking perennial about 4 ft. high, with deeply-cut leaves about 1 ft. long, and broad flat heads 6 in. across, composed of numerous small white flowers, which are very attractive. It is a capital plant for the wild garden, or for places where it would receive no attention. Harebells are grown here extensively, and many of them are now in flower. The finest are *C. Van Houttei*, with long purplish bells, and its nearly ally, *C. nobilis*, with flower of somewhat the same tint as in the type, and pure white in the variety *alba*. The white-flowered variety of the Nettle-leaved kind (*C. urticifolia*) is remarkably handsome, and should be in every collection. The smaller-growing sorts are represented by large masses; *C. carpatica pallida* we noticed with several scores of flowers expanded on a tuft measuring 2 ft. across, and *C. turbinata*, one of the finest of all the species, thrives here with like vigour. The hardness of the *Hyacinthus candicans* has been well tested at Grasmere, where it has withstood the past winter unhurt, and is now developing spikes of chaste white blossoms. Another fine plant is the Olympic St. John's-wort (*Hypericum olympicum*), which is one of the most desirable of all the species; here it thrives capitally, and will soon form a mass (2 ft. across) of golden blossoms, which contrast well with its singular glaucous foliage. The Southern *Baptisia* (*B. australis*) is a very handsome plant in its ordinary condition, but a variety of it which we noticed here is far more desirable, as its flower spikes are much longer, and the purple colour of its blossoms of a much deeper shade, rendering it quite deserving of a distinctive varietal name.—W. G.

Himalayan Primroses.—These do wonderfully well at Ware's. Huge beds of them may be seen there with foliage more vigorous than Dock leaves. Hitherto these plants have been too much coddled in frames and in small pots, and in all sorts of positions which prevented their natural growth from being exemplified. In the place which we name they are in open quarters, and in stiff cold ground, liable to occasional floods.

Pinus macrocarpa.—As an evidence of the rate at which this Californian *Pinus* grows when soil and climate suit it, I may mention that the largest tree of it at Knap Hill was turned out of a small pot about 1839, and the stem now girths 10 ft. Its very distinct appearance when it gets large enough to show its true character commends it to the notice of planters.—P. G.

NOTES OF THE WEEK.

Mutisia decurrens.—There is at Kew, planted against one of the walls near Museum No. 2, a specimen of this beautiful climbing plant, bearing several flower buds which will shortly expand. When in flower it will be well worth a visit, for certainly it is by far the most charming of the Composite yet introduced from the Chilian Andes. Nothing can well surpass the beauty of its large bright orange-tinted flower-heads, with their gracefully-drooping, long, narrow, outer florets borne on slender twining branches; the latter being furnished with glaucous green foliage considerably enhances the bright effect of the flowers.

Kniphofia caulescens.—An admirable specimen of this handsome hardy perennial is now in flower in Mr. G. F. Wilson's garden at Weybridge, where it has withstood the past winter with impunity. Its thick stem, terminated by bold glaucous leaves, arranged in a Yucca-like manner, renders it very distinct from any of the other species, though in the style of flowering and colour of the blossoms it is somewhat similar to several of the better-known kinds. The flower-stem of the specimen in question is about 5 ft. high, though in a wild state it attains a much greater height.

Lilium Japonicum Colchesteri.—This scarce and handsome Lily has recently flowered in Mr. Bull's nursery. It is a fine kind in the way of *L. Browni*, but creamy white.—P. G.

The Moccasin Flower in a Small Pot.—Mr. Burbidge has recently shown us a plant of this *Cypripedium* growing in a 5-in. pot in a window. The soil in which it is placed is very moist, and surfaced with a little carpet of Penny-leaf (*Hydrocotyle vulgaris*).

Double White Ragged Robin.—This interesting old plant we noticed at Ware's the other day. It is a very uncommon one in England, and one which will doubtless be sought after by lovers of curious hardy flowers.

Lælia purpurata.—A flower of this *Lælia* sent to us by Mr. Boxall, Claybury Hall, Chigwell, shows a singular monstrosity. One of the sepals has assumed the form of a lip, as have also the two petals, while the lip proper retains the normal condition.

Double Marsh Marigolds.—There are several kinds of these in cultivation, differing from each other in a remarkable degree, both in habit and strength. We noticed them at Ware's the other day. Such plants would be very beautiful on the margin of water, or in moist ground.

Early Rivers Cherry.—Fruit of this Early Black Cherry has been sent to us from Sawbridgeworth, and very large and handsome it is. The tree, which is an abundant bearer, is a seedling from the Early Purple Gean. It received a first class certificate from the Royal Horticultural Society in 1872, and is certainly one of the best of early Cherries.

Dracænas and Eucalypti.—We have here two *Dracænas* (*australis*) about 16 ft. high, out-of-doors, and in flower. One has a magnificent spike, the other is deformed; they have survived the winter without protection. *Eucalyptus globulus*, from seed sown five years ago last April, is 32 ft. high, and although the foliage was very much browned last winter by the frost, it is breaking into growth strongly.—W. HILLS, *East Cowes Castle, Isle of Wight*.

Calochortus venustus.—As an instance of large size attained by skilful cultivation, we noted an unusually fine specimen of this beautiful Mariposa Lily growing in Mr. Wilson's garden at Weybridge. The stem measured 2 ft. 7 in. in height, and the blossom $5\frac{1}{2}$ in. in diameter, which is by far the finest example of this with which we have yet met. Mr. Wilson grows it in deep pots in one of his Lily houses, treatment which evidently suits its requirements.

The Vine-leaved Passion Flower (*Passiflora vitifolia*).—This is one of the most brilliant Tropical climbers with which we are acquainted, and nowhere have we seen it grown so successfully as at Mr. Parker's nursery at Tooting, where we recently saw it in full flower. Its blossoms, which are much larger than those of the commoner kinds, are of a bright vermilion hue, a colour which contrasts admirably with the deep green leaves, which are, as its specific name implies, of the shape of those of the Grape Vine.

Stigmaphyllon ciliatum.—Though an old introduction this beautiful climbing plant is one of the most satisfactory for stove culture as it never fails to flower annually in profusion for a considerable period, and moreover, it is apparently exempt from the attacks of insect pests which usually infest stove climbers. It is of a slender twining habit with heart-shaped leaves, beset with a row of hairs at the margin. The flowers are produced in loose axillary racemes, and are about $1\frac{1}{2}$ in. across; the petals are fringed at the edges, and are of a clear bright yellow colour. It is now one of the most conspicuous plants in the Palm house at Kew.

Habenaria fimbriata.—This, commonly considered to be among the curiosities of hardy plant collections, proves to be a very lovely Orchid, and when well established it is almost as handsome as *Orchis foliosa* and more striking. We have lately noticed it very well grown at Ware's.

Iris Kämpferi.—This Iris and its varieties are now flowering profusely in Mr. Barr's grounds at Tooting, where there are plants sufficient to produce from 1000 to 2000 blooms, thus furnishing an unprecedented display. One variety, of a rich claret colour, has flowers measuring 7 in. in diameter, its broad falls giving it more the appearance of a large-flowered *Clematis* than an Iris. English Irises are also flowering abundantly just now in the same grounds.

Singular Orchid.—We lately saw in Mr. Bull's nursery a remarkable Orchid in flower, supposed to be an *Habenaria*. The flowers are completely wrong end up, like those produced by *Odontoglossum pulchellum*. The lip is white, the sepals and petals green, and about 1 in. in length. Along with it was also in bloom the singular *Oncidium dasytyle*, the lip of which is pale primrose, and the sepals and petals are spotted with green. It is a small-growing, very uncommon looking plant, the flowers of which are extremely distinct.—P. G.

Handbook to the Flora of Germany.—Under the title of *Deutsche Excursions-Flora* Dr. Carl F. W. Jessen has published a convenient summary of the German flora, including Holland and the whole of Germany and German Austria, north of the Alps. By means of a condensed typography and an elaborate series of signs a great amount of information is comprised within small compass, including even mention of the principal hardy garden plants.

Flora of Japan.—The third part of the second volume of Franchet and Savatier's *Enumeratio Plantarum Japonicarum* has appeared, thus completing this useful work. The first part was published in 1875, and the entire work runs to 1274 pages. Few botanical books have so much interest for horticulturists as this, treating, as it does, of the exceedingly rich vegetation of a country enjoying a climate similar to that of our own. Numerous as are the ornamental and useful plants we have in cultivation for which we are indebted to Japan, the vegetable riches of that region are by no means exhausted.—*Gardener's Chronicle*.

Park for Wolverhampton.—Twenty-seven competitors responded to the invitation of the Wolverhampton Town Council to send in designs for laying out as a public park 47 acres of land near the town. The first premium (£50) has been awarded to Mr. R. H. Vertegans, Chad Valley Nurseries, Edgbaston, Birmingham; Messrs. Barron & Son, Elvaston, near Derby, gained the second premium of £25. Mr. Vertegans has been engaged to lay out the park and plant the same in accordance with his design for the sum of £5000. The accepted design provides for spaces to be devoted to cricket, archery, croquet, and other outdoor games, a drill ground for volunteers, and a lake covering a space of about 9 acres. Some twenty thousand trees and shrubs are to be used in planting; and arrangements will be made for shelter, refreshment rooms, &c. Outside the fence of the park, and encircling it, there will be a spacious drive for carriages, &c.

Tuberous Begonias.—Few plants have become so popular of late years as these, and many fine-named varieties have been produced; but the great demand for them, and the somewhat slow way in which they are increased, tend to keep up their price. For ordinary decorative purposes very beautiful flowers can be had from seed, provided this is obtained from a really good strain: anyone questioning this would have his doubts dispelled by the sight of a large house at Messrs. Veitch's. Of this house one-half is filled principally with plants from seed such as anyone may obtain, and as we have said, for ordinary display these are all that need be desired; in colour they vary from pale creamy white through every shade of pink and salmon up to scarlet, red, and deep crimson. Their easy culture and long continued habit of blooming, and last, not least, all but immunity from insects, make them deserving of cultivation by everyone who possesses a greenhouse, pit, or even a large garden frame, as well as out-of-doors in moderately sheltered spots where they will not be much exposed to the wind.—P. G.

The Best Double White Fuchsia.—It would not be prudent for a cultivator to limit his selection of Fuchsias to two or three varieties, but some of the Fuchsias are so far superior to the others, as regards decorative purposes, that it is desirable to direct attention to them for the information of those who may not be desirous of growing a large number of plants, but a few of the best. Of the double varieties with white corollas, of which I have grown all that have been introduced of late years, the best is unquestionably Miss Lucy Finnis, which was sent out by Mr. Cannell a few years ago. The flowers are very large, the brilliant red sepals nicely re-

flexed, and the corolla, which is very large, consists of broad, flat petals, well arranged. Its greatest value, however, consists in the splendid habit and the profusion with which the flowers are produced; and in manner of growth and freedom of flowering it has but few equals and no superior. No better proof of its utility could well be had than the fact of its being grown largely for Covent Garden Market.—*Gardener's Magazine*.

PLATE CLXXXIX.

A GROUP OF HELLEBORES.

Drawn by CONSTANCE PIERREPONT.

HELLEBORES rank amongst the most ornamental of winter-flowering hardy plants, but, although, as will be seen by a glance at the accompanying plate, they possess considerable variety and diversity of colour, it is a singular fact that one seldom meets with any of them in gardens, except the ordinary Christmas Rose (*Helleborus niger*), though they are all equally amenable to culture; indeed, there is not a garden in which they will not thrive, provided they are planted in light rich soil and in a partially shaded situation. In Vol. XIV. (p. 178) of THE GARDEN, we gave a coloured illustration of the Giant Christmas Rose (*H. altifolius*), accompanied by a complete list and short descriptions of the species in cultivation. We, however, alluded but briefly to the many beautiful varieties that have been raised both in Continental and English gardens through skilful hybridisation and selection of seedlings. The principal named varieties belong to the group with purple flowers and thick, leathery, evergreen leaves. For the varieties figured we are indebted to Messrs. Barr & Sugden. These comprise—

Helleborus orientalis Dr. Moore.—A fine variety raised by the late Dr. Moore, of Glasnevin. It is an abundant bloomer of vigorous habit with greenish stems spotted with purple. The flowers are larger than those of the type, of a lively rose tint, with the edges and inner face of the sepals of a lighter hue.

H. orientalis rubidus.—The flowers of this variety are of a medium size, of a reddish-plum colour on the outside and paler within.

H. orientalis rubellus.—Another distinct kind, having flowers of a similar size to those of the preceding, but of a lighter shade produced by the glaucous bloom.

H. abchisacus ruber.—This is a darker-flowered form than the original, but in other characters it is similar.

H. rubro-purpureus.—A distinct and handsome variety in the way of *H. atro-rubens*, but with flowers of a much deeper shade.

H. guttatus Leichtlini.—A pretty variety characterised by copious spots on the inside of the flowers, and the latter considerably larger than those of the type.

H. fulvus.—This is a handsome seedling form of *H. atro-rubens*, of robust habit, but with larger blossoms. The latter are reddish-purple suffused with pale brown.

H. atro-roseus.—This is another seedling from *H. atro-rubens*, to which it bears considerable resemblance, though the flowers are paler in colour.

H. colchicus punctatus.—A very handsome variety, and one which is depicted in our plate. It is similar to *H. colchicus*, from which it differs by being copiously spotted with deep purple.

The varieties that have emanated from the continental gardens are

H. orientalis Commerzienrath Benary.—A pretty variety, similar to *H. guttatus*, and profusely spotted with deep purple spots on a greenish white ground.

H. orientalis Frau Irene Heinemann.—The blossoms of this form are paler in colour than those of the typical kind, but may be distinguished by the purple spots on their inner surface.

H. orientalis Hofgarten Inspector Hartwig.—Another variety of the orientalis group, but with less showy flowers, being of a dull purple hue.

H. orientalis F. C. Heinemann.—A form similar to the foregoing with the same dull purplish tint, but mottled.

Iochroma Warszewiczii.—A rare but free-growing Mexican plant, having viscid, dark green, oblong leaves and gracefully drooping axillary clusters of tubular flowers, which are of a deep blue colour and very effective. Its dense foliage and distinct appearance are in its favour as a pillar plant for a moderately warm and airy conservatory, and in such a one we have just seen it blooming well.—F. W. B.

GARDENING FOR THE WEEK.

Flower Garden.

The weather is so constantly cold and wet that flower gardens generally are in a deplorable state, and worthy of that designation in name only, flowers being wanting, whilst those plants that are used on account of the colours of their foliage only, such as Coleus and Alternantheras, refuse to make the slightest progress in growth; it therefore at present seems as if flower gardening will be a complete failure this season. Nevertheless, a week's sunshine would work a marvellous change. The hardier plants, such as Pyrethrum Golden Feather, variegated Mesembryanthemum, and Mentha Pulegium, have grown somewhat patchy, and should be cut or pinched back to the desired form. Verbenas, Petunias, Heliotropes, and Ageratums are growing straggly, and require pegging, in order to preserve uniformity of height and truthfulness of design. Herbaceous borders present a somewhat weedy appearance, many plants, such as Phloxes, Pyrethrums, and Asters, consequent upon the excessive wet and sunless weather, having made abnormally tall growths. All these require staking, and the borders generally must be weeded and hoed when the weather permits. Stake Sweet Peas, top back a few inches the earliest flowered ones, in order to induce a second bloom, and clip over, with the same intent, annual flowers that have produced a first bloom. Virginian Stocks, Scilanzhuses, Nemophilas, and Eschscholtzias are all of them amenable to such manipulation. In order to keep lawns in anything like trim condition double the usual labour is necessary this year, but as mowing cannot be postponed without injury to the finer Grasses, and as neatness makes amends for many other shortcomings, such labour need not be begrudged. Cutting Box, clipping hedges, pruning evergreens, and budding Roses may all now be done as time and opportunity offer.—W. W.

Auriculas.—We have this season reserved a considerable number of specimen plants from which to save seeds, but the harvest does not promise well except where the flowers were crossed with other varieties. I recently commented upon the best varieties to select as seed and pollen bearers respectively; there are many kinds that can scarcely be prevailed upon to produce a single seed, *i. e.*, if the flowers are only fertilised with their own pollen, but which will produce plenty if foreign pollen is employed. The seedlings from last year's seeds are growing very freely, and by taking care that the plants receive no check, we shall obtain several hundreds of good flowering plants for next season. 3-in. pots will be sufficiently large for the largest plants. We shall grow a goodly number of Alpines out of doors next season, and shall also try some of the others; they all will stand the winter, and flower quite as strong as plants in pots; the only drawback is the injury which the plants receive from rains, which spoil the beautiful foliage dusted with farina. The white and grey edged classes are the least suitable for out-door culture. Now is a good time to plant them out. The beds should be in a dry position, but not exposed to the sun, and the plants dislike stagnant water, especially in winter. I generally place about two or three inches of good loam on the surface of the beds before planting out; each plant ought to be divided into single crowns, and they should be planted 9-in. apart, pressing the soil rather firmly about the stem.

Carnations and Picotees.—Some remarks were made last week about the value of the Carnation and Picotee as a town flower, and also respecting the small expense that would be incurred in furnishing beds with them; and an instance occurs to me where I saw a very large space of ground devoted to seedlings. They were planted near one of our largest manufacturing towns, and in a position where the atmosphere was charged with smoke and deleterious substances of a worse character; nevertheless there they were in the shape of thousands of plants, nearly all of which have produced handfuls of beautifully marked flowers, and the seeds from which they were raised were such as can be purchased in any seed shop. The beds contained about equal quantities of double, semi-double, and single flowers, but a single Carnation is by some considered more beautiful than one too double, the last being merely a mass of small petals, which cannot be restrained from splitting the calyx. Show varieties will now require considerable attention; some of the very best have a tendency to show split calyces, but this must be prevented by slitting the calyx down a little on the opposite side, and tying it round with a strip of bast. When the flowers open they must be protected from sun and rain; the best plan is to remove them to a position under glass.

Hollyhocks.—These are growing strongly this year; the main stem must be made secure to its support, for if not made rather firm, it oscillates when acted on by the wind, and the flowers get spoiled in the bud. Still continue to put in cuttings as previously recommended. Administering manure water is of little use, but the plants

can be much strengthened in a rainy season like the present by placing some manure round the roots. There seems some hope that the fungus, which has probably utterly eliminated many fine Hollyhocks, is at length disappearing, either from the effects of climatic influences, or because there are few plants left for it to destroy.

Gladioli.—These fine autumn-blooming plants are difficult subjects with which to deal. At one time we grew several thousands of them annually, but ultimately losses among them were so grievous that they have been almost given up. We have a few this year, but they make but little growth, and do not as yet show their flower spikes. Our wet autumns have been very much against them; they have almost invariably to be lifted while their leaves are quite green. It is much better to save seeds from carefully crossed flowers than to purchase bulbs annually; the latter are expensive, and the losses heavy, whilst from a few pods of seeds hundreds of fine showy varieties can be raised. The same cultural directions as those given a fortnight ago are still applicable. The system of leaving the bulbs in the ground all the winter I have not tried, but cannot think it would answer well unless some protection could be contrived to throw the wet off them, otherwise delicate sorts would be sure to die off.

Phloxes in Pots.—Like every other class of plants these are late this year, but they are sufficiently strong, and will gladden us with their beauty and perfume in September instead of August. The plants should be supported by means of stoutish sticks, and it may be necessary to plunge the pots in Cocoa-nut fibre refuse, or some similar material, to prevent their being overthrown by the wind. They must be attended to with regard to watering, and they will be benefited by liberal supplies of manure water up to the time when the flowers open. All such subjects out-of-doors require the same attention. The best time at which to propagate Phloxes is early in spring, but there are side-growths to be obtained now, which may be inserted either in a shady border or in small pots.

Pentstemons.—These are just coming into bloom, and the growing shoots must be carefully fastened to sticks. Pentstemons have a good effect in mixed borders and also in beds. Cuttings of them may be put in now if the object be to attain a large stock of plants, but the best time is September or early in October.

Delphiniums.—These are now in full beauty, and well repay the cultivator for any care which he may have taken with them. Nothing now is required except to see that the flowers are not injured by the wind.—J. DOUGLAS.

Conservatory.

There are many stove plants which, when treated through the spring and summer so as to induce robust growth, will bear placing for some weeks during the warmest part of the season in ordinary conservatories; this is especially the case with Ixoras, Clerodendrons, and Bougainvilleas, but where these plants are subjected to too much shade and moisture and grown in dark houses, or too far away from the glass, they will not bear to be so employed, and, consequently, much of the usefulness of which they are capable is lost. But before submitting them to the lower temperature which they necessarily receive in a conservatory, the house in which they are grown should be given more air than usual for a fortnight or so previously, and before taking them out into their cooler quarters they should be allowed to get as dry at the roots as they will bear without the flowers flagging, and the structure into which they are moved must also be kept a little closer for a few days after their admission, and during the time such plants are allowed to remain in it the air given should be so admitted as not to come in direct contact with them. The latter portion of the present month up to a similar time in August is the period when these plants will not only bear keeping cooler but when they are most useful. It will be understood that these and other stove plants of a similar character can only be used as indicated when we get seasonably warm weather, and should there be a continuance of the low temperature that has so far marked the present summer, it would be a mistake to so subject them. Many handsome-leaved stove plants such as Dracenas, Aralias, Oreopanax, Cupanias, Caladiums, and fine-leaved Begonias, can also be employed for conservatory decoration; and owing to the distinct character of the colouring of their foliage, they will in some measure compensate for the paucity of flowers at this season. Where Tree Ferns are grown in the way which I have from time to time recommended, *viz.*, in a drier atmosphere with more air and a lower temperature than that to which they are usually submitted—in fact, treated as ordinary greenhouse plants, with an absence of the daily stem syringing often resorted to to induce the production of stem roots, which are perfectly useless so far as the health and strength of the plants are concerned—the advantage of this management will now be obvious owing to the much stouter and harder condition of the fronds, enabling them to be used in conservatories, greenhouses, corridors, or, for a few days at a time, in entrance halls provided no gas is employed, without

any injury whatever. Another important matter in connection with the cultivation of these Tree Ferns which it is necessary to frequently point out, is the error fallen into of growing them in large pots or tubs, than which no greater mistake can be committed; when their roots are very much more confined than those of the generality of other plants, by the use of manure water during the growing season they will produce heads sufficiently large for all purposes. Another advantage is that they are much easier to move about, look far better, and can be used in many places in which large unwieldy pots and tubs would make their presence objectionable or impossible. A good syringing overhead two or three times a week, getting well to both the upper and under parts of the leaves, with a view to keep down thrips and to clean the upper surface from dust, will be of benefit to them.

Greenhouse.

Hard-wooded Plants.—In peculiar seasons like this, the necessity for adapting the treatment given to plants in accordance with their altered conditions is obvious. All the more generally useful hard-wooded subjects, such as Acacias, Cytisuses, Epaerises, Polygalas, Boronias, Chorozemas, Correas, Clanthuses, and others, whether of the more ordinarily serviceable small decorative size or larger, have been this spring quite a month later in flowering than usual, a circumstance which has made their growth proportionately later, and unless steps are immediately taken to make up for their backward condition, either the amount of growth made capable of flowering next year, or its insufficient ripening will to a certainty very much diminish the blooming capabilities of the plants during the following season. An opinion often prevalent is that plenty of air during the summer season and fair treatment other ways are all that plants of this description require, but it is well not to lose sight of the fact that all such plants come from countries possessing a higher temperature than that of ours, and also longer summers, and in order to induce the full complement of growth being made, I should recommend that for the next three weeks the plants be kept a little closer than usual by closing the houses and pits earlier in which they are grown, elevating the plants so as to secure every available ray of light, which will compensate for a diminished admission of air. Treatment of this kind will enable the plants to produce the requisite amount of wood, after which they can be placed out-of-doors from the middle of August to the second or third week in September, time quite sufficient to effect maturation, a process which in the open air does not take near so long in the case of the majority of plants as is frequently supposed. So far as late-flowering Epaerises are concerned, after blooming they will bear keeping in a close atmosphere and syringing overhead in the afternoons, just in the way in which Azaleas like to be treated; a very short time out-of-doors will suffice to ensure their blooming.

Azaleas.—These, excepting those forced earliest, are, through the absence of solar heat, more than usually late; they should, therefore, be kept a little warmer than ordinary, shutting up by two or three o'clock in the afternoon in the southern parts of the kingdom. This will secure sufficient growth, even in the case of the latest-flowered plants. In the northern districts a little fire-heat will be necessary. The half starvation system, of growing Azaleas by turning them out-of-doors in the summer season before their growth is nearly completed, no doubt admits of their blooming to a certain extent, but such treatment invariably induces small indifferent flowers and puny growth, whereby, especially when cut, the wood that can be taken off attached to the flowers is so small as to much diminish their usefulness, and they always get into a more or less hard stunted condition. This, as a matter of course, does not apply to plants managed in such a way as to have them in bloom through the winter or early spring, and which consequently make growth proportionately early; but even in their case they are much better kept entirely under glass.

Camellias.—Such of these as flowered early will require to be treated in accordance with the time when they are again wanted in bloom; there is no difficulty in gaining a month or six weeks each year in the earlier opening of the flowers where this is deemed necessary, until, if desired, the earliest will begin to open by the middle or end of July. In most cases, however, their flowering so early would be rather a disadvantage than a gain; but where the earliest have not bloomed until, say the first month in the year, they may be had six weeks sooner than this in the coming autumn by simply letting them remain in warmth sufficiently long after the buds are set. This treatment keeps them on growing to an extent that admits of their full development much earlier than would otherwise be the case, an effect that heat in the way of forcing will not have upon them when they have once been induced to a comparative state of rest after the buds are formed by placing them in a perfectly cool house, or in the open air. The latter treatment I should by no means recommend, except as a matter of necessity, where there are no means of accommodating them in a house where they will be but

little under the influence of the sun, or under a temporary covering of loose lights, or a canvas blind that can be put on or off when sun or wet requires it. Camellias out-of-doors when the plants are strong and healthy, and comparatively large for the pots or tubs which the roots occupy, need to be very carefully treated during the next two months; care must be taken to see that they do not want for water, a condition from which they are much more likely to suffer than in cases in which there is more proportionate root-space.

Heaths.—All, except the latest spring-flowering sorts, should by this time have made sufficient growth to enable them to be set out-of-doors, but with the hardest-wooded kinds care should be taken not to fully expose them to the sun for the first few days, or their leaves often become so browned as to be permanently injured. The dark bronzy-green tint which these plants get from open-air exposure, is, when present to a moderate extent, indicative of health, but not when carried too far, as is evident by the foliage when it assumes this colour sometimes dying off prematurely. A matter of great importance with these, and all other hard-wooded plants set out of doors, is to protect the pots on the side exposed to the sun, as a single bright day will frequently have the effect of reducing the roots, which in healthy specimens usually lie closely packed against the insides of the pots, to a condition which for a time stops their further extension. Young plants placed close together to some extent shield each other, and, moreover, the soil contained in their pots is not usually so full of roots as in the case of larger examples, consequently they are less likely to suffer in this way.

Greenhouse Campanulas.—The white and blue pyramidal varieties of these, usually treated as biennials, need special attention, as they in common with most other plants are this year late and small; nothing must, therefore, be left undone to encourage them to acquire size and strength before autumn, for on this depends the display which they will make next summer. Where the seeds were sown somewhat late, many may not get strong enough to flower at all next year, but, fairly treated, they will make fine blooming plants the year following—erect columns of flowers 10 ft. or 11 ft. in height, if kept to a single stem and grown in pots sufficiently large. The old drooping *C. fragilis*, now seldom met with, is one of the most beautiful long-blooming plants which we have for standing on brackets, the edges of shelves, or in similar positions, where its profusely-flowered pendent shoots can be seen to the best advantage, and its colour, pale blue, from its comparative scarcity in greenhouse subjects, makes it still further desirable. It strikes freely from cuttings put in any time during the spring and summer in ordinary soil; small pots 7 in. or 8 in. in diameter are sufficient for even large specimens. The plants will last for a number of years. In addition to their usefulness for greenhouse decoration, they are amongst the best plants that can be used for rooms or windows.

Lilies in Pots.—These will now require attention; the necessary supports, consisting of a single stick to each stem, should at once be put to them. Where there are several bulbs in a pot it is necessary to be careful as to how the sticks are inserted, otherwise the bulbs will get injured. Where the plants are strong, and the pots comparatively small for the number of bulbs which they contain, the roots will by this time have permeated every particle of the material, and even although it contains plenty of manure, it quickly becomes impoverished so as to insufficiently support the plants. This is particularly the case where these beautiful subjects have been treated as they ought to be in one of their most important requirements, and that is not to overpot them. It is questionable if liquid stimulants are of much use in the early stages of the season's growth; but when the plants have attained the condition above indicated, liquid manure is of the greatest possible benefit in enabling them to retain their lower leaves in a green healthy state until the flowering is over, which not only is of importance so far as appearance goes, but is equally worth consideration on account of its imparting strength to the bulbs for the time to come, for I have invariably noticed that the bulbs of Lilies which retain their leaves in the healthiest state the longest, increase the most in size, and produce a proportionately greater amount of flower. This particularly applies to the varieties of *L. speciosum*. Another matter is to keep them scrupulously clear from insects, as there are few plants that sooner suffer from neglect in this matter. *L. eximium*, the earliest bloomed plants of *L. auratum*, and others that have done flowering, so far as their future well-being is concerned, require to be just as well treated in the matter of attention as to water, so long as their leaves keep green, as they did previous to blooming.

T. BAINES.

Hardy Fruit.

The crisis as regards fruit prospects has now been reached, and it is with regret that I have to express my conviction that 1879 will have to be recorded as a year of scarcity, notwithstanding the bright prospects which existed a few weeks ago. Still it rains; and Straw-

berries, though full crops, must suffer; indeed, they have already suffered, many having rotted off in a young state. They have to be netted from birds, which are just as troublesome as in a season of drought; shooting one occasionally frightens many away for some time, particularly if the dead bird be exposed as a scarecrow. Red and Black Currants and Cherries are also ripening, and require protection with netting, or, what is better, gathering them. Any that are to be netted up for dessert purposes in the autumn will require more than the usual amount of attention in order to prevent mildew and decay, which, owing to the excessive moisture both in the ground and in the atmosphere, are sure to be prevalent. As a safeguard the netting should be removed for an hour or two whenever the weather is fine and the winds drying, and provision should be made for this by so fixing it at first that it may be expeditiously removed and replaced as desired. Apples, Pears, and Plums are making most luxuriant but by no means fruitful growth, and repression, by cutting back all the most watery and strongest shoots, must still receive attention; but remove a portion only at one operation, so as to avoid giving a severe check to the trees, and allow an interval of a week ere another portion is removed. A good rule is to take all the strongest shoots first, as these are sure to require a second stopping, whilst for the weaker growers once will suffice. I fear there is not much occasion to recommend thinning the fruit, though if any are so fortunate as to need to do this, it ought to be done forthwith. We have had to thin all trees on walls and a few standards. The following kinds of Pears are fruiting well, viz., Beurré de Capiaumont, Passe Colmar, Marie Louise, Jargonelle, Easter Beurré, Seckle, Winter Nelis, Glou Moreau, Pimaston Duchess, William's Bon Chrétien, Beurré Hardy, and Thompson's. Peaches and Nectarines that have been badly affected with blight or blister, if now clean—as they will be if remedial measures have been applied—will be making fresh growth, which ought to be left intact till there is danger of overloading, when the removal of surplus shoots may take place, and the permanent ones be tied or nailed in, in order to forward maturation, for the season is so advanced, that even with the brightest weather from the present time, they will require all the assistance that can be given them in order to attain this object. The final thinning of the fruit should now be done; ours—a full crop—were thinned three weeks ago; for obviously there must be less danger of the fruit failing to pass the critical ordeal of stoning when thinned early. Early Apricots are in their last swelling stage preparatory to ripening; the fruit should therefore have full exposure to any little sunshine there may be, for even in the best of weather it is difficult to get Apricots to ripen throughout, the side next the wall being often hard and green whilst the front is dead ripe. Spur in the shoots to within a couple or three leaves of the old wood, and tie in all new shoots required to furnish the wall or that are required to take the place of old spurs at the winter pruning; for the present these may be tied over the old spurs, the shoots produced by the latter being kept rubbed off. The leaf-rolling caterpillar has made its appearance; hand-picking is the only effectual mode of getting rid of it, and if this is resorted to as soon as the pest is first perceived it will not be troublesome. W. W.

Parks and Open Spaces.

Gravel and Tar-paved Walks.—Walks, whether formed of gravel or tar-paving, require some attention at this period of the year, as it is extremely uncomfortable to walk upon loose gravel or upon tar-paving which, as is too often the case, has large stones showing through the surface. To remedy this evil in the case of gravel walks, especially those which are formed of gravel of good binding quality, in addition to constant rolling in showery weather, the surface should be occasionally strewn over with sea sand or finely broken cockle shells. If this is done once a week during the summer months, it will be found to be an immense improvement and greatly assist in keeping down weeds. The cost is very trifling, as if done as often as suggested only a light sprinkling will be necessary. During very dry weather, and when the wind is high, the walks should be lightly watered to prevent dust and the fine materials placed on the surface from being blown away.

In the case of tar-paved walks the method of procedure should be totally different; there should never be any loose materials put upon the surface. It is quite a mistake to sprinkle sand or shells upon such walks, for the following reasons: it always lies loose; watering is destructive to the paving; in case of showers the walks do not dry so quickly as when perfectly clean; and the materials are easily blown upon the adjacent Grass or along the edges of the walks, to be carried into gullies and drains during the first heavy shower. The best method in my opinion to deal with walks of this description, when they have become deteriorated from the effects of wear or other causes, is to paint them over with gas tar and cover the whole surface over thickly with very fine sea-shells or sand composed of fine sharp grit; the two may be mixed in equal proportions also if preferred. When this has become thoroughly set the walks

should be kept perfectly clean. This work is inexpensive, and really makes an excellent surface upon which to walk. I am very much surprised that tar-paved walks are not more generally made than they are, and that those who adopt them should be so careless respecting their maintenance. It must be borne in mind that there is no kind of paving which does not require some expenditure to keep it in good order, and a great saving is effected by so doing. In this respect I maintain that well-made tar-paved walks are far in advance of those made of gravel, *i.e.*, the cost of maintenance is considerably less, no rolling being required and no weeding. How often these walks should be painted over very much depends upon the materials of which they are composed. I may, however, with safety say once in three years. They should never be made in damp places nor under the shade of trees and shrubs, and in every case the drainage must be rapid and perfect. Although some years have elapsed since the introduction of this paving, there seems still to be a want of knowledge or care in its manufacture, resulting frequently in failure. Thus, in some instances, too much tar has been used, rendering it soft in hot weather; in others, not sufficient to ensure a well-bound surface. Sometimes the tar is of bad quality, the stones not thoroughly free from dirt, improperly burnt, or the mixing indifferently done; these are evils easily avoidable. In hot weather, upon the slightest appearance of tar on the surface, it should be covered with fine materials as recommended after painting. In cases where, from an insufficiency of tar, the paving crumbles, it should be dressed over without delay. Where expense is no object, asphalt would make the most durable walks, the cost of maintenance being reduced to a minimum. Wood paving might also be used with advantage in many positions; this is fairly durable, and both are noiseless.

Fences.—Good fences are of great importance in public parks and open spaces; they should not, therefore, at this period of the year be neglected. Fences, whether of iron or wood, may, with great advantage from a preservative point of view, be painted, tarred, or varnished, Stockholm tar being preferable to gas tar for wood fences, tree guards, &c.; it is, however, much more expensive. Generally speaking, tar should only be used in quite out-of-the-way places; in the more conspicuous positions paint or varnish must be the materials employed, the most suitable colours being maroon, chocolate, and green, the two first for fences and gates, the latter for trellises and such like structures. Iron fences may very properly have a coat of black varnish, a most excellent and inexpensive material easily applied by an ordinary workman. This is particularly adapted for the standards of wire fencing, continuous rod and bar fencing, iron hurdles, &c. Galvanised fencing is not generally supposed to become oxydised, but in London, whether from the chemical influence of the atmosphere or other causes, it does become injured after a few years, more particularly on that side which is most under the influence of the sun's rays; therefore it is advisable to give it a coat of varnish after a few years' wear. This work not only preserves those materials to which paint, &c., is applied, but also adds its quota to the appearance of a well-managed park or open space.

General Work.—Branches of evergreens may now be pruned out so as to give a natural and easy outline to shrubberies. Edgings of Ivy, Euonymus, Box, &c., which have made young growth freely should be carefully looked over with a view to filling up any bare places, taking out unsightly leaves and useless shoots. Box may be clipped in the ordinary way. Hedges which are usually maintained in a symmetrical condition, as Privet, Holly, Laurel, Thuja, Quick, &c., must now have their summer clipping, filling up gaps with branches by laying them across the openings. The only necessary attention to give to trees in streets, avenues, or plantations, is to ensure their being secured from danger in case we should experience boisterous weather. Lawns must be frequently mown and swept, using the roller assiduously in damp weather. Daisies, Dandelions, and other objectionable weeds in Grass must be eradicated on every favourable opportunity, taking care to do the least possible injury to the turf. I have found a slight sprinkling of salt beneficial to Grass at this season; it should be applied in wet weather. Those who grow common spring flowers as Daisies, Pansies, Arabis, Aubrietias, Forget-me-nots, &c., may now sow seeds in cold frames, pricking them out when ready; they will thus make good strong plants by the time the bedding plants have played their part. The above may also be propagated by means of cuttings or root division; indeed, seeds of most perennials may now be sown in nursery beds, and a few annuals in borders for late flowering. A mulching of well rotted manure given to beds of Asters, Stocks, Zinnias, Helichrysums, &c., will materially assist in developing their flowers and deepening their colour. Lakes in which the water is stagnant are often covered with confervæ, &c., at this period of the year, which should be removed by means of mowing, raking, &c. As this objectionable vegetation, however, generally arises from germs deposited in the mud at the bottom of the lake, it is often ad-

visible to thoroughly clean out those which are in a very bad state. Lakes should if possible always be formed in those positions best calculated to ensure an abundant supply of fresh water, either from running streams or springs. [C. DENNIS.]

ROSES.

Striking Cuttings and Budding.—Both stocks and buds are this season very backward, and in the north of the kingdom the middle of the month will have been reached before there is a chance of doing much budding; no time should therefore be lost now as regards this matter. But except in the case of scarce new varieties which can be increased faster in this way than by propagating them on their own roots, in private places, for which these remarks are intended, Roses are very much better on their own roots, and if cuttings are put in in sufficient quantities at the different seasons of the year, when they will strike, the stock of Roses, if wanted in abundance, may in a few years be all had in this way. The great numbers of fine Roses that now exist, of all shades and colours, with vigorous strong constitutions, are such as to make cultivating weakly flowers a mistake, however beautiful the individual flowers may be. It is easy to understand that those who grow Roses for exhibition should cultivate some of the weak-constituted sorts, which, when grown in quantities of each variety, often furnish a few extra fine blooms; but no greater error can be committed by those who grow Roses for ordinary purposes than cultivating such weakly flowers at all. One of the most successful methods of striking Roses that I have ever found is when the first flowers of the season are over, and when the shoots which have borne them have pushed the second growth, to take them off when they have reached a half-ripened condition and insert half-a-dozen cuttings together in 5-in. or 6-in. pots in sandy soil. Place them in a cold frame quite moist; shade and keep the frame so close that the air given will not cause them to flag, and in three weeks' time the base of the cuttings will be callused over, when, if the pots are then plunged in a slight hotbed and treated like other cuttings, they will root directly and make useful little plants before the autumn, whereas if put in heat before they are callused over, three-fourths of them will damp off.

Mildew on Roses.—The plentiful supply of moisture we have had through the summer has in a great measure prevented the prevalence of mildew, which often makes its appearance in private gardens, and is generally much more troublesome there than in the more open spaces in which Roses are grown in nurseries. Apart from the unsightly appearance which plants so affected have, it does them much harm, and completely spoils the autumn bloom which ought to be forthcoming. Therefore, as soon as ever the parasite is seen, means should at once be taken to destroy it; sulphur in some form, either dusted on the leaves, or in water, will be found the best remedy.

Pot Roses.—Plants intended for producing the first flowers under glass after the latest Tea varieties are over-out-of-doors, should be well attended to, removing all the buds that are formed as they appear. Keep the foliage clear from red spider, aphides, and mildew; syringing overhead with weak Gishurst compound will be an effectual remedy for each of the above pests. The greater portion of the stock grown in pots used for forcing will with most growers be now out-of-doors for a rest, and it is here, and at this time of the year, when they often suffer, especially from the attacks of mildew, to which the leaves that have been formed under glass are exceptionally liable. It spreads most rapidly, and the only way in which it can be coped with is to apply the sulphur remedy immediately a trace of it is discovered, for if the plants get much affected they will be so far weakened as to be unable to push strong flowering growth when placed in heat. Should any of the young advancing plants need more root-room, larger pots should be given them without delay so that the soil may get filled with roots before winter sets in. Roses planted out in houses also need constant attention as regards giving them manure water when necessary to stimulate stout growth, and regularly using the garden engine or syringe to keep them clear from insects. T. BAINES.

Roses at Stapleford.—Mr. Bennett's Roses are very interesting, and look as if they would prove very valuable, but few good blooms were open when I saw them. He has carefully fertilised many of them with pollen from other good sorts, and has kept the names of both parents, and the characteristics of both are often seen in the offspring. Most of the female parents are Tea Roses, as they seed more freely. President is the dam of many of his best seedlings. He has propagated only nine to send out, but among the

stock we saw four or five others very distinct and apparently remarkably strong. His Hybrids have in many cases the glossy foliage and glaucous stems of Tea Roses, with the sturdy growth of Hybrid Perpetuals; some, on the other hand, have the slender habit of Teas with strong coloured flowers. They seem to be wonderful bloomers, never sending up a shoot without a bud on the top. His little plants of Duke of Connaught, a fine crimson, which he is going to send out, are in 2½-in. pots, and all crowded together in a house, but they all keep their leaves, and many of them have two blooms, each nearly as large as the pot. Our own Roses are just coming out, and are very good in colour; but there are very few other flowers. Those who are depending on Pelargoniums for flowers will be taken in this year.—A. P.

Roses at the Ascot Nurseries.—The increased demand for Roses on their own roots, especially the Tea and Noisette varieties, is everywhere apparent, but in none so much so as in the establishments where these are grown largely for sale. We recently saw a couple of houses at the Ascot Nurseries filled with 4000 plants of Maréchal Niel and Gloire de Dijon grafted at the commencement of the year; they were in 6-in. pots, with from two to four shoots each about 3 ft. high, and were just about to be moved into 8-in. ones, and potted down so as to get the point of union between plant and graft below the soil, which will at once induce the formation of roots above the juncture, when virtually they will be on their own roots. All the leading Tea varieties are here treated similarly.—P. G.

Rose Houses.—Houses built specially for the culture of climbing Roses will soon become common in all moderate-sized gardens. They specially commend themselves to amateurs, inasmuch as when once the house is erected and planted little else is required. Heating is not a necessity, and may be employed or not as may be found desirable. Low span-roofed houses, with roofs coming down to within 12 in. of the ground, and with plenty of ventilation on either side, and a sunk path in the middle of the house, answer well. The plants may in some cases be planted outside and some inside, and the sorts should be chiefly Teas of several colours, specially those that produce pretty button-hole flowers. They should be trained up wires just as Vines are. I shall this spring and summer cut, out of a span house not yet half covered, about fifty dozen of Roses, chiefly in a half-expanded condition.—A. D.

Rabbit-proof Plants.—“Salmoniceps” (p. 452) is mistaken in supposing that Lilies enjoy any immunity from the attacks of rabbits. Three or four weeks ago I put out some plants of *Lilium auratum* from 1 ft. to 2 ft. high on a newly turned-up piece of meadow land, and, to my annoyance, they were immediately attacked by rabbits, and all but five or six eaten nearly down to the ground. The plants that were left owed their escape to their being from 1½ ft. to 2 ft. high; but, at the time I write, these have been reduced to two, and they are all that remain of about twenty-five plants which I planted out. I sowed seeds of the Canary Flower (*Tropeolum peregrinum*), which I intended to grow for seed, and these have also been attacked by these pests. I am quite at a loss for a remedy. Can any of your readers suggest one?—J. M.

Market Garden Farms.—The following are the prize winners in the “Market Garden Farm” competition, held in connection with the International Agricultural Exhibition at Kilburn. Section II. Class 3.—Market Garden, exceeding 10 and not exceeding 50 acres. Mr. William John Gay, Barking, first prize; Mr. William Gay, Corbetstye, Romford, second Prize. Section II. Class 4.—Market Gardens above 50 acres. Mr. John Lancaster, Vine House, Canning Town, first prize; Mr. Thomas Patch, Barking, second Prize. Section III. Class 5.—“Market Garden Farms,” within 50 miles from the Mansion House.—Mr. H. Swan, manager to trustees of late J. Circuit, Rainham, first prize; Mr. William Walter Glenny, Cecil House, Barking, second prize.

Central Fruit and Vegetable Market.—The Corporation of London, at their last meeting, approved the City Architect's plans for the erection of the London Central Fruit and Vegetable Market, on land adjoining the Central Meat and Poultry Markets at Smithfield, at an estimated cost of £115,000. The market will have a frontage on four streets or roads, viz., Charterhouse Street, Western Roadway, New Southern Roadway, and Farringdon Road. There will be three principal entrances, on the east, north, and south. The plans show an area of nearly 44,000 ft. devoted to wholesale market purposes, surrounded by forty-one shops, fronting the several streets, which can be used for retail and other purposes, and these occupy an area of some 16,800 ft. The general appearance of the building externally will be as similar in character to the other markets as the less expensive nature of the works will allow. The cost of the superstructure is estimated at £115,000, but the land and approaches will cost in addition £175,937.

THE INDOOR GARDEN.

PORTUGUESE CALADIUMS.

It may be asked why these plants are called Portuguese Caladiums, seeing that the type, of which they are the varieties, is a native of Para; it is, however, fully justified by the fact of these varieties having first been produced in Portugal, a country which possesses an exceptionally favourable climate for the purpose. M. Bleu, a well-known amateur horticulturist, has succeeded in bringing the eminently ornamental plants forming this group to the highest state of perfection, the specimens shown by him at the various French horticultural exhibitions always attracting crowds of admirers. Besides their graceful form, the nature and texture of the leaves and the exquisite harmony of their colours are objects of admiration to everybody. To describe these plants with justice would require the use of a whole regiment of superlatives. There is, however, one reproach to be made against M. Bleu's pets. In spite of all their other perfections, it must be allowed that their general habit is somewhat uniform, and, according to a well-known French proverb, "weariness is the child of sameness." In nearly all the numerous

Portuguese Caladium.

varieties which he has grown there is a great similarity of form in the leaves, irrespective of their dimensions, they being generally hastate, heart-shaped, more or less scalloped, and peltate. Such, generally speaking, was the state of things up to 1877, when a new type of Caladium appeared at the Oporto Horticultural Exhibition, which included a whole series of new varieties completely differing in their form from anything that had been seen before. Instead of a heart-shaped or hastate leaf, it had a blade more or less spread out without appendages, and which appeared to be produced in some sort by the elongation and widening of the leaf-stalk. The plants of which we are speaking are typified above, and are the result of artificial fecundation as carried out by Mr. Jacob Weiss, chief gardener to the Duke of Pamela. They were shown at the Oporto Exhibition of 1877, and carried off the gold medal. Some of the more remarkable of these plants were afterwards sold in London to Mr. William Bull for £50, a sum which Mr. Weiss generously and disinterestedly devoted to charitable purposes.

If these new specimens cannot boast of being comparable with the magnificent varieties obtained by M. Bleu, they certainly differ from them entirely in their form. The leaves of several of the specimens are almost linear in shape, some of them being from 6 in. to 12 in. in length and even longer. Others, again, are more elliptical in their

character, but the whole of them have the petioles running into the leaf, as it were. In others, again, the edge of the leaf is distinctly scalloped, and although less brilliant in colour than M. Bleu's varieties, many of them are variously tinted, and approach in hue to the intense colours of the Parisian Caladiums, thus showing that progress has been made as far as the change of form goes, which may be considered as a decided step in advance. An attentive examination of these new forms seems to indicate that the parents of these Portuguese Caladiums are *C. Barilleti* and a Brazilian species with leaves attenuated at the base, probably *C. Wendlandi*, but this is merely a supposition. E. A. CARRIÈRE.

COMBRETUM PURPUREUM.

THIS is unquestionably one of the most showy and useful plants that can be grown for training up under rafters, as it may be readily kept to a limited space, and is very floriferous. Except in a few instances, climbers confined to pots are not seen in good condition, from the simple fact that they require a more extended root-run; a check in this way by too great a restriction is a mistake; for, although it may make them bloom a little more freely, they invariably assume a very starved appearance—so much so as to greatly detract from their beauty. The *Bougainvillea*, however, is an exception, as that cannot well be too cramped, the tendency of this plant being to run riot if it has the least liberty. With the *Combretum* the case is different, and the best way of managing this is to partition off a corner of the floor of the house where it can have proper drainage, which may be afforded by a quantity of broken bricks; and, to ensure the interstices between these being kept open and clear, it is a good plan when forming the bed to lay some large sods of peat over them before the final filling up takes place. These settle gradually on the top, where they become embedded and leave all hollow below, in which state a border, when so managed, will last for years, and always keep sweet and healthy for the roots to feed on. Although the *Combretum* will grow in almost any soil, it prefers that which contains a good deal of vegetable matter, and where peat can be easily obtained, it is always advisable to use that principally; but in case of scarcity a good substitute may be found in a mixture of loam and leaf-mould, to which should be added about an eighth of its bulk of sharp sand to ensure perfect porosity. This mixture, pressed in firm, will grow the *Combretum* to perfection; but, like all climbing plants of its class, the great thing is to so train it that it may be fully exposed to solar influence, the effect of which is to consolidate and mature the shoots, for, without this, it never flowers with anything like the freedom it is capable of. The habit of the plant renders it particularly suitable for training up strained wires placed within 1 ft. or so of the glass, where, from its favourable position as regards light, it is sure to be satisfactory. A medium temperature, such as that of a cool stove, answers perfectly, and is quite enough to keep it in a state of luxuriant health. S. D.

SUMMER TREATMENT OF INDOOR PLANTS.

CONSIDERING how much cheaper the culture of various plants, which are largely used in greenhouses and conservatories in winter and spring, when planted out during their period of growth is, in comparison with pot culture, it is strange that this method does not find more favour. Our forefathers acknowledged its merits, but their methods of treatment were of too rough and ready a character. New Holland and Cape of Good Hope species, *Azaleas* and *Camellias*, were by them, soon after the bloom was over, taken out of the pots or tubs in which they grew and put into the mixed herbaceous borders, or into the foremost ranks in the shrubberies. The labour of watering and cleaning them from insect pests was thus very much lessened, but it is questionable if the subjects so treated would now-a-days meet with the approval of a good plant grower; for owing to the deficiency in the average of garden soils of those ingredients necessary to proper development of foliage and flower, they would not attain to the same beauty as when otherwise grown. Old practitioners, I think, failed in not making beds or borders of the mixtures of soils that the various classes of plants required. When such borders are made well-drained, where needed, and of materials of not too fine a texture, many plants do wonderfully well in them and reward the cultivator with fine foliage, healthy, green, and free from insects, and if the wood is fully ripened, with abundance of bloom; to ensure the latter, sunny positions only should be selected for the beds, which should, if possible, run from north to south. Indian *Azaleas* are very apt, after blooming profusely for two or three years, to make weak growth, and very small wiry leaves; when that happens they should be put out into the border as soon after flowering as the weather permits; if well rooted, the outside of the ball should

ne loosened with a pointed stick, and in one season their renovation will be complete. It will thus be understood that the plants are to make their growth out of doors. Herbaceous heaths, of course, require a peat-bed—Abelias, Boronias, Acacias, Hakas, Cytisus, Citruses, Hoveas, Correas, especially alba for the making of stocks for grafting. All these should be planted out, as should also Cantua dependens, Plumbago capensis, Agnostus sinuatus, Cyclamen of all varieties, Rhynchospermum jasminoides, Bouvardias, Pineleas, Aloes, Pittosporum undulatum, Banksias, which are required to be grown large, and Eucalypti. These are but a few of the genera which I have so treated, and which have always rewarded me with satisfactory results.

Stopping and pinching, when thought necessary, and in the case of such subjects as will bear it, can be done just as well as in pots. But this oft reiterated system of constant pinching and pruning back leads certainly to the attainment of a greater quantity of smaller blooms, but at the sacrifice of the longevity of the plant so treated. Graceful tassels, bunches and garlands of bloom partly hidden amongst healthy foliage, are objects of greater beauty than the round-headed and otherwise trained monstrosities too often seen. I may mention in conclusion that the Camellia does very well planted out, but in no case should it be put out if it has already made its growth under glass, or when an early bloom is looked for; C. simplex planted in the form of cuttings in a frame for two summers, and protected slightly from frost during winter, makes strong stocks for grafting or inarching. Cinerarias make better plants for winter and spring use if planted out in a frame; the leaf is finer, and insect pests are less troublesome. The beginning or middle of September is a suitable time to lift and repot all subjects named above that are not hardy, and for a few weeks after they are housed they must be subjected to a close but healthy temperature.

Moravia.

SYLVESTRIS.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Amaryllises as Decorative Plants.—Few plants are more deserving of extensive culture than the many beautiful varieties of Amaryllis that have of late years been brought prominently into notice. They are so very distinct and majestic in appearance that for either drawing-room or conservatory decoration they are unsurpassed, and as regards cultivation they are about as easy a class of plants as can well be grown. In good loam, rotten manure and sand, potted firmly in not over large pots, they will last for years. The chief point requiring attention is to perfectly ripen off the foliage before they are stored away.—J. GROOM.

Heaths at the Ascot Nurseries.—Amongst the well-known kinds of winter-flowering Heaths the two varieties Hyemalis and Wilmoreana still keep much more in demand than others; their stout, free-growing habit and equally free disposition to bloom account for this. The same remark applies to the summer-flowering, hard-wooded sorts, which, we understand, from the quantity sold, are again being much more used for decorative purposes than they have been for some years back; the yellow-flowered E. Cavendishi, and the pink and red Venticosas, such as V. coccinea minor, V. grandiflora, and V. tinctoria rubra, have the largest sale. The stock of Heaths in the Ascot Nursery consists of some 35,000.—P. G.

Planting out Camellias.—These are slow-growing plants in their first stages, but much may be done to save time by planting them out for a couple of years. At the Ascot Nurseries the centre bed of a large, low, span-roofed house has been planted with Camellias. They were turned out of 8-in. pots early last year well furnished selected plants; they took freely to the new soil and made strong growth, any over-luxuriant shoots being shortened; this season they have made even greater progress; in fact have done as much in the two years as would have been possible in four under pot culture. Every other plant will now, as soon as its buds show a disposition to form, be taken up and potted, and the others will be allowed to grow and flower until they are again short of room, when more of them will be similarly potted.—P. G.

Anætochili at Home.—Mr. W. B. Freeman, well known as a plant collector in India, writes, regarding the natural habitats of Anætochili, that he has found them at an elevation of from 3000 ft. to 4000 ft. above the sea-level, and most frequently in ravines near mountain streams. Though the temperature must fall much below freezing in winter, the plants are never exposed to the direct influence of frost, being sheltered by trees. The maximum temperature probably never exceeds 70° Fahr., and this can only be for an hour or so in the day. They grow freely in a temperature of 65°, and rot off very quickly if any decayed vegetable matter or mildew is allowed to accumulate about the stem. They should never be allowed to dry up, though free drainage is undoubtedly essential. The soil in which

they are found growing is a combination of peat and vegetable mould.—*Florist.*

Odontoglossum vexillarium.—This, when strong, bears five, six, or seven flowers to a spike, the terminal blossoms being somewhat smaller than those at the commencement. There are generally two or more up to six or seven spikes to a strong pseudo-bulb. The colour varies from the palest to a deep rose, and it is remarkable that the depth of colour varies much in the same plant in different years. My Orchid grower thinks that the tint of rose is deepest when the flowers open in a brisk heat; but I am not clear as to this yet. It is generally supposed that this Odontoglossum requires the heat of a Mexican house, in winter at all events. I believe that a few degrees, say 5° Fahr., more heat than we give to such of its congeners as O. Alexandræ are advantageous to it; but it is very liable to thrips, which greatly disfigure its beautiful glaucous foliage, and it will certainly thrive side by side with O. Alexandræ.—TREVOR LAWRENCE, *Burford Lodge, Dorking.*

Grevillea Manglesi.—This is one of the rarest and most graceful of all greenhouse shrubs, its thin, twine-like branches drooping from 4 ft. to 5 ft., being clothed with fresh green leaves and tiny clusters of white flowers. Although so distinct and beautiful it is one of those plants which do not succeed well in our greenhouses without some special assistance in the way of propagation and after culture. Propagation is not so very difficult to effect by means of cuttings treated much as one would treat those of a Heath; but scarcely one plant in twenty so increased will survive long enough to form a specimen like that in the Dublin Royal Botanic Gardens, which is no doubt a grafted plant. Seedling plants of Grevillea robusta, trained as standards, form excellent stocks for this weeping plant, than which in its own distinct way no greenhouse shrub can possibly be more lovely or desirable.—F. W. B.

Fuchsia corymbiflora.—The inclination to prefer the new to the old in plants often leads to good old decorative subjects being either forgotten entirely or relegated to the collections of the curious rather than of the general cultivator. All who have seen the Fuchsias in the conservatories at Hatfield or at Chiswick House will know how beautiful they are in the form of climbers, and as a pillar plant Fuchsia corymbiflora is now a beautiful sight in one of the conservatories at Glasnevin. Trained erect to a height of 10 ft. or more, and its growth then allowed to arch or fall unrestrained, it is exceedingly graceful, each branchlet being weighted down by great clusters of tubular flowers, vivid crimson in colour and about 4 in. in length. Treated in this way it is a sight worth going miles to see. Although long introduced, it is by no means rare; but it is only as a large specimen that it is seen to the best advantage.—B.

Russelia juncea as a Basket Plant.—Basket culture is better adapted for showing off the graceful drooping habit of this plant than pot culture, under which the long branches must have support of some kind. Then, too, when the basket is well covered, one may occasionally steal a long trailing piece for mixing with cut flowers, for which purpose the graceful sprays are peculiarly fitted. The plants should be grown in pots the first year, or till they are strong and well established. Wire baskets are best, using plenty of Moss for lining them—as this will be necessary, not only for keeping in the soil, but to prevent the earth drying too rapidly. One or more plants may be planted in each basket as may be necessary. It is, however, always best to fill the baskets tolerably full at starting, as they are effective immediately. Until the basket is well covered, the young shoots should be pegged over the sides and the bottom; afterwards permit them to grow as they like. The Russelia is classed as a stove plant in catalogues, but when established it may be moved to the conservatory. It is easily propagated; young shoots strike freely. It also often strikes root at the points where they touch the soil or Moss.—E. HOBDAV.

Boronia megastigma.—Amongst the numerous Australian plants that we now possess for greenhouse decoration perhaps none has attracted more attention than the subject of the accompanying illustration, not on account of the colour of its blossoms, which are far from showy, but on account of the delicious aromatic perfume exhaled by them and the graceful habit of the slender branches on which they are produced. In its native habitat it grows about 2 ft. high, and has twiggy, erect branches on which, during spring and early summer, are copiously produced small bell-shaped blossoms of a maroon-purple tint outside and greenish-yellow within. It is a native of King George's Sound and neighbouring districts, whence it was originally sent to this country by Baron von Mueller. This and the Rosy Boronia (B. elatior), of which a coloured illustration was given in THE GARDEN, Vol. X., Plate XXXIX., are two of the most desirable greenhouse plants with which we are acquainted. The plant that furnished the spray from which our woodcut was prepared was growing in Messrs. Veitch & Sons' nursery, at Chelsea, who have repeatedly exhibited this Boronia at the various metropolitan shows during the past few years.

Chamædorea Hartwegi.—It is the elegant or the majestic habit of Palms, and the conspicuous character and freshness of their leaves, which distinguish them as decorative plants. Some Palms also possess floral charms, in which respect none are more beautiful than *Chamædorea Hartwegi*, which develops its branched spadices, studded with numerous orange-coloured petals, during winter and spring. The male plants are more showy than the female, but when the former have shed their bloom, the latter become ornamental by the production of fruit, which remains till the close of the autumn. The *Chamædorea* is a native of the Caraccas, an elevated region near the coast of Venezuela, 10° north latitude, consequently it thrives best in a stove or an intermediate house. Plants 2 ft. high and upwards make good flowering specimens; but in order to secure an effective display, three conditions are essential—namely, liberal supplies of water and of liquid manure during the time of active growth; exposure to air and sunlight, so far as this can be done without scorching; and, lastly, the destruction of scale and bug, which often lodge unobserved in the axils of the leaves. Standard plants will succeed for several years in a 10-in. pot, but to prevent its becoming too dry during the heat of summer, I place flats below them. The soil should consist of a good fibry loam with a little sand added, and the potting must be firmly done. Fertilisation is effected simply by placing the two sexes so that the pollen falls on the female spadix; but the operation must be performed when the stigma is well seen, and when the stamens will bear a touch with the point of a knife. Our plants have bloomed in succession since November, and those which were fertilised are swelling their fruit.—JAMES SCOTT, in *The Gardener*.

Eremurus Robustus in America.—This is one of the noblest and handsomest members of the Lily family, and is a native of Turkestan. It bloomed here last year, for the first time (so far as I know) on the American continent. I received the bulb from Max Leichtlin in the autumn of 1877, and treated it as a "cool" pot plant till the spring of 1878, when I planted it in its present place in the out-door rockery. There it grew robustly, bore a scape 6 ft. high, and was in blossom during the first fortnight in June. It also ripened a considerable quantity of seeds. Encouraged by the possession of plenty of seed, and the belief that the *Eremurus* ought to be hardy, coming as it does from the home of Tulips and several other hardy plants, I ventured to leave it out over winter, and fortunately succeeded. This spring it came up with a vastly invigorated constitution and appearance, and is now (second week in June) in the glory of full bloom. It has a large tuft of many stout, linear, radical leaves 3 ft. long by 2½ in. to 3 in. wide, and a scape 8½ ft. high, terminating in a dense raceme 3½ ft. long, containing over 400 pale pink flowers, of which from 120 to 140 are in bloom at one time. Each blossom is about 1½ in. across. It lasts in beauty more than a fortnight, and presents such a striking appearance from a distance, that people passing along the street, and who seemingly care no more about garden plants than they do about the stones on the road, hitch their teams and come in to see what sort of plant it is. *Eremurus turkestanicus* is an equally rare species from the same habitat as *E. robustus*, and growing near by it, and under the same conditions has also proved as hardy and thrifty, though by no means such a strong growing or ornamental plant. It starts earlier into growth, and is done blooming by the time *E. robustus* begins. Its blossoms are dark red and brown, on a 16-in. raceme, terminating a scape 4 ft. high, and now it is bearing some seed vessels. It bloomed this spring for the first time here.—W. FALCONER, in *Country Gentleman*.

White-flowered Borage.—When at Barcelona on May 5, I found on the rocks between the fort and the sea several plants of the white variety of the common Borage (*Borago officinalis*). I succeeded in bringing plants home in good condition, and they are now in full bloom. It is a very delicate and beautiful plant.—H. HARPUR CREWE, *Drayton-Beauchamp Rectory, Tring*.

THE BALANCE OF HEAT, LIGHT, AND MOISTURE IN FORCING.

THE adjustment of these agents in forcing fruits and flowers under glass is a nice problem that can only be approximately determined by long experience; but as the gardener has to trust largely to his assistants—who, though they may be willing enough, are usually learners only—he cannot fully utilise his experience in this way. It has been said that the temperature should always be in proportion to the light let in. In making such an observation one feels that everything depends, in fact, upon the intelligence and perceptions of the practitioner. My own conviction is that more harm is done to plants under glass by the ill-balanced conditions of heat, light, and moisture, than by any other single cause. A Cucumber or a Vine, for example, when growing out-of-doors, in favourable seasons seldom or never suffers from weakness or debility in the foliage, and can bear various vicissitudes of weather with comparative impunity; but under glass it cannot. Alternations of dull and bright weather, as every gardener knows, cause much mischief, and the evils accruing therefrom are in most cases aggravated by conditions greatly under the gardener's control. It is questionable if any real advance is made by keeping up high temperatures during dull weather, or if it be advisable to exceed the right temperature very much by fire-heat alone. On the other hand, during sunny weather, if constant, such things as Vines and Peaches, and many kinds of stove and greenhouse plants, will stand an intensity of sunlight that is surprising, if they have been prepared for it by growth made under favourable circumstances. I have subjected Melons and Pine plants

day after day to a temperature of 115° and 120° in bright weather without the slightest injury to the foliage, but always abated the temperature greatly at night or during dull days, making up for the loss of time when the sun shone. These extreme day temperatures were, however, only given when crops were being pushed on as hard as we dared, and I do not recommend such high figures, or anything like them, in ordinary practice. This season has been an exceedingly trying one for forced plants. In my own case low temperatures may be said to have been the rule, there has been so much dull weather;

and for the same reason forcing has been conducted on the "dry" principle, but little moisture having been given to Vines and Melons, &c. Evaporating troughs have long since been removed from the houses where portable, and fixed troughs have been kept empty from the beginning, yet I never saw the foliage or crops look more promising. Melons are splendid.

Respecting the adjustment of heat, light, and moisture in their relations to each other in plant culture, it seems to me that the great want of the present time is an instrument for gauging the intensity of the light, and which would be a guide to those in charge of hot-houses, just as the thermometer is in the matter of temperature. We all know pretty well that when we trust to our sensations to gauge the temperature we are apt to deceive ourselves very much, and I have a suspicion that a light measure would alter our practice in many things. I am not aware whether any such instrument is in existence or not, though I believe photographers have means of estimating the intensity or quality of light to some extent; but the man who will furnish us with such an appliance would benefit gardeners, and himself also, I hope.

J. S. W.

HEATING AND VENTILATING.

IN THE GARDEN (p. 494) in an article on heating by hot water the following passage occurs: "Suppose that an opening is made in a hot-house wall at the floor-level, and another in the opposite wall at the top; a current of air will enter at the bottom, and, passing in a straight line to the top opening, escape thereat, the rate at which it travels being proportionate to the difference in temperature of the outside and inside atmospheres. To secure an even distribution of

Boronia megastigma.

ventilating effect throughout the house, the ventilating inlets and exits must be set at regular distances, and the total area of the inlets should be more than that of the exits, to prevent back-draught." It is the last sentence of this quotation to which I wish to draw particular attention. It is satisfactory to see that demonstrated precisely—or scientifically, as one might say—which one has practised for long and recommended to others as correct practice. The advice given in the above quotation just amounts to this—that in ventilating Vineries or other fruit-houses as they are at present constructed most air should be admitted at the bottom or front ventilators, and least at the back, a practice which I have over and over again recommended in the culture of hot-house fruits of all kinds, and which has been as emphatically condemned by others, and by some noted cultivators too. In fact, the contrary practice to that recommended by Mr. Woodroffe is enforced in the great majority of instances, gardeners having some unaccountable prejudice against giving front air. Top or back ventilators are always opened first, and when those cannot be opened much further the lower or front shutters are opened a little. Yet the results of this practice are exactly what Mr. Woodroffe describes: there is an undue back-draught; the consequences are seen in the state of the trees at the top and bottom of the house—one portion of the stems is half starved and the other roasted. To equalise the temperature of lean-to or span-roofed houses in which the pipes are placed close to bottom ventilators, I estimate that a third at least more air should be given at the front than at the back; but in practice I exceed this myself, early in the season particularly. It was not, however, through reasoning the matter out, as your correspondent has done, but I was led to adopt the practice through observation of the effects of the different systems on the inmates of hot-houses. In the case of plant-houses where the side shelves are close to the ventilators, the plan of giving more front than back air does not answer so well, but that is the fault of the construction of the house and not of the ventilation.

J. S. W.

M. ANDRÉ ON LANDSCAPE GARDENING.

THE remarks made in THE GARDEN of the 7th June (p. 447) on my treatise on parks and gardens and their design were very gratifying to me. Praise and criticism coming from an artist who has been so long *facile princeps* among the landscape gardeners of England should be welcomed with interest and respect. I therefore thank Mr. Marnock for having given such a favourable opinion of my "Traité des Parcs et Jardins." It is well for the readers of THE GARDEN to have the artistic ideas of a man who has done so much for the art of gardening in England, and particularly when it is known that up to the present time he has published nothing on the subject. Mr. Marnock very kindly remarks that my book will have a large influence on the landscape gardening of France, and the terms in which he speaks of my work were very agreeable to me. I must equally thank him, too, for having expressed frankly his criticism in regard to certain points which he considers defective. He chiefly charges me with forming too many walks and drives, which, he says, destroy all freedom of view, and quotes Plate IV., page 385, in corroboration of this statement. I am glad of an opportunity to explain this matter, in order to show that my ideas in this respect are, with certain slight exceptions, similar to those of Mr. Marnock. I am so fully persuaded that unity and simplicity as regards effects and amplitude of view should dominate in landscape gardening, that I have repeated these precepts in nearly every page of my book. I do not want to bring forward statements from my "Treatise" to confirm what I say; but I may perhaps be permitted to quote the following (p. 376): "Too many curvilinear walks make gardens resemble a horse-training establishment. Walks and drives ought to lead naturally and agreeably to the desired place. To multiply them without reason is a fault very often committed both in France and in Germany. The opposite excess obtains in England, where frequently parts of parks very agreeable are inaccessible from want of approaches, the landscape effect only being studied. The happy medium is to form convenient and spacious drives and walks wherever there are interesting objects to visit, and to let them be seen as little as possible. The means to obtain this result are, among others, the judicious employment of screens and plantations, a slight depression of the surface of the walks or drives compared with that of the general level of the lawns around," &c.

No doubt it is well to hide walks as much as possible, and to prevent them from intruding upon and destroying fine landscape scenes, but in our effort to secure ample and quiet views it is easy to get into another kind of excess, and to place the garden on the same level as the sketch of a picture, which is to be seen from only one point of view. I gave an example of this kind of excess when I compared in several places the actual mode of tracing employed by landscape gardeners

in Germany, England, and France, and illustrated the subject by three engravings (see pp. 393, 394, and 396). I showed there that the first of these plans—the German one—presented a surface all cut to pieces, views little studied, and a total absence of any harmony in composition. The second—the English plan—is one of Mr. Marnock's own, although I did not name him in connection with it, as I had a slight criticism to make in regard to it. I remarked that in this park we found great simplicity in its details and special severity as regards the absence of walks—a severity which was carried out to an excessive degree, because it destroyed the means of getting easily about the various parts of the grounds a little way from the house. What seemed to have concerned him most was the creation of beautiful views from one point only—that of the terrace. The third plan—the French one—is mainly devoted to graceful curvilinear walks and drives, which also cut the landscape into childish details. I added, as a conclusion, that a happy medium between these three examples would constitute a satisfactory garden plan without losing the character of any of the styles, and that perhaps such a garden would be that of the future.

But, it may be said, why preach principles you do not practise? Are the parks you have laid out and the views you have published in conformity with the principles which you have laid down? I have always tried to make them so; but I have not always succeeded in persuading my readers to examine attentively my descriptions. If this had been done in Mr. Marnock's case, he would have seen, in speaking of the La Chassagne (Plate IV., p. 760), that I said myself that its plan would seem "bizarre" if the fact were lost sight of that the ground was very undulating and varied to excess. All the southern part of the park was on a very steep slope, which justifies bringing the walks nearer each other and their apparent parallelism. It is, therefore, difficult to criticise this properly from plans only. Something may be said in the same way in reference to the Central Park, New York, and similar works, the plans of which seem cut in pieces, whereas in reality vast spaces have been reserved, so that the breadth and unity of the scenes should not be spoiled.

It may be seen in various parts of my book (pp. 758 and 768) that I attack without pity the exaggerated cutting up of lawns. It will be admitted that it is very difficult to form a fair judgment on such delicate matters without seeing the parks and gardens referred to, and of which the plans very often give an imperfect idea. With these slight reservations I completely agree with Mr. Marnock's way of looking at such work, and the book which I have just published is, in its entirety, really an advocacy of Nature in the formation of gardens. I would not, however, wish to wholly exclude architecture from our art, but I have often said that it should only be introduced with great reserve and with consummate skill.

E. ANDRÉ.

Chinese Botanical and Horticultural Literature.—A writer in *Der Deutsche Garten* states that the imperial library of China contains 15,000 works on the cultivation of flowers and botany, whereof about 500 are devoted to the Rose alone. Such quantities of Roses are grown in the Emperor's gardens that the sale of the essence prepared therefrom annually brings £5000 into the treasury. Talking of Chinese botanical literature reminds us that the Japanese have already adopted the botanical nomenclature recognised in Europe, and their illustrations of the flora of Japan, to which the Latin names are attached, are exceedingly good.

Effects of Drought on Plants.—The amount of drought which some plants will bear with impunity is surprising. Dr. G. Schweinfurth, in Petermann's "Mittheilungen," gives an account of his recent journey across the Arabian desert from Heluan to Qeneh, and mentions some interesting facts concerning the vegetation. In Wady Qeneh, he states, no rain had fallen for six years, but some Acacias and Tamarisks were still green and flourishing and apparently unaffected, whilst the last traces of herbaceous plants had disappeared. In a more favoured part he found the valleys covered with *Salvia palestina*, a very handsome species 3 ft. high, with a profusion of sky-blue flowers.—*Gardeners' Monthly*.

Cut Flowers for Hospitals.—The practice of sending cut flowers to hospitals is becoming more and more general every year, and a great boon to these institutions they are, for by no one are flowers more highly appreciated than by their invalid inmates. Amongst the most liberal contributors to such places is Mr. Joseph Stevens, who has for some years past sent from his garden at Byfleet as many as two hundred, and even more, good-sized basketfuls of cut flowers during the season—an example well worthy of imitation. We learn too from Mr. Stevens that most of the railway companies have, for the last two years or so, carried all parcels containing flowers or fruit for the hospitals at half the ordinary parcel charges.—W. G.

OUTLINES OF THE PARTS OF PLANTS.

The figure or outline of a leaf, a leaflet, a petal, or any other part of a plant is of great importance in descriptive botany, though in each

Fig. 1.

case it is subject to more or less variation. In most plants the amount of variation is not great, and few words are needed to indi-

Fig. 2.

cate the shape of the leaves, &c. There is sometimes a considerable diversity in the root-leaves and uppermost stem-leaves of herbaceous

Fig. 3.

plants, and it is usual to describe root and stem leaves separately, albeit there is generally a gradual transition from one to the other.

On the other hand, *Lehneria umbellata*, an Indian Cucurbitaceous plant, presents almost every conceivable form of simple leaf, inasmuch that the leaves can only be described as polymorphous or pantomorphous. There is an admirable contrivance in Professor Oliver's "Lessons in Elementary Botany" for showing most of the principal forms with their designations at a glance, which is reproduced here. The terms apply equally to any flat parts of a plant, to simple leaves, the leaflets of compound leaves, to stipules, bracts, petals, sepals, &c., and the same terms are employed to indicate the general outline of an organ, whether the margin be entire, or toothed, or lobed. There are three groups of shapes, connected, of course, by every intermediate gradation. Thus in fig. 1 the forms are of the same breadth throughout their length, or broadest in the middle. In figs. 2 and 3 the broadest part is below the middle; and in fig. 4

Fig. 4.

the broadest part is above the middle. When one term inadequately describes the shape of a single leaf, &c., it is usual to combine two, as ovate-lanceolate, linear-lanceolate, cordate-ovate, &c.; and when the leaves or other organs of a plant vary, we say from linear to oblong or lanceolate, as the case may be. W. B. HEMSLEY.

ST. SWITHIN'S DAY.

THE rainfall proposes apparently to continue as vigorously in July as in June. If it happen that the flood-gates of heaven are still open on or during St. Swithin's day, there will be many superstitious people who, in addition to their present discomfort, will have the melancholy satisfaction of considering a downfall for forty days longer an absolute necessity; therefore, in the hope of dispelling somewhat the clouds, I propose, with permission, to say a few words as to the true state of the case. We all know the popular lines—

St. Swithin's day, if thou do'st rain,
For forty days it will remain;
St. Swithin's day, if thou be fair,
For forty days it will rain no mair,—

but we do not all know the reasons why we should not lay much stress upon them.

First.—By whose authority is it, we may ask, that St. Swithin is allowed of all saints in the calendar to be supreme in matters of weather? Other nations have their gloomy days, and, I may add, their gloomy saints with conflicting claims. The French, for instance, have two or three:—

S'il pleut le jour de St. Médard (June 8),
Il pleut quarante jours plus tard :
S'il pleut le jour de St. Gervais et de St. Protais (June 19),
Il pleut quarante jours après.

Secondly.—The "trough" or coffin of St. Swithin was moved from the outside to the inside of the church at Winchester on the 15th of July, 971 A.D., some hundred years or more after his burial. Now, the popular story is that the proceedings on this occasion were much disturbed by heavy rain, and that (owing, I suppose, to the disgust of the saint) the weather has ever since for forty subsequent days been governed by its own conduct on that particular one. But what was that day? It was the 15th, old style; that is, the 27th now. Is, therefore, the weather now-a-days to follow, not merely the translation of the saint's body, but also the subsequent translation of the date itself, or is it to desert the saint and cleave to the original date, that knows him no longer, as its day of departure? This difficulty alone might comfort the most superstitious.

Thirdly.—A quotation from "rare Ben Jonson," a century and a half before the adoption of the new style, proves that the 15th was old style ("Every Man out of his Humour," Act 1, s. 3):—

"Sordido (reading an almanac).—O, here, St. Swithin's, the xv. day—variable weather, for the most part rain: good. For the most part rain! Why, it should rain forty days after now, more or less: it was a rule held afore I was able to hold a plough, and yet here are two days no rain. Ha! it makes me muse."

Fourthly.—Perhaps the common-sense view is that after a dry spring the chances are in favour of a wet time after the middle of July. That the contrary may now be the case will be the earnest desire of all, but the probability of dry or wet must be left for the prophecies of the scientific and the weatherwise. Meanwhile, it can do no harm to beg St. Swithin to be propitious, unless, indeed, he desire to bear the blame of a drowning world upon his shoulders.—J. E. O., *Llandaff*.

— I send you a memorandum of the results, reported some years ago, of twenty years' observation at Greenwich concerning St. Swithin's Day. There were six years in which rain fell on St. Swithin's Day. During the forty days immediately following the 15th of July in these six years collectively rain fell on 110 days. St. Swithin's was a dry day in fourteen of the twenty years. Rain fell, in the subsequent 14 × 49 days, on 267 days. Now, 110 divided by 6 equals 18 and 14-42nds.; 267 divided by 14 equals 19 and 3-42nds, so that more rain fell in the forty days following St. Swithin, on an average, in the years in which that day was dry than in which it was wet. Therefore the adage is nought in every view of it.—ALICUS, in *Times*.

THE KITCHEN GARDEN.

THE POTATO CROP IN THE MIDLANDS.

It is instructive in a season like the present to note the effects of the weather upon the Potato crop. A Potato that will grow with vigour under unfavourable conditions must be the best Potato to plant generally where a crop is desired, for if we can but get tops we will get Potatoes in more or less abundance. In a quarter planted here early in May, which was as soon as we dared go on the ground, there is a marked difference in the appearance of some of the varieties, and I may just state that our climate is one of the latest and coldest in England. Among earlies Veitch's and Rivers' Royal Ashleaf and Mona's Pride look middling and all about the same, but are very late. Dalmahoy, from excellent Scotch sets, is affected with the "curl," which is spreading and getting rapidly worse, many plants being already ruined by it. Liability to "curl" is the worst fault belonging to this otherwise favourite variety. York Regents look considerably better, but are also suffering from want of warmth. Porter's Excelsior looks weak and bad, and will not produce much. Schoolmaster promised middling at the outset, but is beginning to look sickly, and will be an indifferent crop if the weather does not quickly mend. Magnum Bonum looks wonderfully well, and is much the best of the lot, as yet showing no signs of suffering. It is evidently one of the hardiest kinds. Champion and Grampian come next, and are shorter in the stem than Magnum Bonum, but look as well otherwise. I wish half the quarter or more had been planted with these three sorts. On an early border where the sets were sprouted some inches before planting, Kidneys look much better, and are a month before the main crop of the same kind, which were planted out earlier but not sprouted. The common Ashleaf is the most robust of the lot by a good deal, Mona's Pride is next, and Belvoir Prolific and French Prolific third. These last two are grown together, and I cannot at present distinguish the slightest difference between them in foliage, habit, flower, or crop. I begin to suspect they are the same. I had the one from an English house and the other from a Scotch firm, and both guaranteed true. This description of the crop, I may state, applies to other gardens in the neighbourhood. The weather has been most unfavourable—wet and cold. For the past week or more the thermometer has gone down every night to 44°, 45°, and 48°, and this in July. I am assured that snow was observed to fall two or three days ago on the hills a few miles off, and I am disposed to believe it. For days we have had a snowy-looking sky, but to-day the wind has veered round from north to south-east, and we have torrents of rain again. Over 7 in. of rain have fallen within the last six weeks.

J. S. W.

Sheffield.

Best Time to Sow Parsley.—The last week in July, or it may be a little earlier or later according to the season or locality, is the best time to sow Parsley. I have a bed of the Fern-leaved

variety that was sown last year about the time I have stated, which all through this cold ungenial season has given us an abundance of handsome curled leaves, and not 5 per cent. of the plants have or will run up to flower this year. It is the missing of the usual time of flowering that makes it so valuable, and this is brought about by sowing later than the usual or natural time. Every plant that was sown early last spring has "bolted" and been cleared away. I have adopted this plan for years, and invariably find this crop far more valuable than sowing in spring. I intend lifting some of the roots by and by, cutting off all the large leaves, and planting them 1 ft. apart in some convenient place where a frame or some other shelter can be placed over them at the approach of bad weather. In addition to this supply, two or three dozen roots will be potted into 6-in. pots, to be prepared for all emergencies.—E. HOBDAV.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Seakale from Seed.—"S. D." (p. 26), in estimating the qualities of Seakale from seed *versus* roots, forgets two or three important points. "Seedlings," he says, "at a year old, have only one crown, whereas plants obtained from roots have two or three; and therefore the yield from the same amount of ground may be safely reckoned at two-thirds more in favour of the plants from roots;" a statement by no means correct: indeed, I will undertake to grow as many single seedling plants in the same space of ground as "S. D." will grow crowns, under equal conditions; and the seedlings will be as good, and probably better, than the crowns. It is well known that cultivators thin out on the ground according to the crops, and I did not think it necessary to refer to such an obvious practice in the case of Seakale from seed. "S. D." further says that "plants from roots are up and growing before seedlings are above the ground." Just so; but the seedlings overtake and usually outgrow the plants from roots. Lobelias propagated from slips, as "S. D." knows well, and many other plants besides "are up and above ground" before seedlings; but by the end of the season the latter will have made twice as much growth as the cuttings, for which reason cuttings in that case are preferred. Seedlings are always the most vigorous. The fact that "S. D." plants his roots only 1 ft. apart, gives one a good idea of his plants. Most people find it necessary to allow 2 ft. and 2½ ft. between the rows, and I have covered the ground with seedlings 2 ft. by 2 ft., and the leaves were overlapping each other then. I recommended the plan of growing seedlings annually for forcing the same year as a good one for those who could not afford space to have two plantations on the ground, and I can with the utmost confidence recommend it wherever the climate is ordinarily favourable and the soil good. The culture that the market gardens give should produce grand plants.—J. S. W.

Peas in Pots.—There is something novel in the culture of Peas in pots for the production of an early crop under glass, but there is nothing more simple, and it is only a question of room. Dwarf kinds such as Unique, Early Gem, and Blue Peter, that usually grow 20 in. in height, will, in pots, not grow taller than 24 in. if the plants be kept near the glass, and have sufficient air. In raising a quantity I have found it to be the best and simplest plan to sow picked seed singly in small pots, and when in a gentle heat these are ready to repot, as they will be in about three weeks, to give them a single shift into 7-in. pots, in which the plants will do well. I have found the support of a single stick to which the haulm is tied at intervals to be ample, and if the plants produce side shoots ever so freely, as good branching kinds will, the single support will hold the entire plant erect. With Peas, as with other plants in pots, manure water or Clay's fertiliser sprinkled occasionally is productive of very good results. Under such culture as could be given them in a cold house, such kinds as Dean's Dwarf Marrow have produced pods of the finest quality earlier than the earliest white round kinds in the open air. With heat these might be ready a month earlier. Single plants so grown will produce from thirty to forty pods if well treated, and these will comprise some half-dozen gatherings. In a large place some 200 plants in pots would furnish a large quantity, and, if Dwarf Marrows, of such superior quality as to place the commoner whiterounds in the shade. In few places is any systematic attempt made to produce Peas earlier than can be obtained out-of-doors, but it is quite easy to do so as I have shown. Next to Potatoes no other vegetable is so acceptable at the table, and few can be forced more freely.—A. D.

Potatoes in Pots.—Whilst it is not possible to secure such fine tubers from pot culture as in frames and in the open air, yet really good Potatoes may be obtained in this way, and of even more delicate quality than in any other; the roots being restricted, and the haulm growth less rank, the tubers contain a larger amount of nutriment, and are more mealy. In numerous large gardens there is abundant space in orchard houses and Vineries that might well be

utilised in this manner. One strong tuber planted in either 9-in. or 10-in. pots will produce a potful of good tubers, and the earlier the sorts the better the results. It may be accepted as certain that the forcing of Potatoes is more easily carried out under pot culture than in frames. In the latter case the simplest method is by means of manure pits, especially where frames are placed over prepared hot-beds, but early in spring the maintenance of a high temperature in these is difficult, owing to their exposed surface. The best sorts for pot work are—of white Kidneys, the Ashleaf, and of white Rounds, Union or Early Market. Kinds having fairly dwarf haulm are indispensable. The tubers may be planted in bulk at any time from November onwards, and can be kept in any cool house, such as an orchard house, Peachhouse, or late Vinery, and be introduced into heat in relays as desired. I find the best results follow from the use of 10-in. pots, as in these the plants can well develop their cropping qualities. The sets are planted 3 in. below the surface, and if the tubers become exposed some more soil can easily be added. Clay's fertilisers sprinkled occasionally over the surface is productive of good results.—A. D.

Preserving Tomatoes.—I can hardly think that "A. F. P." (July 5) speaks from actual experience when he refers to ripe tomatoes in the following terms: "Covered with strong vinegar and kept in jars they can be preserved for months, ready when required to do duty as a salad." In the first place Italians, who know and employ almost every means of cooking and eating Tomatoes, never use the ripe ones for salad; those which are partly coloured only are much more piquant. And secondly, they maintain that unless the fruit is put into vinegar (in the case of pickles) quite green, the vinegar consumes the delicate outer skin and the pulp dissolves into liquid. My own experience fully confirms the popular idea; as a bottle of pickled Tomatoes was completely spoiled by three or four coloured fruits having been put into it by mistake. At the end of two months their skins gave way and spoiled the whole bottleful. That the failure was not an accident was proved by the other bottles of the same batch (three in number) which contained none but green fruits, and which were pickled in the same manner and with the same vinegar, keeping for a year in excellent condition.—CRAB.

A SUBSTITUTE FOR BOX.

THE prejudice that exists in favour of Box as an edging plant has often been a matter of surprise to me; nothing is so popular as Box, and, perhaps, nothing looks neater, and where it will thrive and it receives that care and attention which it requires to be at all satisfactory, perhaps no edging looks better (of course, I am speaking of a permanent edging); but, where it does not grow kindly or becomes neglected, nothing looks worse, and it is oftener seen in the latter condition than in the former. It has been frequently asked—and, if I recollect rightly, the question was mooted some time ago in THE GARDEN—if there is any substitute for Box. I feel happy in being able to answer in the affirmative, as I have for some years used a plant as an edging, not merely as a substitute but one which is decidedly superior to Box, and one, moreover, which, as far as I am concerned, will wholly supersede it, as, while it can be procured, I am determined never to plant Box again, even if sure of its thriving. I have a small Dutch or Italian garden in front of my house, the whole of which was originally edged with Box on gravel. The Box always wanted mending, and I was compelled to have a reserve for patching purposes; ultimately, I threw up the Box in despair (it had nearly gone off of its own accord) and set myself to solve the problem—is there nothing as good or better than Box? Having a very large collection of Saxifrages, and remembering having seen that rather coarse plant *S. umbrosa*, or London Pride, used as an edging in places about towns where no other plant could live, I cast my eyes on the *Geum* section of the leathery-leaved Saxifrages; this section has, in the type, neat orbicular or reniform leaves. Some of the forms, such as *crispa*, *gracilis*, *dentata*, and *densa*, are beautiful miniature plants, none of which would disgrace the choicest collection of Alpines. *Saxifraga Geum densa* was the one I took in hand as a substitute for the precarious Box, as, owing to its tufted, dense habit, it can be broken up and will go farther in planting than the others, though, as plants, *gracilis* and *dentata* are more charming. A small tuft of *S. Geum densa* will break up and plant a garden, and I only wish those who care to see a neat, durable, and easily-managed edging would call and see my garden. Certain I am that the plant if once seen would be planted by the mile.

The advantages of this edging plant are its neat, dwarf habit, its permanent lively colour, and the facility with which it may be propagated and planted; unlike Box it never requires training or clipping; it will thrive as well in towns as in the country, in any kind of soil from damp clay to dry gravel, and it may be planted at any or at all seasons; and, whereas Box, besides the labour attending clipping, often looks shabby a long time after that operation, this

edging has one cheerful, uniform appearance at all seasons. It seems a plant peculiarly adapted for the indifferent soil too often met with in town gardens, actually looking neater in poor, sandy material than in a rich soil. It would make a fine plant for bands and belts and ranges of green in city courts and squares, where a blade of Grass could not live, and as a green massing plant in parks and public gardens it would be invaluable; bands and belts of Ivy or figures on gravel would be much improved by a band of this plant round them, the pea-green of the Saxifrages relieving the dark hue of the Ivy, and even in the finest of kitchen gardens where tile or stone edgings are sometimes used, an edging of this plant on the gravel side of the tile would give the garden a sprightly appearance at all seasons of the year.

I have said this edging is permanent, and so it is; however, where extreme neatness is required it may necessitate re-planting every third or fourth year, an operation which does not involve a tithe the labour needed in re-planting Box. With a clean sharp spade commence at one end and shovel it off level with the ground, place it neatly on one side, leaving the roots of the cut-off edging in the ground. This is of advantage, and keeps the ground solid and firm where the new cut is to be made. Stretch the line exactly where the old edging grew; cut down a nick $1\frac{1}{2}$ in. or 2 in. deep, and having the old edging before you, select bits of an equal size and plant them as you would Box, only the operation can be performed with greater rapidity. I would undertake to plant 80 yds. or 100 yds. in a day. It will be found that of the old plants cut off with the spade every bit will have roots enough to ensure growth.

Ormskirk.

THOMAS WILLIAMS.

GARDEN DESTROYERS.

THE MAY BUG IN FRANCE.

WHILE we in England have much to endure from insect pests we have reason to be grateful for the comparative immunity which we enjoy from the ravages of that greatest of garden destroyers—the cockchafer grub. Those who may never have had the opportunity of witnessing upon a large scale the ravages of this insect can scarcely form an idea of its voracity and the havoc it is capable of working in a short time. The "ver blanc" is a name of terror to the Norman gardener and peasant farmer, as well it may be, for it so often sweeps off in the most complete manner the results of his labour and skill. Nothing appears to enjoy an immunity from its attacks; trees are denuded of foliage by the perfect insect, and all kinds of vegetables and flowering plants, and even young trees, have their roots devoured by the larvæ. Pasture land, too, especially when in the neighbourhood of woods, is often so worked by the grub as to be entirely ruined. There is much wood in some parts of Normandy, and these districts are apt to suffer terribly, the woods appearing to harbour the insects, which descend in clouds upon the country round about, depositing myriads of eggs in the gardens and fields. The loss annually sustained by the ravages of this insect must be enormous, and it is by no means rare to hear an unsuccessful cultivator attribute his failure entirely to its influence. A very striking instance of the destructive power of the larva once came under my observation. An individual of good abilities rented a piece of ground of several acres for the purpose of converting it into a nursery and market garden. It was cropped partly in the usual manner with vegetables and partly with shrubs and standard Briers for budding. All went well until about the time when Rose buds were well taken, when the grub commenced its attacks, and in the course of a month scarcely anything remained uninjured. Vegetables of all kinds, shrubs, and Briers all fell a prey to this voracious insect. Of 7000 Briers scarcely as many hundreds were left. Searching for and destroying the grub seemed to be of no use; the soil was alive with them, a single spadeful of mould bringing to light a dozen large larvæ. When at Mr. Wood's nursery, at Rouen, some years ago, I saw a number of fine standard Rhododendrons which were destined for the Paris Exhibition of 1867. I was afterwards informed that the grub had made a clean sweep of them. The trouble and annoyance which the larvæ are capable of inflicting upon the flower gardener are very great. Beds of Pelargoniums are often cleared off, and the grower has to keep a reserve stock in hand to fill up the gaps which occur. Gardening under such circumstances becomes not only tiresome, but very unsatisfactory, and those who have once had to contend with this scourge will estimate at its full value any immunity which they may enjoy from its attacks.

J. CORNHILL.

Mice and Yuccas.—A fine plant of *Yucca gloriosa* came by its death during the past winter in an unusual way. Driven doubtless by lack of food, a mouse or more than one attacked the plant,

which grew just at the head of the lake in the grounds at Heckfield, and, eating its way in the case of each of the three stems into the centre of the wood just above the ground, bored holes about 1½ in. in diameter some 15 in. upwards, so that the entire plant collapsed. This incident may prove an inducement to those who have Yuccas in their gardens to occasionally look over their stems during the winter months, and thus check in time the depredations of vermin.—A. D.

Gooseberry Caterpillar.—For many years we have had a branch of the common Gorse when in flower put into the middle of each Gooseberry bush as early in the spring as it can be procured, and we find it effectual in keeping them free from caterpillar.—M. E. T., *Belfast*.

Sawdust v. Slugs.—I have found the following plan of getting rid of slugs very efficacious, namely, sprinkling sawdust round the plants as one would quicklime and soot. The latter when once wetted lose their effect, but sawdust retains its virtue however wet, and, sticking to the slugs, prevents their approach. When dry, slugs, &c., detest it.—ESTHER E. CLARKE, *Sunnyland, Ramsey, Isle of Man*.

ANSWERS TO CORRESPONDENTS.

Gooseberry Caterpillars.—How am I to get rid of these? My Gooseberry bushes are quite ruined by them.—CONSTANT READER. [Freshly powdered Hellebore will kill the caterpillars; but care in st be taken to free the fr from it before it is used].

Vine Leaf Excrecences.—H. F. B. The little green excrecences on the under sides of your vine-leaves are harmless. They simply indicate that the vivery in which the leaves are produced is kept too close and moist.

Diseased Cucumbers.—In the midst of a successful growth of Cucumbers I found lately a disease showing itself in the form of a brown crust on the rind of the fruit. Is it fungoid?—AMATEUR SUBSCRIBER. [There is no fungus on the specimen sent. We should be inclined to refer it to a form of "gumming" as cultivators term it, but we do not know the cause or cure.—W. G. S.]

Cheap Pits.—What is the cheapest sort of pit? It does not matter about its being at all ornamental, cheapness and usefulness being my aim, and I think of putting it up myself. Is there a useful and cheap heating apparatus?—ROSE. [Pits with turf walls are the cheapest. Watson, of St. Albans, has what he calls a guinea boiler.]

Hardy Palm Flowering in Hants.—We have on our lawn a dwarf Palm, which will shortly be in full bloom, and, thinking it unusual to see such in England, I write to ask if you know of another. Our plant is of about seven years' growth, and has never been protected by any covering during winter. Last year it bore four spathes of bloom, and this year six. Our gardener has given me the following dimensions of this plant, viz., "Height 5 ft. 4 in., width 6 ft. 8 in., circumference 20 ft., height of trunk 2 ft. 10 in., circumference of trunk at base 2 ft. 10 in."—A. B. [There are two fine plants of the hardy Palm at Heckfield, growing in naturally sheltered positions, but without any other protection. They are now from 11 ft. to 12 ft. in height, and the same in width. Many of the leaves measure 2½ ft. in width, and the trunks of the plants are upwards of 4 ft. in circumference. Both are now bearing seven flower spathes, which are at least 2 ft. in length. The late severe winter does not appear to have injured them farther than slightly browning a few of the oldest leaves.—A.]

Potatoes Failing.—The same results that have befallen "R. G.'s" Irish Rocks (p. 24) have also befallen many other breadths of Potatoes that were planted early in stiff, cold land. Owing to continued heavy rains and an exceedingly low temperature, the sets pushed weakly, imperfect shoots, and these very largely rotted before coming through, or were eaten off by slugs. In many cases in this locality large breadths of early-planted Potatoes have been ploughed up, the sets having rotted in the ground. It is a mistake to plant Potatoes too early, and especially in soils that are cold, stiff, or retentive of moisture. In such, and during such a season as the present, failures in the potato crop must be frequently looked for.—A. D., *Bedfont*.

Cutting down Pot Rhododendrons.—Kindly inform me whether large specimens of Rhododendrons, which have been grown in pots for years, and which are now getting leggy and unwieldy, may be safely cut back after flowering, and if so how closely to the stem may the knife go?—H. B. [The ordinary varieties of R. ponticum may be cut down at almost any time of the year, but the operation is best performed just after the flowering season. If the plants in question are greenhouse kinds, they may be cut back after flowering, leaving about 1 ft. or 1½ ft. of stem. After the operation they should be kept in a close and cool house or frame until the shoots are a few inches in length, when they should be gradually hardened off.—G.]

Climbers and Wall Plants.—The names of a few greenhouse climbers, flowering and evergreen, which would quickly cover the back wall (5 ft. high), and roof of a newly built house, would greatly oblige me. The conservatory has a southern aspect, and will be heated moderately in winter by a fire. Which of the red Tacsonias and what Acacia would be most satisfactory for the purpose? Should these plants be grown in large pots, or in borders? The latter in this case must be necessarily over the line. What would be the proper winter temperature for these and other conservatory climbers? A few names of hardy climbers for the brickwork outside the house will also be considered a favour.—M. [For covering the roof I would recommend Tacsonia insizmis, T. exoniensis, Lappageria rosea and alba, Solanum jasminoides, Tropaeolum Bell of Fire, Colchica scandens variegata, Clematis Lord Derby, Fuchsias of various free-growing kinds, and Acacia Ricciana. For covering the back wall I would select Habrothamnus elegans, Acacia dealbata, A. lophantha, Abutilon Thompsoni, Swansona Osborni, Plumbago capensis, Rhyncospermum jasminoides, and Bougainvillea glabra. The last-named plant is generally considered to require a stove, but I have grown it successfully where the frost is only just kept out in winter, cutting it well back in spring to get new growth, which produces flowers abundantly in August and September. Myrtles are likewise good wall plants, as are also the more robust-growing scarlet Pelargoniums, including the double-flowered kinds. In a light house I have had scarlet Pelargoniums in bloom pretty well all the year

round. The Heliotrope, again, does well, and a plant of it should be included for the sake of its flowers for cutting. It must have a light position. If a border can be obtained over the line of sufficient depth without becoming too hot and dry, I should prefer planting out to pot culture. If this, however, cannot be done good-sized pots must be used, and as the plants cannot often be re-potted the pots must be well drained, and the soil as full of fibre as possible, mixing with it a few crushed bones. The winter temperature may range between 40° and 50°, taking the former as that of the night temperature and the latter as that of the daytime, but a degree or two above or below these figures will not matter much. If the house is expected to produce plenty of blooms in winter 5° higher may be allowed. Hardy climbers may consist of Tea Roses, Berberis Darwini, B. stenophylla, Ceanothus azureus, Crataegus Pyracantha, Wistaria sinensis, Jasminum nudiflorum, Forsythia viridissima, Chimonanthus fragrans, Pyrus japonica. Clematises consisting of various hybrids, C. montana, and C. flammula, Garrya elliptica, Escallonia macrantha, Honeyuckles, Jasminum officinale, and Virginian Creeper.—E. H.]

Beetles.—Is the enclosed beetle destructive.—F. B. [The beetle sent is very destructive to the gardener's worst enemies and should be carefully petted and encouraged. It is Ocyptus o'eus, one of the Staphylinidae, sometimes called Devil's coach horse.—W. W. S.]

Cucumbers.—Amateur.—The soil sent was mixed with a fungus-like substance, which seems to spread on the surface. We should recommend that the earth in the cucumber frames be carefully removed, and a new soil introduced.—W. W. S.

Conifer Seeds.—A. M. A.—Sow them now in pans filled with loam, and place them in a cold frame. The only care required is not to keep them too wet.

Diseased Peach Leaves.—M. S.—They are blistered, the result of the unfavourable season which we have had. See some remarks on this subject in another column.

Osiers.—C. M. A.—Apply to Mr. Sealing, Basford, Notts.

Eradicating Gorse.—What is the best way of getting rid of Gorse? That to which I refer has been grubbed up, and grass laid down in its place, but it has grown up again in the course of two years as thickly as ever.—C. A. S. [It is, doubtless, the seedlings that come up. Pursue the course which you have taken in the first instance, and you will ultimately succeed.]

Names of Plants.—M. T.—1, Hemeroallis graminea; 2, Francoa ramosa. E. St. A.—Escallonia. J. H. V.—Probably Calceola esculenta, a common plant in all the West India Islands. F. T.—1, Next week; 2, Hemeroallis graminea; 3, Potentilla atrosanguinea. T. B. A.—1, Apparently Campanula carpatia; 2, C. pusilla alba; 3, Viola cornuta. C. B. K.—1 and 2 varieties of Begonia Rex, others next week. R. J. R.—1, Brachycoma lanceolata; 2, Boronia Drummondii; 3, apparently Eriostemon myoporoides. C.—Viola blanda. D. E.—It looks like the variety named Holyrood, but we cannot undertake to name florists' flowers, which should be submitted to some specialist. J. E. M.—Digitalis lutea, probably escaped from some garden.

Questions.

Imported Orchids.—Some time since I bought several lots of Orchids as imported, principally Celygones and Cyathidiums. These are now making young growths, but do not seem to be pushing roots. Should they be potted when the shoots begin to grow, or should I wait until new roots show themselves? To any experienced Orchid grower who will answer this question I shall feel deeply indebted.—W. B.

Single Cordon Pears.—Will any experienced fruit grower kindly give his experience as to the most satisfactory way of training, or rather pruning, single cordon Pears? I have a wall planted entirely with Marie Louise, worked on a strong growing kind, probably Beurrd de Aumalis in the Quince stock. They have been planted three years, are now about 4 ft. high, and making a robust growth, the shoots being from 12 in. to 16 in. in length. When is the best time to summer prune in order to produce fruit spurs? I tried two different periods last year but without diverse results. Rightly or wrongly, I have no faith in the finger and thumb business; I believe that only results in the production of a mass of weak unripe wood. The trees are trained vertically.—A. D.

Diseased Cedar of Lebanon.—Can any remedy be suggested to save a magnificent old Cedar of Lebanon Tree which is looking very unhealthy, and which shows no sign of growth. On examining its base a quantity of black, gummy substance was found oozing out; the bark underneath the soil appears dead and exhibits traces of fungus. One of the roots was examined and found to be quite decayed, the others have not been disturbed. Fresh soil has been from time to time spread over the roots; could this possibly have injured the tree?—CEDAR OF LEBANON.

Rhubarb.—Will some of your correspondents say what is the heaviest stalk of Rhubarb which they have gathered about this time of year?—M.

The New Forest.—Instead of submitting to the passing of an Act of Parliament such as that now brought before the Houses for the amendment of the Act of 1877, it is high time that the public became aroused to the necessity of taking immediate steps to secure a restoration to the state of those rights and privileges which were forfeited by that Act. The loss to the nation is incalculable, and the proposed amendment can only aggravate the situation by prolonging the period of injustice, and by deferring substantial legislation upon the much-vexed question of the rights of the commoners. In the prospect of the speedy establishment of a school of forestry in our own country, the 43,000 acres of land now devoted solely to the gratuitous benefit of the commoners might be made available for the training of a body of young men in the principles of draining, enclosing, trenching, planting, pruning, and future care of our principal forest trees. Her Majesty's Commissioners of Woods are fully alive to the importance of the object to be attained; but it is only by keeping the subject well before the public that the desired result can be arrived at. From the year 1788 down to the present time protests have been made by Commissioners, and it is to be hoped that the nation will no longer rest content with the mere patching up of Acts which in practice prove unworkable.—A. J. B.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

OUTDOOR GRAPE CULTURE IN ENGLAND.

IN the present depressed state of agriculture the prospects of Grape culture out-of-doors in some of the more favoured parts of the south as a commercial industry might be advantageously discussed. To all appearance, the culture of Grapes under glass for market purposes has seen its best days. The impulse which the trade received many years ago induced a few to embark in that business exclusively, and these early beginners had the ball at their feet for a time; but in a few short years there came a reaction. Numbers began to grow Grapes for the market, both in England and Scotland, and, owing to the increasing practice of growing late Grapes in private gardens, these establishments were not only better supplied than they had been before, thus reducing the demand, but in numbers of instances helped to glut the market. Then the Channel Islands, which had always contributed largely to the supply, began to pull up and send a better sample than they had done before, as well as an earlier supply, and, having a milder climate, they have been able hitherto to hold their own even against Continental competitors, and have seriously affected the home trade. The result now is that Grape growing at home has become a rather precarious speculation by itself, and those who began in the confident expectation of making rapid fortunes by the business have enough to do to make it pay; indeed, some noted cultivators have converted their Vineries to other purposes within the last few years. Another thing which has helped to reduce the price of Grapes is the more abundant importations of Pine-apples and Melons, &c. The St. Michael's Pines, coming in at a time when Grapes are dearest, have been extensively used as a substitute. The effect of these various causes has been a very great reduction as regards prices, as any one may see who looks over the market list now and ten or fifteen years ago. Depression of trade has no doubt, too, had its effect on the prices of fruit as on other things: but it is well known that during the prosperous years through which we have lately passed the tendency of prices has been downwards in the Grape market, and nowhere more conspicuously than in Covent Garden. In short, it may be doubted if any person of experience in Grape culture could now be found who would invest capital to any extent in the culture of Grapes for the market under glass.

At certain seasons in London and in the chief provincial towns Grapes of first-rate quality will always fetch fairly remunerative prices, but nothing more; it is, however, very seldom that any grower succeeds in producing good crops with any degree of constancy, and he therefore cannot calculate on such prices. At the present time, and for some months past, when Grapes are supposed to fetch the best prices, the amount offered to growers by buyers in Covent Garden has been very little. We have heard of some of the most noted cultivators parting with their crops at 2s. 6d. per lb. in May, a price which can barely pay working and other expenses in the production of early Grapes. Fine English Grapes have been plentiful in the provincial markets at 3s. of late—retail price; and they will continue to decline now till near the end of the year, during which interval Continental cultivators will provide the main supply. Under these circumstances, it is clear that unless something can be done to cheapen the production of home-grown Grapes, the market grower will soon be in very much the same position as the English farmer is at the present time. If, however, dessert Grapes can be ripened out-of-doors in England, their culture should cost little, if anything, more than it does in the north of France, near Paris, from whence all the Grapes that supply that city from August till November or longer come; and it remains for us to consider what the prospects of success are in this direction. For my own part I have a settled conviction, founded upon observation and experience, that outdoor Grape culture can be accomplished successfully; and it would be strange if the noted skill of English horticulturists was not equal to the task if they chose only to apply it in the right way.

Climate and Varieties.

About Fontainebleau and Thomery, where the Chasselas de Fontainebleau Grapes are grown, everything denotes a thriving industry and considerable wealth. The first question an Englishman acquainted with the culture of Grapes and the capabilities of his own climate, asks is, "Why cannot the same be accomplished in the south of England?" The only doubt ever entertained or expressed on this head, so far as I am aware, relates to the climate, which is said to be too cold; a

doubt which however is not entertained by those who have made the attempt on a small scale, or any who have had opportunities of estimating the matter aright. Crops would probably be a little later, but I do not doubt for a moment that if anyone having sufficient capital was to employ a skilled Vine grower from the north of France in some favourable locality in Kent or Surrey, or any southern county where the subsoil is dry, he would prove conclusively that the expectations of those who advocated the outdoor culture of Grapes in England are well founded. It has not now to be proved, indeed, that the Grape will ripen on the open wall in many parts of England, and that too with the utmost regularity—early varieties at least, like the Royal Muscadine (the Chasselas de Fontainebleau of the French), and a really excellent grape it is when ripened in the open air. There are, too, other varieties quite as early as the Royal Muscadine, but none of these possess so many good qualities as an early Grape. It is a vigorous grower, a sure bearer, and a good setter, three very important qualities, and it is also a good keeper after it is ripe. It is saying a good deal for this variety that it has held its own from time immemorial, and is still one of our favourite early white Grapes. These good points the Vine growers in the north of France have understood, and hence they have stuck with commendable persistence to the Royal Muscadine alone—at least the proportion of other sorts grown is very small. It is undoubtedly the Grape to be depended on in this country, wherever the culture of dessert Grapes is attempted. Aged Vines of it and plenty of young ones are to be found in England out-of-doors, as far north as the Midlands at least, and bearing with a degree of regularity that would surprise those who are accustomed to think that good Grapes cannot be produced in this country.

The experiment of growing Grapes for wine-making purposes at Cardiff, during a succession of exceptionally late seasons, and in one of the cloudiest parts of England, has proved that the Grape will ripen without even the protection of a wall, though it is not proposed here to attempt anything more than wall culture. In the south of England we have frequently seen very good samples of Muscadine grown on cottage fronts and in gardens. On the London, Chatham, and Dover line last year one small cottage covered on its sunny side with this Vine was particularly noticeable. The Vines had been trained in the most methodical fashion, evidently by a skilled hand, and bore a fine crop of bunches just about beginning to ripen at the end of the second week of August. Such examples show what can be done by culture, and examples of Vines growing and bearing almost unweared for are common enough in the southern counties. I am acquainted with one fine old Royal Muscadine Vine in front of a large farm house in Nottinghamshire, and about seventy years of age, that has not failed to bear and ripen large quantities of fruit every year for a long period, and it is at this time maturing a heavy crop. I saw and tasted the fruit from this Vine last autumn, and thought it excellent. It was quite as good as samples which I have seen from Fontainebleau. At Bury St. Edmunds, too, and at Woodstock, Mr. Derkin and Mr. Fenn respectively have, as is well known, grown fine Grapes out-of-doors. Indeed it has been proved without doubt that the Grape can be ripened successfully in many parts of the south of England; and its culture for market needs only to be tried on a large scale in order to demonstrate conclusively the capabilities of our climate in that respect.

Culture.

As to the practical culture of the Vine out-of-doors, that is a subject which has been more than once treated of in the pages of THE GARDEN. My object at present is to direct fresh attention to the subject of outdoor Grape culture against walls, and its practicability as a commercial undertaking. I would only point out that in making such an attempt, much would depend upon situation and soil; but in the fertile vales of Kent, Surrey, Hampshire, and elsewhere, no doubt these could be found in suitable conjunction in scores of places. As to original outlay that would not be serious. The heaviest item would be the Vine walls, which need not be high nor yet expensive, and a great extent of them may occupy a comparatively small piece of ground. In France the walls are not often more than 6 ft. or 8 ft. high, and are inexpensively constructed. Such low walls are approved of by some for the reason that they are more benefited by the radiated heat from the earth than they would be if they were higher. A higher wall would certainly afford more training space, but the advantage in this respect is not very apparent, as the higher the walls the farther they would need to be apart, in order to admit the sunshine to the Vines and borders behind, for in such Vineyards the walls run in parallel lines. Copings are required to throw off frosts and rain, but for low walls expensive glass copings would be superfluous. In France the frosts are more severe than with us, but common slates and tiles projecting about 1 ft. or less from the wall are found sufficient with the aid of coverings in spring and unremitting attention. In this country root treatment would be the most important affair,

as the timely ripening of the crops and the wood would greatly depend upon the character of the soil and its depth. Not that expensive or elaborately-prepared borders would be at all necessary, for the natural soil, enriched by manure in the usual way, would be quite good enough; and rich and deep borders, that find favour in cultivating the Grape under glass, would be out of the question. The object of the grower would be not to produce wonderful bunches, but good and regular crops of fruit that would find a ready market and appreciative customers. For an outside Vine border we believe, speaking from a pretty intimate knowledge of the habit of the Vine, that from 15 in. to 18 in. would be ample depth, and for manures we should be disposed to use bones and inorganic manures principally. The borders would have to be also thoroughly drained and laid with a decided slant to the sun; and if the whole Vineyard could be sheltered from the north and east by hills or woods at a distance it would be a great advantage.

Cost.

With regard to the general culture of the Vine out-of-doors and the cost of labour, the first would be found to be exceedingly simple and easily learned, and the second would be less serious and less arduous than the culture of not a few other garden and farm crops. Much of the work pertaining to Vine culture can be done as well if not better by women than men. What duties the latter are required for are training and pruning chiefly—duties which are mostly over by midsummer, as all pinching and thinning could be performed by women. It is well known that in private gardens Vines require the least attention on the average throughout the year of any crop in the garden. In some of the best Vineyards under glass in this country hardly more than a tithe of the strength that would be required to maintain a general nursery or garden of the same extent in good order is employed. A push has certainly to be made at the thinning season, which occupies a week or two, but after that the work principally consists in watering and attending to borders and pinching the laterals on the Vine shoots. In outdoor culture it must not be disguised, however, that much would depend upon the proper and diligent use of all means likely to promote success, and attention to those little points of culture in which the Continental gardeners excel us so much.

S. W.

DESSERT ORANGE CULTURE.

Few of the fruits given to man contribute so largely to satisfy the daily needs of humanity as the Orange; entire provinces of the fairest portions of the globe are devoted specially to the production of this inestimable fruit, and worthily. The extraordinary property of keeping both outwardly and inwardly all its excellent qualities is possessed by this fruit alone. The origin of the Orange appears to be lost in antiquity, and, as no specimen of a wilding in its original habitat has been discovered, it seems as if the fruit, like Minerva, had sprung into being perfect at all points. It is alike to be discovered in the mythology of Europe, and in the remote and fabulous antiquity of China, a very fine and fruitful specimen being figured in the "Willow pattern" plate.

In the time of John Evelyn dessert Oranges were evidently grown as a luxury, as he alludes to the fact that he plucked as good fruit from his own trees as he could wish. The "Orangerie" at Versailles achieved a lurid reputation in the earlier days of the trouble and confusion preceding the great Revolution; but the Orange trees of that time grown as ornaments in royal and princely gardens were the bitter variety known as Seville Oranges. An Orangerie, generally dark and dismal, was at one time as much an imperative appendage to a well-kept garden as the forcing house; but it is not easy to understand why it happened that few gardens possessed the dessert varieties, as they require no better climate or treatment than the bitter Oranges, and are equally liberal in producing both flowers and fruit.

It is well known that Orange trees cultivated in the usual way in France or England never give fruit at all eatable, solely from the lack of heat at their ripening period, late in autumn and winter. In Grenada (West Indies) they commence to ripen towards the end of October, in a temperature varying from 70° to 80° or thereabouts; their flavour there, freshly gathered from the trees, is so delicious that they are far superior to those we receive from St. Michael's and other places, all of which are gathered before they are ripe. In our tropical orchard-house Oranges ripen in October, November, and December. How agreeable to be able to gather a portion of the Christmas dessert from one's own trees!

As an ornamental tree in the greenhouse and conservatory it is an old friend; and perhaps no tree in the known world has suffered, and does suffer, such vicissitudes, yet living and seeming to thrive under them. It glories in a tropical climate, and yet lives and grows after being poked into those cellar-like vaults used for its winter quarters

on the Continent; it gives flowers in abundance under such treatment, and would even give its fruit—albeit uneatable—if permitted. Nearly the same kind of cultivation has been followed for very many years in England; it has rarely had heat sufficient to keep the tree in full vigour; and its roots, in pots or tubs, must have suffered severely from having been placed out-of-doors in summer on our cool damp soil, and in winter on a stone floor still more cold.

Varieties of Orange.

In cultivating the Orange for its fruit, the first consideration is to procure some of the most desirable varieties, such as the delicious thin and smooth-rinded Oranges which we receive from St. Michael's, the Maltese Blood Orange, and the Tangierine. The Tangierine is of all Oranges the most desirable, as it is a most abundant bearer, and produces fruit of as fine a flavour in the orchard house as at Lisbon. It requires, however, different treatment from that of the usual orchard-house trees; for, although comparatively hardy, it must have the shelter of a greenhouse or conservatory during the year, so as to be protected from the summer's rains and the winter's frost.

There are two methods of cultivating this most charming fruit, the Tangierine Orange. The first and the most eligible is by forcing, so as to have the fruit ripe by October; if properly treated they will then be in the highest perfection, their skins bursting with their delicious juice. To carry out this mode of culture the trees should be removed to the Pinery or Vinery, where early Grapes are being forced, early in the month of January; the pots plunged in gentle heat in the high temperature of such houses. They will blossom towards the end of February, and should be treated as all other kinds of fruit trees are when in bloom—*i.e.*, the pots and the lower branches may be syringed, but the blossoms kept dry. They will set large crops of fruit, which, if too much crowded, should be thinned. If possible, the pots should be kept plunged, or stand on a heated surface all the summer in the temperature of the Pinery or forcing Vinery; they will then ripen their fruit early in autumn, when Oranges are rare. The other method is to keep the trees in the greenhouse or conservatory all through the winter, and remove them to the orchard-house in May; they will blossom in May, and set their fruit, which will increase in size slowly all the summer, but not ripen till the following year, in June or July. The trees should be removed from the orchard-house to the greenhouse at the end of September. This is not so satisfactory a method of growing this very pretty and nice fruit as the former, but the trees in bloom and in fruit in May are most interesting objects in the orchard-house.

The houses best adapted for their cultivation are the large span-roofed, 24 ft. wide, 6 ft. high at each side, and 15 ft. high in the centre. A house of this size will require eight 4-in. hot-water pipes, four on each side, as artificial heat is required all the year to ripen Oranges in one season perfectly. A smaller span-roofed house, 5½ ft. high at each side, and 12 ft. high in the centre, heated by four 4-in. hot-water pipes, two on each side, is almost as eligible for Orange culture as one even of the larger size. A house of these dimensions, with a central path, and a border on each side planted with Orange trees, would form a pleasant and productive Orange garden; but to form an Orange grove, so as to have trees of fine growth, and to give abundant crops, the larger house must be resorted to.

A Tangierine Orange house is a pleasant addition to the fruit garden; the trees planted in a 14-ft. span-roofed house, the borders heated with hot-water pipes, and the air with hot-water pipes above the surface, would be both fruitful and beautiful at all seasons. Their habit is dwarf and yet graceful, from the smallness of their leaves. They seldom, even in the Orange gardens of Portugal, attain a greater height than from 5 ft. to 7 ft. This delicious little Orange is only eaten in perfection when fresh from the tree. In Lisbon it is sent to the dessert in clusters with leaves attached to them; unless these are quite fresh and green when the fruit is served, it is not reckoned in full flavour. If grown in the tropical orchard-house, the trees should be placed in the coolest part of it, and have abundance of air in mild weather in winter; they will then bloom later, and set their fruit with greater certainty.

The best form of tree for an Orange garden under glass is the round-headed, a form which it seems to take naturally; for if it is endeavoured to be cultivated as a pyramid, its lower branches soon become weakly and unhealthy. If trees with stems 2 ft. or 3 ft. in height are planted, the lower branches may be gradually removed till a clear stem of 5 ft. in height is formed, and this height will be found sufficient. They may be planted from 5 ft. to 6 ft. or 7 ft. apart, according to the size of the house, and the room which can be afforded for each tree. It must not be forgotten that in small houses the heads of the trees may be kept in a compact state by summer pinching, and in large houses be allowed a greater freedom of growth, so that the owner of an Orange garden in England may sit under the shade of his own Orange trees.

The St. Michael's Orange is well known for its thin rind and excellent flavour. A very superior sort, which I received direct from St. Michael's, seems to be a most prolific variety, for trees only 1 ft. in height are full of blossoms and fruit. The treatment recommended for the culture of the Tangerine Orange may be followed in cultivating this sort. Tangerine and St. Michael's Orange trees, planted in the borders of a large span-roofed house, furnished with enough of a heating apparatus to keep out frost, and the borders heated as before mentioned, will grow well and bear well; so that it is quite probable our markets will be supplied in the autumn with Tangerine Oranges freshly gathered from the trees, and full of the delicious aroma for which they are renowned.

There are several kinds of Oranges cultivated in the Azores besides that thin-rinded excellent sort known *par excellence* as the St. Michael's. The following kinds I have recently received, and give their descriptions: The Egg Orange, oval, very handsome and delicious; the Plata or Silver Orange, very delicious; the Long Orange, a remarkable sort, very fine and rich; some specimens of this, sent to the Royal Horticultural Society, received a special certificate. The White Orange, with striped fruit and white flesh, is a very pretty sort. *Sustan*, *Dulcissima*, *Exquisite*, are varieties evidently from seed of the ordinary St. Michael's, differing slightly in foliage and form of fruit. There are two varieties of the Maltese, the Blood and the Oval, which is bloodless; the latter is a well-flavoured and large fruit, but is not better than the St. Michael's. The former should be grown in every Orange house; it is very compact in growth, produces an abundant crop of flowers, and is delicious in flavour, although slightly repulsive in appearance when cut. When first introduced in the Orange house, some years since, these Oranges did not bear fruit so freely as the varieties from the Azores; but possibly the plants have become accustomed to the climate, and they are now quite as fertile as the other varieties. My trees thrive vigorously and ripen their fruit in a house which is heated gently, and kept moist by syringing twice a day. There are also some sweet Oranges cultivated in France, of which trees could be readily introduced; but the first-named varieties seem to me most worthy of the careful cultivation to be given them in the tropical orchard-house.

Soil for Oranges.

The soil for potting should consist of the following: three parts sandy loam, from the surface of some pasture or healthy common, chopped up with its turf, and used with its lumps of turf about the size of large Walnuts, and its fine mould the result of chopping, all mixed together, and one part rotten manure at least a year old. To a bushel of this compost add a quarter of a peck of silver sand or any coarse siliceous sand (calcareous sand and road sand are injurious); and the mixture will do for all the fruit trees of the tropical orchard-house as well as for Oranges. Ferruginous soils evidently suit the Orange better than those of a calcareous nature, and should be selected. The soil of some parts of Sussex is well adapted, and if the climate would permit this county would be our large Orange grove. In some of the Orange plantations of Italy the soil is annually manured with old rags, which are found to contain a good deal of oil; I think, therefore, that cotton oil-cake, sold by manure merchants, will prove an excellent addition to the potting material; add also a few lumps of charcoal. In potting the Orange it is better to commence with a pot too small rather than too large, for, unlike the Peach or the Plum, it does not feed rapidly and at once fill the pots with roots. Thus a tree two or three years old may be potted in a 9-in. pot, suffered to remain for two years, and then removed to a 13-in. pot, in which it may remain (unless the house be very large and a large tree be wished for) six, seven, or ten years. A portion of the surface-soil should be annually removed in December, but not deeper than from 1 in. to 2 in., and the pots filled up with the above compost; and about the beginning of March a surface-dressing composed of horse droppings from the roads two-thirds, and one-third of kiln-dust thrown into a bed 1 ft. deep, and saturated with strong liquid manure from the cesspool, should be given. The French cultivators strew fresh sheep's manure on the surface; they also place their trees in a pure peat earth. Two other surface-dressings of the compost should be given—one in June, the other in the beginning of September. The trees will, of course, be placed on the hotbed, or plunged slightly 2 in. or 3 in. into the mould. I am not, however, an advocate for plunging to any extent, unless very rapid growth be required, for I find that trees in pots, standing on a bed of heated mould and rooting into it, make a healthier although a slower growth.

Treatment after the Fruit is Gathered.

As soon as the fruit is gathered, which ought to be by the end of February,* when foreign Oranges commence to be good, the trees

* I have departed from this rule by allowing fruits of the Maltese and St. Michael's to remain on the trees till June this present year (1865); they were then perfectly delicious.

should be lifted, and any roots that have made their way through the bottom of the pots should be cut off and surface-dressing given. Orange trees cultivated in the tropical orchard-house should have a part of the house to themselves, divided by a light glass partition, as they require and will bear more ventilation than other tropical fruit-bearing trees. Thus both borders of a small span-roofed house should be appropriated to them, the other part of the house being occupied with mixed trees and shrubs. Air can then be given to them by opening the sashes on one or both sides without interfering with trees and shrubs requiring less ventilation.

Orange trees, when grown constantly under glass, are liable to a black fungus on the upper surface of the leaves; this can only be removed with a sponge and warm water. They should be syringed with soft tepid water twice a day (at 9 a.m. and 5 p.m.) during the summer, and once a day in the morning, in sunny weather, in early spring and autumn; while the fruit is ripening in the winter, syringing should be discontinued. It is the custom to cultivate Orange trees in square boxes made of Oak. I am inclined, however, to recommend pots perforated at bottom, as usual with other pots. Slate pots are very neat and even ornamental; with three perforations they would doubtless answer very well. If wooden boxes be used, they should have bars at the bottom, to allow the roots to make their way into the hotbed and for drainage.

How to Form an Orange Grove.

There appears to be something bordering on romance when one talks of an Orange grove in England, and thinks of those unfruitful trees in tubs so common and so ugly; yet it is quite feasible. One day, ere long, Orange groves under glass, giving fruit, and flowers, and a perfume more agreeable than the dusty surface of the ground under a plantation of Orange trees in the countries where they are cultivated for their fruit, will be common enough in England when the method of making one is pointed out. There are two modes of forming a plantation of Orange trees under glass; one is simply to keep the temperature in winter from sinking below 30°; this may be done by having, in a large span-roofed house 24 ft. wide, five 4-in. hot-water pipes all round the house. In a house of this size, and thus heated, a central path 4 ft. wide or more should be formed, and the border on each side planted with Tangerine, St. Michael's, and any other kind of Orange that is not too robust and vigorous in its habit. Citrons, Lemons, and Shaddocks should not be mixed with Oranges in planting, but have a portion of the house devoted to them, or they will soon shade the more humble-growing kinds. Tangerine, St. Michael's, or other kinds of Oranges of moderate growth, may be planted about 5 ft. apart, and the borders in which they are planted, if not loamy or clayey, but light and sandy (for the Orange likes a stiff soil when growing *au naturel*), should have a dressing of stiff yellowish loam and rotten manure—two-thirds of the former to one of the latter, and 6 in. thick; this should be forked over and mixed with the soil to 18 in. in depth, and you will then have a border in which Orange trees will grow freely and bear abundantly.

A large span-roofed house, 100 ft. long and 24 ft. wide, would form a grove large enough for a most enjoyable promenade. There is another mode of forming an Orange grove under glass, more expensive and luxurious, by adopting "geothermal culture," and heating the borders as well as the air of the house. A house 24 ft. wide under this system would require four 4-in. hot-water pipes under each border (with rubble 4 in. deep over them), placed about 2 ft. under the surface, with a path in the centre of the house 5 ft. wide; each border may be from 9 ft. to 10 ft. wide; the pipes about 2 ft. apart. Besides these, there must be four 4-in. hot-water pipes to heat the air of the house in the ripening season. In a house thus heated those delicious (when first gathered) Maltese Blood Oranges may be grown, and the Pernambuco and other tropical varieties of the genus *Citrus*. Tangerine and St. Michael's Orange trees planted in these warm borders would ripen their fruit very early, and it would be sugary and rich.

I need scarcely add that an Orange grove may be formed in a small span-roofed house 14 ft. wide, with a path in the centre; and since writing the above directions for heating the borders, I have come to the conclusion that if the borders be raised 18 in. above the surface of the floor, either in the small or large houses, the heated air of the house will penetrate the soil so as to keep the trees in health and ripen their fruit.

There seems, indeed, no end to what can be done by Englishmen with the aid of artificial heat and glass. What a beautiful Vineyard under glass could be formed by such heated borders as I have described above! and how charming "to make a promenade," as our neighbours say, in such a place! No one but an enthusiast in gardening can imagine the pure quiet pleasure of taking a morning walk in the Orange-house, full of aromatic flowers and fruit, during the dreary months of December and until the end of March, and

plucking from the trees Oranges fully ripe. I have had much experience in the culture, and I may add in the eating, of fruit, and I can say with a firm conviction that I never enjoyed any kinds of fruit so much as I have Oranges of my own plucking in winter. The beauty and interest attached to an Orange-house, when the trees are kept in fine health, I can testify to in all sincerity. My house is an unfailling source of pleasure. A large house—a real Orange grove—would be a realisation of the gardens of the Hesperides. The trees ever green, almost ever blooming, seem to be an ever-giving source of delight to a mind alive to the beauties of Nature!

Insects.

The insects which infest Orange trees are two varieties of scale, and also the green aphid: the former are easily destroyed by methyated spirits of wine, applied with a painter's brush, and the latter by Quassia water—4 oz. of Quassia chips boiled ten minutes in a gallon of water. This is also an excellent preventive to scale, if the Orange trees be syringed with it once a week; it should be allowed to settle and be perfectly clear. If the leaves become black or dirty they should be sponged with warm water. Painting the stems with paraffin is certain destruction to scale, but care must be taken that it is applied only to the hard wood; the oil will injure young and tender shoots.

Pruning.

With regard to pruning fruit-bearing Orange trees very little is required. The shoots that are vigorous, and diverge from the round heads of the trees, should be shortened in summer by pinching them to half their length; and in winter, if the heads of the trees are too much crowded with small shoots, they should be thinned with a sharp knife.—RIVERS' "Orchard-house."

THE FRUIT CROPS IN KENT.

Mid-Kent.—It is feared that the fruit crop at Maidstone this year will be most unsatisfactory. Cherries will be thinner than they have been for some years; in fact, with few exceptions they are a complete failure. Pears and Plums are an irregular crop; the Plum trees generally are full of insects. Apples are also very uneven, though some kinds at present in places have a fair show. However, if the weather does not alter, and the nights become warmer, they will not hang. Gooseberries upon the whole are plentiful, though short at places. Black Currants in some parts are very uneven, and where there is a chance of a crop they are mostly covered with boneydew, and probably much of the fruit will drop. Red Currants promise well. Raspberries and Strawberries blossomed well, and with warm dry weather will be likely to grow a fair crop and pay well. Filberts and Cobs are plentiful at present, but it is too early to predict anything about the crop. In the parishes on the south side of Maidstone Gooseberries and Currants are under the average. Cherries quite a failure. Damsons bid fairly well. There are a few Morocco, Diamond, and Bush Plums, but very few of other sorts. Apples will be very few. Pears—best nearly a failure, common ones a fair crop. Nuts also bid fairly well, but it is too soon to give a decided report. West of Maidstone the fruit crop prospects are by no means satisfactory. Though there was a great show of blossom on all kinds of fruit trees but comparatively little of it "set" for fruit, and lately many of the just developed fruits have fallen off. Cherries will be scarce, notably the early sorts. Here and there, however, there are some Bigarreau trees that look like bearing a fair crop. Apples will be short. Caterpillars are busy among the leaves, and the small Apples are fast falling off. Damson trees, usually prolific, will give a poor return. The leaves of these are much blighted. Gooseberries are an indifferent crop; Warringtons will be very scarce; Lancashire Lads have borne the trials of the spring much better. Raspberries bid fair to be abundant. Of Currants, though there was a promise of a very large yield, it must be said that many of the black sorts have fallen off and are falling now, while the leaves of the bushes are in some cases shrivelled and blighted. The Red and White kinds look far more healthy, and will, it is thought, yield a plentiful supply of fruit. Cob and Filbert trees bloomed well, and the blossom set, but caterpillars have done considerable harm, so that this crop will not be so large as the growers had expected. Like the Hop plants, Beech, Lime, and other trees, many of the fruit trees are infested with various species of aphides. In the parishes of Boughton Monchelsea and Langley not only is there an absence of fruit, but the foliage generally has an unhealthy appearance, and there is a quantity of vermin. Cherries are very short. Apples below an average, and some kinds have almost entirely failed. Plums, with the exception of a few kinds, are short. Gooseberries good in the immediate neighbourhood, but bad in some parts. Nuts apparently good. In the Chatham district the fruit crop is exceedingly partial, but generally it is below a full average one. Apples promise a fair crop, and the

same may be said of Pears. Gooseberries are below the average, and a full crop is not expected. Cherries are only about half an average crop. Plums show a fair yield. In the district immediately surrounding the city of Rochester the fruit crop may be described as very patchy, with no prospects of anything like a large yield. At Southfleet and its district the fruit plantations show a large yield of Strawberries, although they are very backward. Raspberries also are a fair crop. Cherries are below an average. Plums and Pears are a good crop, and the same remarks apply to Apples. Gardeners in the Tunbridge district do not give a very good account of their grounds, neither Cherries, Gooseberries, nor Currants being plentiful. Apples have a tolerably good show, but high winds have cut the trees about very much, especially those in exposed situations. In several gardens the Cherry, Peach, and Plum trees are swarming with vermin.

West and Weald of Kent.—Taking the northern part of this district—viz., from Halstead towards London and Dartford, we get the following accounts:—Strawberries are a very heavy crop. Raspberries look well and bid fair for a good crop. Black Currants are only a moderate crop, but Red Currants are good. Gooseberries are rather an indifferent crop, the frosts having considerably affected them. This also applies to Cherries. In some places the growth of Apples, Damsons, and Plums will only be moderate, a fair yield being the exception. The crop of Filberts and Cobs too will be only moderate. The fruit crop in Cranbrook district will be in the aggregate by no means a luxuriant one so far as regards quantity. Cherries and Pears bloomed fully, and some sorts set well for fruit, but recently the trees generally have thrown out long shoots, and the fruit has fallen in large quantities. Apples, perhaps, will be a tolerable yield if all now goes on well, but the crop will be a patchy one. The same remark applies to Damsons and Plums; at places there are signs of a somewhat prolific yield, while at other places it is difficult to find more than a very few. The crop, however, will not be altogether unsatisfactory if the young fruit now on the trees should all grow and ripen. Strawberries are a great crop but injured by wet. Raspberries promise a bountiful supply. Currants and Gooseberries will be but a moderate yield.

East Kent.—Cherries excepted, fruit-growing is not so gigantically speculative in East Kent as in the western division of the county; but perhaps a failure is more widely felt, as most small occupiers and cottagers cultivate on a limited scale. Through a fine tract of land, extending from Greenstreet to Rainham, are to be found more Cherry orchards than, probably, in any other part of England; and there are several growers of this description of fruit whose average income from that source alone amounts to from £1000 to £1200 per annum. A uniformly heavy crop is not desirable, as it creates a "glut" in the market, and only low prices are at such times realised. These are not remunerative, owing to the cost of gathering the fruit and carriage to the markets of the metropolis. Indeed, it was but a few years ago that many growers were brought into debt by their salesmen on account of some of their consignments of Cherries not realising sufficient to meet the charges of carriage and commission. A few weeks since the appearance of the trees betokened another such minor calamity this season; but a marvellous change has "come o'er the spirit of the dream," and the crop of Cherries in East Kent will be very short this year. Plums have fared somewhat better. Apples promised a good yield. Pears are almost a total failure. In the neighbourhood of Ashford Apple trees promise well, and the same remark applies even more fully to Plums; but Pears are scanty, and Cherries very deficient. Gooseberries and Currants are an average crop. In the vicinity of Swarden and Bethersden the orchards look very badly; the Apple and Pear trees have an unkindly appearance; there will be but little fruit, and that very inferior. Cherries are nearly a failure. In Faversham and district the crop varies a good deal. Cherries are decidedly short. Here and there may be found a fortunate orchard, but generally the crop is light. Gooseberries are plentiful, Red Currants heavy, and Black Currants a fair crop. There was never a better show of Strawberry bloom, and Raspberries are also good, while wall fruit of all kinds is very scarce. The reports from Sittingbourne, which is the centre of an extensive fruit-growing district, are very unfavourable, and it is clear that the ingathering will not only be a late one but also a very small one. In many orchards, and among them some of the most celebrated Cherry plantations in the district, there are numbers of trees in which a ladder will not be placed. In one or two exceptional cases, however, the trees are well loaded with fruit. The crop of Apples and Pears will also be very short, and the way in which Plums are running off now makes it extremely improbable that there will be half an average crop. The only bright side to the picture is that there is likely to be quite an average crop of under fruit—Currants and Gooseberries.

Isle of Thanet.—The hopes raised by the abundance of blossom on our trees will not be realised, as the cold nights and ungenial days which have so long prevailed have not been favourable to the maturing of the fruit. There is a fair crop of Gooseberries and Cur-

rants, and Strawberries and Raspberries are plentiful. There is a spare crop of Apples, and but very few of the choice sorts of Pears; the hardy sorts hang well. Apricots and Peaches seem to be going out of cultivation as out-door wall fruit, Thanet soil or atmosphere not suiting them, and Plums of choice kinds are replacing them. Cherries, Plums, and other stone fruits will be scarce in the island.—*South-Eastern Gazette.*

THE INDOOR GARDEN.

THE ZEBRA-STRIPED COLAX. (COLAX JUGOSUS.)

At one of the meetings of the Royal Horticultural Society ten years ago I first made the acquaintance of a distinct and beautiful Orchid as a "buttonhole" flower. It was at a time when Orchids were in a manner new to me, and yet I knew enough of them to note the appearance of what was then a comparative stranger among them. I was so interested in a flower of such waxy purity as that under notice, relieved by rich purple velvet-like bars on its petals, that I timidly approached its owner and ventured to ask its name. "Colax

with charcoal nodules in lieu of crocks. When I state that the plant is even now "comparatively rare" I mean to say that although it may be seen in nearly all collections of cultivated Orchids, yet the flowers are so distinctly lovely that half-a-dozen specimens should be found where only one is now grown. The flowers are produced from January to May, and I should be really afraid to say how long they will keep fresh and beautiful if placed in a "specimen glass" after being cut, and they retain their beauty several weeks if left on the plant in the usual way. In common with one or two species of Phalenopsids and other Orchids, the sepals and petals of Colax are persistent, changing to a green colour after fertilisation has been effected. Our sketch was made from a fine variety which recently flowered in Messrs. Veitch's collection at Chelsea. F. W. B.

FILMY FERNS.*

THE principal genera which the group known as Filmy Ferns comprises are Hymenophyllum, Trichomanes, and Leptopteris, or Todea. The two former are very much alike both in habit of growth and delicacy of texture. Leptopteris is quite distinct, belonging to another tribe, the Osmundaceæ. Filmy Ferns have a very wide geo-

The Zebra-striped Colax

jugosus," said he, with a smile, "but what do you know about Orchids?" "Very little," I replied, "but I am fond of seeing them." "All right, my lad," was his encouraging answer, as he handed me his card; "then come to Wandsworth and see my collection there." I need scarcely add that the speaker was the late Mr. Sigismund Rucker, one of the most zealous of amateur Orchidists. Colax jugosus is even now comparatively rare, although from its unique character it deserves a place in all good gardens where intermediate or comparatively cool Orchids are grown. It attains 1 ft. or more in height, its green-nerved leaves being borne in pairs on smooth oblong pseudo-bulbs, from the base of which sheathing leaves and the two to three flowered spike are also produced. Lindley describes the flowers as "white, speckled with crimson," but the plants of it which I have seen in flower have invariably been of waxy whiteness, the petals and trowel-shaped lip barred or spotted with rich purplish-blue, and although its nearest allies are said to be the Maxillarias, it has many of the general characteristics of a Zygopetalum. It may be grown either in pots or in baskets, but perhaps pot culture has most points in its favour. The drainage must be good, for it cannot endure stagnation at the root. Chopped Sphagnum, peat and charcoal in nodules form a good compost for it, but the strongest plant I ever saw was grown in Sphagnum Moss and loam fibre, *i.e.* meadow or turfy loam, from which much of the earthy particles had been sifted—the pot itself having been drained

graphical distribution, being found in favourable positions nearly all over the globe. As an example of the wide range which these plants occupy, let us take the so-called Killarney Fern. The habitats given for it are in Europe, Ireland, Wales, and Spain; in Africa, Canaries, Madeira, Island of St. Thomas, Fernando Po, Angola, and Johannah Island; in Asia, Japan, Northern Hindostan, and Polynesian Islands; and in America from Alabama, Mexico, and the West Indian Islands, southward to Rio Janeiro. The majority of them, however, come from South America and New Zealand.

There are about 150 species of Hymenophyllum and Trichomanes, nearly equally divided into two halves; but I doubt if more than a third of this number are in cultivation at present. There are five species of Leptopteris or Todea known, all of which are in cultivation, their distribution being confined to New Zealand and Australia, and the islands of the Pacific Ocean. Three species only are found in Britain, *viz.* Hymenophyllum tunbridgense, H. unilaterale or Wilsoni, and Trichomanes radicans; they are, however, very rare, being found in a few special localities. Filmy Ferns differ from all others by the extremely delicate, and, in general, thin pellucid texture of their fronds. When in healthy condition they are the most elegant of Ferns. They love shade and moisture, many being epi-

* Read at the July meeting of the Scottish Horticultural Association by Mr. Robert Lindsay, Royal Botanic Garden, Edinburgh.

phytal and clothing trees, like Moss, or growing in shady ravines and caves.

With regard to their cultivation, with which we are principally concerned, they have somehow got the discredit of being very difficult to manage, a character which they do not by any means deserve. They are as easily grown as any other class of Ferns, provided some little attention is paid to the peculiar nature of the plants. The first and main point to be attended to in their cultivation, and without which it is useless to attempt to grow them, is to select a place where the atmosphere can be maintained almost at saturation point. This may be attained, in a measure, by means of a Wardian case, or even a bell-glass, a close-fitting frame inside a greenhouse, or, better still, if the means were at command, a small house for themselves. My idea of the kind of house required for these Ferns is a lean-to house, well sunk below the level of the ground, between 20 ft. and 30 ft. long by 8 ft. or 9 ft. wide, with a southern aspect, unheated, and with just sufficient head-room to stand in, the different kinds of Filmy Ferns being planted out on sloping banks amongst rockwork. Having got the right situation the rest is easily accomplished. The next important thing to attend to is shading; they all require to be heavily shaded from bright sunshine. Neglect of this for any length of time would, of course, be fatal to these Ferns. Still I would prefer some kind of shading that might be removed in very dull weather, and not a permanent shade, as they do not require to be grown in darkness, as is often imagined. The soil, whether they are grown in pots or planted out, should be of a free, porous nature. It should consist of good fibrous sandy peat, with lumps of sandstone and charcoal mixed freely through it, unless for *Todeas*, which will be greatly benefited by adding some good rich loam. Thorough drainage is most essential, as nothing hurts them more than over-doses of water. Although they require to be always moist, still it is not by drenching them with water that this should be effected. If they are in proper quarters a slight sprinkling daily will be the most that they will need. They should be potted moderately firm, as firm nearly as the rough nature of the soil will admit of, taking care not to injure the delicate rhizomes. While they grow very well in pots, the most natural way is to plant them out where they will have room to run and form large masses, which the stronger-growing kinds, like *Trichomanes radicans*, *Hymenophyllum demissum*, &c., would soon do. Several of the smaller-growing species, such as *Trichomanes trichoides*, *T. angustatum*, *Hymenophyllum tunbridgeense*, &c., do very well on blocks of wood, but this is only a matter of convenience or taste. As mentioned before, the great thing is to get the proper situation for them.

Almost the only one of the Filmy Ferns which has received that attention which from its great beauty it deserves, is the *Todea superba*, which is frequently seen in good condition and always much admired, and yet many of the species and varieties of *Trichomanes* and *Hymenophyllum* are equally fine and quite as easily grown. The great objection to their cultivation is one which cannot be altogether avoided—that is, they must be grown in shady nooks and corners where they cannot be well seen, but this would be entirely obviated by having a house for themselves.

With regard to their propagation, *Hymenophyllum* and *Trichomanes* may be increased by division. During spring they may be split up into little pieces and potted, without the slightest danger of losing a single bit, if carefully done. So far as I am aware the only Filmy Ferns that have been raised from spores are the *Todeas*, and it is well that they do so, as this section only forms single crowns, or very rarely more than one, so that they could not be increased otherwise. I have repeatedly tried to raise the different species of *Todeas* by sowing the spores in the ordinary way, and also by laying whole fronds down in flats prepared for them, but have as yet failed to raise a single plant; but if left alone they will sow themselves, and come up in thousands, covering the surfaces of the pots and walls with their peculiar glistening prothallia. *Todeas* are the only Filmy Ferns I have noticed come up in this way, although we frequently find different species of *Trichomanes* and *Hymenophyllum* with apparently fertile spores. But why do they not germinate? It has often struck me with regard to other plants that where we have plants which reproduce themselves naturally by suckers, runners, or in any other way, the fertility of their seed becomes diminished in proportion. Whether this is the right explanation as to why *Trichomanes* and *Hymenophyllum*, which run, forming many crowns, and in a measure propagate themselves, do not germinate from spores, while *Todea*, which has not that power, germinates so freely, I do not know, but it appears to me to be not unlikely.

A good many of the species of Filmy Ferns may be grown very successfully in rooms, either under bell-glasses or in Wardian cases. They are very well adapted for that purpose; the close confinement, which weakens and kills so many of the ordinary Ferns, seems to suit them admirably. I have seen them keep in good condition for years in a room, where the only attention given was merely that of

sprinkling the fronds with water once or twice a week. With regard to their hardiness, it is surprising the amount of cold they are able to bear. Although coming from warm climates, still we must bear in mind that it is only in heavily shaded woods, or on clefts of rocks at considerable elevations—which tend to lower the temperature of the localities—where they are found to a very great extent. From the nature of the fronds it is almost impossible that they could exist in a very hot climate. There may be a few which require some heat, but the majority will live and thrive better without the aid of fire-heat. In the spring of last year we had occasion, for want of room, to remove a number of Filmy Ferns. They were put into a small frame outside at the north side of a hedge, and all the protection they had otherwise was a single mat left on them, more to protect them from sun than from frost. They stood there all last winter, although frozen completely through for at least two months, and were very little the worse for it. The kinds put out into the frame were *Trichomanes radicans*, *reniforme*, *pyxidiferum*, and *angustatum*; *Hymenophyllum demissum*, *crispum*, *Wilsoni*, and *tunbridgeense*; *Todea superba*, *hymenophylloides*, and *Fraseri*. Only two out of this number were much injured, viz., *Trichomanes pyxidiferum* and *T. angustatum*. Notwithstanding this, the temperature ought always to be maintained rather above than below freezing point, covering with mats or such material being preferred to fire-heat. Air must be admitted but sparingly, indeed they will seldom require it at all unless during very dull weather. These are the principal points which must be attended to, but there are many little things, such as constant attention to cleanliness, and others which will readily suggest themselves to all who may attempt their cultivation, and which should by no means be neglected, as, however trifling they may appear, it is frequently by constant attention to little things that the successful cultivation of many of our plants to a great extent depends.

INDOOR PLANTS AT GUNNERSBURY HOUSE.

THE unique specimens of these that have been shown from Gunnersbury at the various exhibitions during the season afford ample proof that a skilful and unusual system of culture must be pursued in order to bring about such results. The houses consist of a lean-to range with the central portion raised for growing large plants. In the first compartment are grand specimens of *Crotons* comprising *C. Hookeri* of a size rarely met with and highly coloured; also *C. variegatum*, *pictum* forming huge masses several feet through. The largest plant which we have yet seen of *Alocasia Lowi* was growing here; it had leaves measuring 27 in. by 14 in. Handsome plants of *Cycas circinalis*, *Verschaffeltia splendida*, &c., were also growing here in vigorous health. A noteworthy fact is that no trace of any insect pest was visible, though the house was filled to overflowing with plants of all kinds in addition to a large plant of *Stephanotis floribunda* trained on the roof. Another point observable is that hot-heat is applied to the roots, but the pots are merely placed on stages, which raise the plants as near the light as possible, a point of great importance in the case of plants of this class. In an adjoining house was the finest batch of *Gloxinias* which we have seen for some time. The strain was superb, and the plants of unusual size, and a noteworthy fact is that they had been grown only in a greenhouse temperature, and when thus treated their value as decorative plants is much enhanced. Overhead were healthy Vines, affording thus proof that decorative plants and Grapes may be grown in the same house.

In the next house was a fine panful of *Davallia bullata* trained on a flat trellis, measuring fully 5 ft. across, and every frond as green as possible. Here were also fine examples of *Gymnogramma Wettenthaliana*, *Calomelanos*, and *peruviana*, *Gleichenia tabellata* and *dichotoma* (which is reputed to be difficult to manage), and *Adiantum Farleyense* 4 ft. across; also the delicate *A. gracillimum*, which is extremely elegant when seen in such a large mass. The larger plants, such as *Areca lutescens*, *Cycas revoluta*, *Dicksonia antarctica*, and others, are grown in the central division, which allows of their full development.

Another house in another part of the garden revealed other examples of high-class culture, such as *Davallia Mooreana*, *Maranta rosea pieta*, several kinds of *Coleus* nearly 3 ft. high and as much through, and a host of other plants in a smaller state. A single plant of *Harrison's Musk* measuring 3 ft. across shows what may be done even with plants of that kind. W. G.

Sarracenia flava as a Window Plant.—This would be an excellent plant to grow in a sunny window planted in a pan of loam, peat, and Sphagnum Moss, and covered with a tall bell glass.

I bought some imported rhizomes in April; they were planted out in the corner of a cold frame without any other protection and have made pitchers 1 ft. high, and this under full exposure to sun, rain, and wind. Plants that had previously been cultivated in a heated greenhouse would not have borne this rude system of culture; hence I recommend imported rhizomes which grow up freely, and the pitchers are then all equally fresh and bright in colour.—B.

POLYSTICHUM ARISTATUM VARIEGATUM.

AMONGST the more recent additions to our temperate house Ferns few can equal in decorative merit the one of which the accompanying is an illustration. It is a distinctly variegated form of *Lastrea aristata*, or to speak more correctly *Polystichum aristatum* (the latter being the oldest name, and the one under which it is found in most collections). In general appearance this species resembles an *Adiantum* of the *tetraphyllum* class; its fronds, which are somewhat triangular in outline, are from 12 in. to 18 in. long, and droop as regards the upper half. They have from two to four alternate pairs

Polystichum aristatum variegatum.

of pinnae, and a terminal one which is much the largest. The segments, which resemble small Holly leaves with awned teeth, are inserted with great regularity, and gradually diminish in size towards the points of the pinnae. The most striking feature of the plant, however, is the streak of yellow which runs down the centre of each pinna, occupying the inner half of each segment, and forming a fine contrast with the dark glossy green of the outer portion. It is a native of Japan, and is therefore well suited for conservatory decoration, or for planting out in a cool Fernery; it is also one of the few Ferns that are adapted by their coriaceous texture to withstand the dry atmosphere of dwelling rooms.

Polystichums of this class should be potted in a mixture of two parts light loam and two of sandy peat, and they also require to be rather firmer potted than most Ferns. Those with creeping rhizomes being surface-rooting do best in shallow pans, similar to the one here shown. They may be propagated freely from spores, the young plants from which make their appearance in from three to six months after the spores are sown; they may also be increased by division of the rhizomes. This section of the genus contains many plants remarkable for their bold and graceful habit, and also for the firm texture of their foliage. The following are the most desirable, viz.—

P. amabile.—A noble plant more erect in habit than *P. aristatum*, with fewer and larger segments; it attains the height of 3 ft. or 4 ft., and is a fine subject either for pot culture or for isolation in some prominent position in the temperate Fernery. It is a native of North India, Japan, and Formosa,

P. conifolium.—This is said to be an arborescent form of *P. aristatum*, but it is abundantly distinct. Its fronds are triangular in outline, and copiously cut into minute segments; their texture is very coriaceous, and they retain their freshness several days after being cut. It is a native of Sikkim Himalaya, and is rare in gardens.

P. capense.—A well-known Fern which, though frequently met with under the name of *P. coriaceum*, is one of the stoutest of the genus, and one which seems to thrive best on an elevated mound of turfy peat and loam, in which its rhizomes can creep freely near the surface. It is a native of tropical America, the Cape, and Australia; and though it flourishes in a stove temperature, it is equally at home in the conservatory or cool Fernery, where the temperature does not fall during the winter months below 35°.

P. flexum.—This species has a wide creeping rhizome similar to that of *P. capense*, to which it is closely allied; but the fronds are cut up into much finer segments, resembling those of some of the *Davallias*. It is of free growth, and makes an attractive cool-house plant. It is a native of Juan Fernandez.

P. laserpitiiifolium.—This is also known as *Lastrea Standishii* in gardens, and in character is quite different from all the preceding; as regards cutting of the segments it is one of the most elegant of the genus, the fronds are also of a bright light green, and spread horizontally. It is a native of Japan, and has proved quite hardy in this country. C. M.

TREATMENT OF ODONTOGLOSSUMS.

THESE plants are becoming popular with everybody, and it is generally recommended to keep them moist all the year round, and some even say they should be kept in a continually saturated condition when growing. That *Odontoglossums* have hitherto been grown fairly well by such treatment there can be no doubt; but the habit of the plant, and some knowledge of the experience of others in their culture, not to mention my own, suggests the inquiry whether such treatment is right. First of all, it would be very desirable to know under what conditions the plants thrive naturally. Do they grow in a spongy mass of sphagnum or peat, or on rocks, or on the ground, or on trees, or how? Is the atmosphere of the climate where the most of the species come from as dark and dull during summer as a glass house in England covered with a sheet, and is the summer temperature never above 60° or 65°—figures which I see recommended only last week in a contemporary? If that be so, then I venture to think that the climate of the North of Scotland must be too hot for them in ordinarily favourable summers, and that the South of England must be simply unendurable. In the article referred to it is stated that at one fine place, where *Odontoglossums* are well grown, the above temperature is never exceeded, if it can be kept down by the aid of shade and water. This being so, why not place the plants out of doors altogether, from spring till autumn at least? Putting aside the present season, the outdoor temperature is seldom under 60° during summer, and often much above it, and it therefore follows that the open air must be the best place for them. I have sought information on the above points from books and other sources, but cannot get it. On no subject are collectors more reticent than on that of the conditions under which the plants which they send home exist, and the consequence is great mortality amongst them. I hear that some tracts have been almost completely denuded of certain popular species of Orchids, which are likely by-and-by to become extinct in consequence.

As to treatment, it has always seemed, too, inexplicable to me why *Odontoglossums* should be an exception to all other species of Orchids that produce pseudo-bulbs, and which are generally subjected to a distinct period of rest, during which water is either partially or altogether withheld. In the case of the *Odontoglossum* one would think that it might be subjected to such treatment more safely than other species, because, while it has its plump bulbs to draw upon for nourishment, it is, moreover, treated at the resting period to an exceptionally low temperature, in which evaporation is reduced to a minimum. That the bulbs do afford nourishment to the plant under such circumstances is proved conclusively by the fact that imported plants stand a very trying drying process before being shipped, and afterwards grow. The bulbs shrivel much, but they fill up again when potted and placed in a growing temperature. It is true that when subjected to moist treatment all the year round the plants continue to grow constantly, some varieties, like *O. cirrhosum*, making two sets of bulbs in the season, and flowering as often, but it may be doubted if this is the habit of the plant under natural conditions.

Another reason why I am disposed to think we do not understand the treatment of this highly popular class of plants fully is the fact that it does not appear to suit one, at least, of the best of the genus, viz., *O. vexillarium*. It is well known, and nowhere better than in the trade, that this variety is very liable to "go off" in autumn and

when the plant is divided; numbers of fine plants have been lost in this way, and under the ablest cultivators. A specimen in a noted collection, and which produced not long since nearly 100 fine flowers, and was said to be about the finest plant of its kind in England, has died in this way; and we have from time to time heard of not a few other fine plants that have perished in a like manner—gone off at the neck. The first plant which we bought some years ago died in this way soon after we received it. Since then we have been more fortunate. It is worth while investigating the subject, and no doubt the record of experience of growers would be valuable. It is also doubtful if such a low temperature as 45° throughout the winter, and 55° or 60° maximum during the summer, is desirable or necessary. Here the best sorts grow well and strongly, and flower profusely, in a house which is kept from 5° to 10° less than the hot stove, and shade is not given except during bright sunshine. The exposure browns the foliage a little, just as it does that of a Pine-apple; but it is nothing the worse, but rather the better. *O. vexillarium* grows freely at the warmest end of the same house. I would recommend that during the season of growth the plants be kept just moist enough to keep the Sphagnum green and growing, with which the pots should always be surfaced, and that in winter sufficient water only to keep the same alive and fresh should be given, though probably less would do. C.

Lilies in Pots.—We saw a thriving batch of Lilies a few days ago in Mr. Peacock's garden at Hammersmith growing in pots plunged to the rim in a border skirting a wall with an eastern aspect. The kinds that were in best condition were *L. Washingtonianum* and its prettily tinted form (*L. purpureum*), *L. parvum*, *L. Hunholdti*, *L. pardalinum*, *L. Robinsoni*, *L. dalmaticum*, and several of the varieties of *L. elegans*, of which a very deep-coloured form—*atro-sanguineum*—was especially noteworthy. When Lilies are grown in this manner they are well adapted for greenhouse decoration, and this mode of management is better than growing them entirely under glass.

Town Window Gardening.—In a window—212, Vauxhall Bridge Road—a plant of the hybrid *Begonia Weltoniensis* is very fresh and bushy, the end of each growth being laden with pink buds. Elsewhere I have noted it doing well as a window plant, than which I feel sure no news will be more acceptable to its raiser, Col. Trevor Clarke. At 306 in the same road, the small-leaved Ivy forms a fine window blind, spreading elegantly in all directions. It is planted in large pots, and intermixed with it is a plant of *Virginian Creeper*. The Ivy is very fresh and attractive; the *Virginian Creeper* not so much so. Ivy is beautiful enough alone. There is much good town and window gardening in the locality, but these two examples are suggestive and should be seen.—B.

Mealy Bugs on the Roots of Auriculas.—In repotting a dozen Auriculas that have been blooming since last winter in a light, airy, cool greenhouse, I have just found several with mealy bugs on their roots. In some they had attacked the base of the stem, and in others they were all through the ball on the fine rootlets. The plants were in 5 in. pots, and the mealy bugs had evidently gained an entrance through holes made by earthworms. They were large lusty looking fellows that did not appear as though they had suffered from their underground habitation. The plants attacked were in a new house in which very few mealy bugs have ever been seen. Has any one known mealy bugs to attack the roots of plants, and how am I to proceed in such a case? I shook the earth out, killed the bugs, and washed the roots in soap suds and repotted.—DANIEL WITTER, 186, *L.imer Street, Denver, Colorado.*

THE BREAKING OF TULIPS AND PEAS.

THE remarks of "R. D." (p. 57) on Breeder Tulips in last week's GARDEN are very interesting, and I am induced to ask whether the seedling florist's Tulip, when fertilised solely by its own pollen, will require the usual period to break, or whether the seedlings are fixed from the period of their first flowering. The circumstances are somewhat different from those attending the Pea and the Sweet Pea, which usually take four years before becoming fixed; when the varieties or species are intercrossed, the intermediate state in the Pea not being confined to the colour of the flower, but the colour and shape of the seed and the pod, as well as the height and habit of the plant, vary, and the fixing period in the latter case does not apply to the original seedlings, in which, so far as I have observed, there is no variation. The Pea and Sweet Pea, however, are both annuals, or at least biennials, and in these plants the variation of the seedlings of the first and following generations the produce of a single intercross from those of the generations succeeding them without further intercrossing constitutes the want of fixity. In the Tulip it is the flower of the original seedling which varies. From an intercross between

Pea Supreme, a round, blue-seeded variety, with weak green pods and a purple-flowered, purple-podded variety with greyish-white seeds, I selected a seedling of the second generation with black seeds, purple pods, and purple flowers, and on sowing the seeds this year some of the seedlings have produced white flowers and purplish-tinted pods, and others have white flowers and green pods, but without the usual purple stain in the axils of the leaves, so characteristic of the purple-flowered *Pisum arvense*; others, again, have purple flowers and green pods, but the majority purple flowers and purple pods. To further test the extent of variation in the Pea, I have this year *inter alia* intercrossed the white-podded round white-seeded Pea *sans parchemin* with this purple-podded Pea, and also with blue and white wrinkled varieties, and shall anxiously watch the results, as the whole subject is deeply interesting, and, although the analogy is not complete, it would be instructive to ascertain whether in the Tulip, breeders are produced where no intercrossing takes place, and the seedlings are from a self-fertilised flower only. T. LANTON.

Bedford.

NOTES OF THE WEEK.

The Twining Brodiaea (*B. volubilis*).—This is one of the most remarkable of cultivated bulbous plants on account of the twining flower stem, which is about the size of a crow quill, and which in its native habitat attains from 4 ft. to 12 ft. long, terminated by a dense cluster of about twenty blossoms, which are $\frac{1}{2}$ in. long and of a deep rose tint. The leaves are few in number and from 1 ft. to 2 ft. in length. It inhabits rocky situations in the valley of the Sacramento and other places of California. It may now be seen in flower at Kew, though the specimen is small compared with the size which it attains in a wild state. We have also received some flowers of this Brodiaea from Mr. Thompson, of Ipswich, who informs us that he has raised his stock from seeds, as few, if any, bulbs are imported into this country.

Senecio japonicus (syn. *Erythrochæte palmatifida*).—This little-known Groundsel is one of the handsomest of the composites now in flower at Kew. It is of bold habit, growing about 5 ft. high, with leaves nearly 1 ft. across, divided into about nine divisions. The flower stems are slightly branched, and the flower heads are about 3 in. across, with the outer narrow florets of a rich orange colour. It is a native of Japan, but perfectly hardy at Kew. It is a moisture-loving plant, therefore the present season has been very favourable for its growth. It should be grown in a rich and moderately stiff loamy soil, and should be copiously watered during summer.

Odontoglossum vexillarium at Gunnersbury Park.—One of the finest examples in cultivation of this lovely Orchid is now in flower here. It measures over 3 ft. across, and has twenty-six flower stems, each of which bears from four to six flowers, making altogether 139 blossoms. It is now making several new healthy growths, which will probably develop an even greater number of flowers next season. In the same house we noticed some vigorous flowering plants of the beautiful *Epidendrum vitellinum majus*, also *Odontoglossum Alexandræ* in rich variety and fine specimens, amongst which was the variety *Rothschildi*, which has the flowers copiously spotted on all the divisions. The singular *Eriopsis biloba*, with its racemes of rich chocolate flowers, was also in flower, though not showy enough to be grown, except in large collections.

Gunnera scabra.—The huge specimen of this handsome Chilean plant in the herbaceous ground at Kew has now attained its full development for the season. It is fully 10 ft. across, and its gigantic Rhubarb-like leaves are nearly a yard square and rise from 6 ft. to 8 ft. high. It is somewhat strange that this plant is so seldom planted in private gardens or in our public parks, squares, &c., for no other hardy plant has a nobler or more tropical aspect, and moreover, it is very easy to cultivate. It requires a well-drained position, rich soil to grow in, and abundant waterings during the growing season.

Rock Plants at Chiswick.—The rockery is now gay with alpine and other plants of more or less rarity and interest. Of these the pretty creeping Androsace, of the Himalayas (*A. lanuginosa*), is conspicuous on account of its long trailing branches covered with silky foliage terminated by clusters of Verbena-like blossoms of a pinkish-mauve tint with a distinct yellow eye. Another interesting Indian plant is the wedge-leaved *Potentilla* (*P. cuneata*), which grows in a dense mass, and produces deep green three-toothed leaves, and bears many clear yellow blossoms of about the size of a shilling. A large tuft of the Larch-leaved *Arenaria* (*A. loricifolia*) reminds one of some of the Saxifragas which are now just shedding their flowers; it is a capital plant for the rockwork, as it grows rapidly and lasts a considerable time in perfection. Various smaller growing kinds of Hare-

bell are in full flower, the best being *Campanula muralis*, *C. garganica*, and its hairy-leaved variety *hirsuta*. The pretty *Saxifraga Hirculus*, an indigenous species, found in a few northern localities and growing only in wet places, thrives admirably here in a rather dry part of the rockery, and is now furnished with several large bright yellow and profusely spotted blossoms. *Pentstemon Cobaea* is one of the handsomest of the cultivated kinds, and at Chiswick it thrives well; both on the rockery and in the open border there are plants in full flower, which are about 2 in. long and proportionately broad; the colour is a delicate mauve with heavy pencillings of a deeper colour in the throat. Few rock plants are prettier than the round-leaved Thyme (*Thymus rotundifolius*), which is apparently a variety of *T. Serpyllum*; it forms spreading dense tufts covered with clusters of small purplish flowers. Flowering plants of tuberous-rooted *Begonias* also enliven the rockery, several of which have withstood the past winter quite uninjured.

Royal Horticultural Gardens, South Kensington.

—In answer to Mr. R. Yorke, the Chancellor of the Exchequer stated the other day that plans for the utilisation of the ground now occupied by the gardens of the Royal Horticultural Society at South Kensington were under the consideration of Her Majesty's Commissioners of 1851, and that the decision arrived at would, no doubt, be in accordance with the original design of employing the estate for the promotion of science and art.

Geranium polyanthes.—A pretty plant bearing this name is now in flower on the rockery at Chiswick. It grows about 1 ft. high, and has roundish leaves similar to those of *G. rotundifolium*. Its flowers are arranged in dense clusters, and much resemble in size, colour, and form those of Bowie's *Oxalis* (*O. Bowieana*). Such a distinct plant is well worth including in a collection, though it is not so showy as several other kinds. We can find no reference to the species, though it was contributed to the collection by the late Mr. McNab.

Milla longipes.—Flowers of this new bulbous plant were exhibited by Mr. Elwes at South Kensington on Tuesday last from plants raised from seeds two years ago. It is more remarkable for the large number of blooms borne in each umbel than for their bright colour. They measure about 1 in. across; their inner surface is of a glossy whiteness, and they are heavily feathered on the outside with a livid purple tint. It is, like its pretty congener *M. laxa*, a native of California.

Rainer's Harebell (*Campanula Raineri*).—Of the many kinds of Harebells now in flower at Kew, perhaps none are so attractive as this charming species. It is very dwarf in growth, being not more than 1½ in. high, but the flowers are unusually large, compared with the size of the plant. They much resemble those of *C. turbinata* in size and colour, though just a trifle smaller. It is growing in the open border in company with the other kinds, and is evidently thriving as well, or even better, than those planted on a rockery.

Heart-leaved Seakale (*Crambe cordifolia*).—One of the most striking plants in Battersea Park at the present time is this handsome Caucasian Seakale. It is a hardy perennial growing about 5 ft. high, with large bold foliage, and flower stems much branched, forming a large roundish head, which at this season is covered with numerous white blossoms. It is a capital plant for the wild garden and such like places, or as isolated specimens on lawns, &c.

Escallonia pterocladon.—This is now beautifully in flower in Mr. Gumbleton's garden at Belgrove, near Queenstown, where it grows with unusual vigour, forming a tree 35 ft. in height in about nine years. When of this size it has a fine appearance, especially when covered as it now is from top to bottom with minute white blossoms. In such localities it is a capital shrub for training against a wall.

Disa grandiflora.—Several varieties of this *Disa* are now in bloom in quite small pans in the Pine-apple Nursery. They have been grown in a house where they have been frozen quite hard during the winter. The stronger growths are encouraged to make flower shoots, and the weaker ones are restricted or removed and potted for flowering next year.

Hardy Aquatics at Kew.—Owing to the increase in the number of hardy aquatic plants at Kew, a properly constructed tank for their accommodation has been a pressing want for some years. This has at last been supplied. The new tank is about 80 ft. long and 24 ft. in width, the outside walls of which are of brick raised about 2½ ft. above the ordinary level. The bottom is puddled with a layer of clay about 15 in. in thickness, upon which is a layer of concrete and cement about 9 in. in depth. The inside surfaces of the walls are also cemented, so as to make the tank perfectly watertight. Several narrow walls intersect the tank, thus forming it into square compartments, in which are planted the more robust-growing plants, and a shelf-like portion is devoted to bog and marsh plants

in pots. A constant flow of water, so essential to the well-being of the majority of water plants, is furnished. Though the planting has not been completed for more than a week or so, several are thriving vigorously, amongst which is the new rose-coloured Water Lily, which is now in flower. The pretty little *Aponogeton spatulaceum*, too, is in flower, as well as several other interesting plants. One objection to this tank is the height of the water above the path and the unnatural angle from which the plants are viewed, which considerably mars their effect; whereas under natural conditions the eye invariably looks down upon the plants, the whole of which may be seen at a glance.

Angræcum Ellisi and **A. citratum.**—Messrs. Veitch have recently had a small importation of these very rare species of *Angræcum*. A few of the plants which we recently saw at their establishment were in remarkably good condition, and had every appearance of becoming established and in a thriving state in a comparatively short space of time.—P. G.

Bollea cœlestis.—A specimen of this which is now in bloom in the York Nurseries far surpasses in quality any variety hitherto flowered there. It reaches the highest ideal of the species in size, form, and in the intensely deep blue-purple of its blossoms. Some eight or nine flowers are expanded at once.

Ixias.—Few flowering plants are more beautiful than these or more diverse as regards colour, and yet they are seldom met with in gardens. Many imagine that they are difficult to manage; but that is by no means the case. They have flowered most profusely this year in Mr. Barr's grounds at Tooting, where all the protection they had last winter, severe though it was, was a covering of Fern.

National Carnation and Picotee Society.—The exhibition of the southern section of this Society will be held at South Kensington in conjunction with the meeting of the Royal Horticultural Society, on Tuesday, the 12th of next month.

Corn Exchange Rose Show.—This exhibition, which is annually held in Mark Lane for the benefit of the Corn Exchange Benevolent Society, this year realised over £25 after payment of all expenses.

ROSES.

A ROSE SHOW IN AUGUST.

UNFORTUNATELY all the Rose shows of the season have been too early. The shows have been held, but the Roses, shy and coy, and ill to please at times, have refused to come. With the exception of Mr. Baker's Roses at Norwich, but few perfect flowers have yet been seen this year. They are coming, but have not yet come. The "maidens" especially have not yet put in an appearance. Huge buds, like cricket balls, weigh down shoots like fishing rods, and refuse to open in these dripping days and nights. A good many, however, go on filling, filling, so that when they do open they will be a sight to see. For this reason, and also to mark the peculiar character of the season, it might surely be worth while to make a special effort to get up a great popular Rose show in August. The time is short, but that depends on how long it goes on raining. Looking at the present downpour, which has lasted for about forty-eight hours, it seems as if the rain, like Tennyson's "Brook," might flow on and on for ever. But few of the Rosebuds, however, have rotted; they have only waited. Hence, possibly the middle of August might not be too late for a great Rose show in the metropolis. It may be too late for the upper classes to see it, but that matters little; they have their Roses every day in the year and all the year round. Besides, it is not the upper classes, but the toiling millions that enjoy the sight of Roses most, and that would make a large show in August pay. What say the growers, large and small, to a great show in say, the Agricultural Hall, Islington, as soon as possible? Such Roses as have never yet been seen in August, or perhaps in other month would be forthcoming; and if Roses are worth waiting for they might also be worth showing so late. By breaking fresh ground, a new impetus would also probably be given to Rose culture, so that commercially the show would prove a success: for the sight of such Roses as could be shown in a fortnight or three weeks' time could hardly fail to stir the enthusiasm of the thousands of the working classes who would flock to see them. Financially, the show, if properly managed, would probably succeed, and if not it would be worth some considerable sacrifice of time and money to place the best Roses before the masses; for of all the modern means for their higher education, culture, and refinement, I should give about the highest place to the culture of flowers. For this purpose I would confidently offer the advice to try Roses. I have noticed their power around Nottingham, where they have become bonds of union and centres of sweetness and light to thou-

sands of toiling men and struggling women. A great exhibition of Roses in some such place as the Agricultural Hall might not only prove one of the most notable events of a season unique in its eccentricities, but prove a powerful factor in elevating the tastes and refining the pursuits of the working classes. D. T. FISH.

MR. BAKER'S ROSES AT NORWICH.

THESE were so perfect—without spot or flaw—in a season when the paucity of sunshine, the redundancy of rain, and the prevalence of wind have so retarded and tarnished the finest Roses, that a few words on the secrets, if any, of their production could hardly fail to possess special interest for the readers of THE GARDEN. Of course Exeter is a far more genial clime than that of East Anglia: but these Roses, such as the perfect dozen—the finest ever seen probably—of Charles Lefebvre and others, looked as if no winds had ever ventured to play around their petals nor any rain ever moistened them. Were they the first products of dwarf “maidens,” as generally reported at Norwich, and each flower grown under portable glass lights or frames? Or were they nourished into size, moulded into form, and coloured, finished, and perfumed so perfectly by some specially rich food? Or were these matchless flowers the legitimate outcome of careful culture? Perhaps Mr. Baker himself may be generous enough to enlighten your readers. Another point of much interest is how Roses in the latest stages of size and perfection could be safely transported from Exeter to Norwich without one of them opening its eye. I know not how the Roses looked on the second day of the show, but on the first they were perfect, though, as a capital grower remarked, “on their last legs.” If, in fact, they had a fault it was that they were too large and a little too old. Still not one of them showed its heart nor gave any indication of falling to pieces. Their texture and build were also something unique. One of our finest growers for sale, who was thoroughly beaten by Mr. Baker, declared that a long journey would be well undertaken to see such Roses at the end of it, and generously declared that he had never seen such flowers before. This set me thinking whether Mr. Baker would resent the intrusion of a few enthusiasts or writers like myself to his house of prize Roses, with the express intention of worming out and revealing his Rose secrets, or will he prefer telling us all about them himself? Assuredly he has erected a new and a higher standard in regard to the five vital points of size, form, texture, colour, and freshness of exhibition Roses to which most of us are anxious to attain. I therefore appeal to him to help us with his counsel and guidance through your pages. D. T. FISH.

VICTORIA PARK.

THOUGH the present season has been so detrimental to tender bedding plants which in this park generally form so important a feature, it has nevertheless been highly conducive to the luxuriant growth of hardy perennials, of which there is an extensive collection here, placed as a foreground to a shrubbery nearly a mile in length. This border is now gay with such showy plants as Larkspurs, Monkshoods, Harebells, Irises, Lilies, and a host of other fine border plants, which, being planted indiscriminately, afford a striking contrast to the geometrical designs of the surrounding parterres. Such a border as this affords a vast amount of interest throughout the year, and is highly appreciated, and it gives moreover very little trouble. Seldom at this season have we seen trees and shrubs wear such a verdant hue as they do now, and here, where so much has been done with regard to careful planting and judicious selection, the fact is more apparent than in most places. Victoria Park abounds in handsome specimens of Hollies of a size rarely met with, and in such rich variety too as to show that the Holly is one of the best shrubs for town planting. Various kinds of Elders also thrive admirably here; the golden-leaved variety especially stands out in bold relief amidst the deep green of the other shrubs. The cut-leaved form (*Sambucus laciniata*) is a very graceful Elder, and one which should be in every shrubbery; as should also be its variegated form. The latter does not however always retain its variegated character if planted in the shade, or if it receives too liberal treatment. The golden-leaved Catalpa is another beautiful shrub which is very conspicuous here, and is even preferable to the Elder in some situations. There are but few trees or shrubs in flower at present, though a few weeks ago they were gay enough, for the plantations and shrubberies have been planted with due regard to a copious admixture of those that produce a showy effect during spring and early summer. One shrub, however, deserves notice as it is now very pretty, viz., *Cytisus nigricans*; though an old introduction it is still unsurpassed as a late-flowering kind. It produces its pendulous racemes of yellow blossoms in graceful profusion similar to the Laburnum, though it never attains such a large size.

The picturesque glimpses to be obtained here and there from different positions round the lake are considerably enhanced by huge masses of such plants as the Burdock, the Water Dock (*Rumex Hydro-lapathum*), Common Flag, and various kinds of *Lychnis* and other plants which revel in native beauty round the margins of the islets. This semi-wild kind of gardening is evidently encouraged by Mr. McIntyre, and it is certainly not the least of the many interesting features to be met with in this fine park. Several examples of the Weeping Elm with branches dipping into the water are particularly noteworthy, and cannot be too highly recommended for planting in like situations or anywhere so long as the position is moist. It is much to be regretted that almost every kind of Conifer utterly refuses to grow here, owing no doubt to the impure state of the atmosphere. The specimens that still survive are but miserable examples of what they ought to be. W. G.

PLATE CXC.

IRIS DARIUS AND I. FLORENTINA VAR.

Drawn by the late NOEL HUMPHREYS.

FEW border flowers are greater favourites than Irises, the majority of which grown in gardens are collectively called German or Bearded Irises, in contradistinction to the English (*Xiphium latifolium*) or the Spanish Iris (*X. vulgare*), which have bulbous root-stocks. Botanically considered, there are comparatively very few of the German Irises derived from the true *I. germanica*, as there seems but little variation in the colour of their blossoms. The species which appear to have yielded the greater number of the varieties are *I. lurida*, *squalens*, *neglecta*, *sambucina*, *aphylla*, *flavescens*, and *variegata*. These are chiefly of tall growth. The dwarfier-growing kinds have probably sprung from *I. pumila*, *lutescens*, *biflora*, *Chamaeiris*, &c. A descriptive list of the principal varieties of these will be found at p. 195, Vol. VI., of THE GARDEN.

The variety of the Florentine Iris represented in our plate was sent to us by Mr. Ewbank; its blossoms are bluer than the type. This is nearly related to the new Cashmere Iris (*I. cashmeriana*), recently named by Mr. Baker, though it is later in flowering and more fragrant. Another section of Iris that has not yet been grown in gardens so extensively as it ought to be consists of the Beardless kinds, which comprise such as *I. virginica*, *versicolor*, *sibirica*, *spuria*, *Kaempferi*, and many others of rare beauty. The culture of these is of the simplest kind; indeed, they grow well in any ordinary good garden soil. W. G.

Sempervivum Pomelli.—Mr. Jenkins (p. 58) seems to think that I am wrong in supposing the plant at St. Alban's Court to be *S. Pomelli*, and it is possible I may be. It was the coloured tips that induced me to form the opinion which I did. *S. Pomelli* belongs to the *barbatulum* or bearded group, and must be distinct from the arachnoid or cobweb section. Nevertheless Mr. Jenkins exhibited at Manchester a plant as *S. Pomelli* without a tinge of colour and densely tomentose or cobwebbed, whereas *S. Pomelli* is only bearded. Mr. Jenkins's plant I pronounced to be *S. Lagerri*, which to me it very closely resembled; and if I am wrong in a guess at *S. Pomelli*, Mr. Jenkins must be equally so as regards the plant which he exhibited.—T. WILLIAMS, *Ormskirck*.

Irises amongst *Salisburia adiantifolia*.—As a rule most plants, owing to the absence of sunshine, are deficient as regards bloom, and instead of admiring the flowers of rock and Alpine plants we have to destroy slugs and trim in rampant growths caused by the continued rainy weather. Roses and Campanulas especially are good, and would produce fine flowers if favourable weather set in. One class of Irises, however, deserves mention. Last autumn I dibbled in a quantity of *Iris hispanica* amongst some *Salisburia adiantifolia* on a bed 9 ft. by 6 ft.; the latter are young plants about from 18 in. to 2 ft. high. The Irises have just overtopped them with their blooms, which are large, of fine form, and of almost every colour, except red or scarlet. The effect of this mixture is exceedingly good, the pretty foliaged *Salisburia* furnishing the otherwise scanty undergrowth of the Iris; besides, the flowers have such substance as to withstand the rain, and for a good many days they look none the worse for it. I am sorry to say that *Lewisia rediviva*, of which I spoke a few weeks ago as doing so well, suddenly became flabby and did not fully expand its blooms. I hear that it has this fault as a rule. I should be glad to be favoured with the particulars of treatment from any one who has it in good health, for it must be a gem when well grown. Thanks to Mr. Williams for his correction (p. 32); instead of *Arenaria balearica* my description should have been applied to *A. maritima* (p. 8).—JOHN WOOD, *Woodville, Kirkstall*.

GARDENING FOR THE WEEK.

Stove.

In ordinary seasons through this and the ensuing month it is usual in the case of many growers to dispense altogether with fire-heat, which may for the most part be done, provided sun-heat is carefully economised through closing the ventilators sufficiently early in the afternoons; but the weather is so different this summer from that which we generally get that, where no fire-heat has been used, the plants are anything but in a satisfactory condition, not alone as regards their backwardness in blooming, but as respects the soft, immature state of the wood. To fully remedy this, even if the weather is brighter during the ensuing month, it will be well to at once give artificial warmth, which will permit of more air being admitted. Another matter of importance in such seasons as this is to reduce the atmospheric moisture considerably, less being needed in damp, cloudy weather, like that which has prevailed all through the spring and summer, than is required when we get the ordinary amount of sunshine with a correspondingly drier condition of the air. The conclusion at which I have long arrived with reference to the cultivation of plants under glass, especially those that require the almost continuous use of fire-heat, is that there is no worse mistake committed in their management than the use of more shading than is absolutely necessary, particularly when it is of an immovable description; I have before alluded to this, but it is long since we had a summer that so fully exemplified the evil arising from it as the present. In houses where the glass is smeared with the usual compositions employed for the purpose, and especially where the material is laid on thickly, the plants have now through the whole of the months wherein the greater portion of the season's growth is made been under the influence of semi-darkness, a condition still further aggravated when the structures are of a heavy character, and the plants a considerable distance from the roof. Where this is so, I have seen in some places such plants as *Allamandas* and *Dipladenias* show little disposition to flower, and altogether in an unsatisfactory state. It is, therefore, obviously necessary to dispense with shading from this time forward as far as possible, with a view to ripening the wood before the days get short.

Gardenias struck from cuttings this spring, or plants that have been cut back with a view to keep them within limited bounds, must during the next month be encouraged to complete their growth, as after that time the treatment should be such as will tend to solidify the wood rather than increase its amount. With these the disposition that frequently exists in the flower-buds to fall off when forced during the winter and spring is, I feel convinced, attributable to an immature state of the wood more than to any other cause.

Climbers.—Plants of this description grown on the roof or rafters require constant attention to keep them within reasonable bounds; but it is necessary to use the knife with judgment, indiscriminate shortening, especially with free-growing subjects, in most cases having the effect of limiting their blooming capabilities. The right way to proceed where they are growing so as to encroach upon each other, or to too much diminish the light in the case of plants beneath them, is to remove a sufficient number of the shoots altogether, selecting those least likely to give a succession of bloom. This is a work of absolute necessity, for however effective for the time being a free uninterfered-with growth may be, it is no compensation for the flowerless state to which subjects grown under it will be reduced. Between these roof climbers and the general occupants of the house there must always be a compromise, otherwise the result is that the stove virtually exists for the climbers, as nothing under them can grow to a condition fit for the purpose for which it was intended. The treatment recommended especially applies to such free-growing plants as *Allamandas*, *Clerodendrons*, *Aristolochias*, *Bougainvilleas*, *Ipomæas*, and the strong-growing *Thunbergias*. *Stephanotis*, *Hoyas*, *Dipladenias*, *Combretums*, and others of a like character are not so rampant in growth as to admit of much cutting without proportionately diminishing the amount of flower which they would otherwise produce. In the case of climbers or twiners grown for their effective foliage only, there need be no further hesitation as to using the knife than to avoid giving them a too closely trimmed-in appearance, which can always be avoided by leaving a few of the shoots in a pendent position.

Winter-flowering Stove Plants.—The same conditions as regards absence of sun and low temperature that have affected stove plants generally hold good more forcibly in the case of ordinary winter blooming subjects which may be said to comprise *Sericographis Ghiesbreghtii*, *Thyrsacanthus rutilans*, *Poinsettias*, *Lasian-dras*, *Euphorbia jaquinæflora*, *Eranthemum pulchellum*, and *Plum-lago rosea*. Unless the plants were struck early, and were unusually forward in the spring, they will now be both small and full of soft

growth; the ordinary summer treatment under which such plants generally succeed well in pits with little or no fire-heat is not sufficient this season to get them up to a large enough size and permit of their receiving sufficient air to keep the growth of that short stout character essential to free flowering. It is therefore advisable to apply heat at once where this has not all along been used.

Bouvardias.—These indispensable winter-blooming plants should now receive every assistance to enable them to acquire size and strength, for on this almost wholly depends the amount of flower which they will produce. One stout plant with strong shoots, which is capable of bearing a second and third crop of flowers after the first have been cut, will furnish more bloom through the winter than three weakly ones. In the case of cut-back examples that have bloomed previously, there need be no difficulty in getting them sufficiently large before autumn, but with those that have been propagated from root or shoot cuttings during the winter or spring the case is very different, and unless means are immediately taken to encourage growth in every available way, the time that admits of it will be past whilst yet the plants are so small, as to be of very little use during the coming winter. With them it is simply a question of enough artificial warmth, and should the weather continue cool and sunless, it will be necessary to at once employ as much fire-heat as will insure brisk growth, and permit of sufficient air being admitted; but these plants, if in a light position, will do with less ventilation than those subjects that are of a less free-flowering disposition. For the same reason they may be kept growing later in the season, as they do not require such a lengthened ripening process as those plants that are less inclined to bloom almost continuously.

Shrubby Clerodendrons.—For general decorative purposes these are most useful grown and flowered in 8-in. or 10-in. pots, discarding the plants afterwards; this, of course, necessitates their yearly propagation, either by means of seeds or cuttings; the present is the best time for striking them, as, if put in earlier, they get larger before winter than is needful, occupying more room than they ought to do, and if struck late they do not get sufficiently strong to admit of the full development of which they are capable. The small shoots pushed from the stems after the removal of the heads of flower make good cuttings if treated in the ordinary way in small pots with sandy peat or loam and heat, shade, and moisture. Those possessing a stove, however small, and who appreciate one of the most exquisitely-scented flowers in existence, will find the old *Clerodendron fragrans* surpassed by none; it is a comparatively small-leaved plant, with spare, erect growth, occupying little room, and should be cut down within a few inches of the collar each autumn; thus treated it can be kept small in size for a number of years. The usual stove treatment suits it and the others.

Orchids.

Aerides and Saccalabiums.—Any remaining plants of these that have flowered late, and that require re-potting, should at once be attended to; but, with them as with other Orchids, blooming generally exhausts them, causing them to shrivel somewhat, and on no account should they be subjected to the more or less root-disturbance inseparable from re-potting until sufficient time has elapsed after blooming for the plants to regain their wonted plump condition.

Phalænopsids.—These more than most Orchids should never be disturbed unless there is an unavoidable necessity for moving them; the tenacity with which their roots cling to everything with which they come in contact, and the difficulty experienced in moving them without serious mutilation, at once show the weakening influence that removal has upon them. Yet when the blocks, baskets, or whatever they are grown in are of a perishable character, such as when made of wood, the time comes when decay reduces them to a spongy rotten mass, so soft that the roots can penetrate it; and when this takes place they ultimately decay from the effects of contact with the saturated rotten material. Hence it is necessary to move them before they are reduced to this condition; inattention to this has brought numbers of fine specimens of these beautiful plants to very small dimensions, from which they take years to recover. Whatever wood is employed in the construction of the blocks or baskets it should be of the most durable character; the plants must be well secured until the roots have time to establish themselves. Use only a thin stratum of Sphagnum over them; a considerable body of this material is not necessary, and when present in quantity it only hastens the destruction of the wood. I have found *Phalænopsids* do well tied with wire to the bottom of an inverted flower pot with Sphagnum over their roots similarly to when on a block of wood. The inverted pot should be placed in another of larger size, half full of drainage material, and the remaining space should be filled up with charcoal and a little Sphagnum. In this way there is nothing that will rot except the Sphagnum, which when too much decomposed can be removed, syringing all the

remains clean out after the rest is picked away by hand, replacing it with fresh material.

Dendrobiums.—Such plants of the different species as bloomed early, and have made a correspondingly early growth, will now be somewhat at rest. This will be especially the case with *D. nobile*, *D. chrysanthum*, and others that are used in numbers in many places for decorative purposes, as also the earliest-bloomed examples of *D. Wardianum* and allied species. These, when their young growths are approaching a matured condition, should be gradually inured to a drier state at the roots, yet water should not be withheld so much as to suddenly stop the pseudo-bulbs from attaining that plump character which is essential to the free production of bloom. The majority of these plants will now be in full growth, and must be liberally supplied with moisture both at the root and in the atmosphere. Unless in the case of a few exceptional species, there is no way in which they succeed so well as grown in baskets hung up close to the roof; not only do they grow better in that way, but the stout matured condition of the pseudo-bulbs always enables them to produce a greater quantity of flower than when grown in pots in the ordinary manner. Thus treated they have also a more natural and pleasing appearance either when growing or when in bloom. Even the old partially-erect-growing *D. nobile* looks best in this way, the ordinary forms assuming a half drooping habit.

Pleiones.—These beautiful little winter-flowering plants will now be fast forming their bulbs; they are water-loving subjects, and must be kept well moistened at the roots.

Cœlogyne cristata.—In many places where no regular collection of Orchids is attempted, but where a few of the best winter-flowering kinds are required, this fine old plant is indispensable, and should be grown in quantity so as to have it in succession; it is also a plant that must have plenty of water during the growing season, as, like all others found indigenous at considerable altitudes where they are all but continuously in a half saturated condition, it cannot endure anything approaching dryness at the roots whilst the growth, as at the present time, is in full progress.—T. BAINES.

Flower Garden.

Auriculas.—All the plants reserved for seeding purposes will have been repotted, and by referring to previous numbers the character of the compost, size of pots, and treatment of the plants can be ascertained. Any seeds that have been saved will also be sown. We never get quantities sufficient to make it necessary to sow in pans—indeed, we usually sow two different lots of seed in a 5-in. pot, marking the division between the two with a small strip of lath. I use light soil in which to sow the seeds, and do not add any manure to it. Good loam four parts; one of leaf-mould and a liberal addition of sharp sand answer well. The lights have been kept over the plants rather more this season than usual, and the result of the closer atmosphere is that green fly has been troublesome. The best way (when the collection is small) of destroying this pest is to brush it off the leaves; or the plants can be dusted with Tobacco powder. Fumigating with Tobacco smoke is the cleanest plan if the frames are close. I would urge the importance of taking care of the seedling plants. Auricula fanciers find pleasure first in selecting certain varieties to cross for seeds, then crossing them and saving the seeds. They watch the development of the pods, and long for the time when the seed will be ripe. No time is lost in sowing it. Then the seedlings appear, and when large enough they are potted, and carefully tended until blooming time. The anticipation of something new amongst them keeps up the interest which might otherwise flag at certain seasons.

Carnations and Picotees.—As I write this after inspecting my collection I must record the fact that only six flowers are open, notwithstanding that the plants were pushed on in frames up to the end of April. Plants in borders and beds are at least a fortnight later still, and this is the date at which these flowers ought to be in full beauty. Attend to tying the flower stems to sticks as they advance in growth; for if this is neglected, some of the flowers will be heavy enough to snap the stems through at the joints. The flowers ought also to be finally disbudded; very weak plants and stems will support and bring to perfection one flower only, stronger stems two, three, and four flowers. Remove weeds from the pots, and attend carefully to watering; but do not use any manure water—the white in the flowers will be much clearer without it.

Hollyhocks.—As regards these, little information is necessary beyond that given last week. The sun, which has been shining rather brightly for a few days, has caused the leaves to flag; a good plan is to syringe, applying it well underneath the leaves, in order to check the development of red spider.

Dahlias.—These now require close attention; they should be looked over twice, or at least once, a week in order to thin out superfluous growths, and to tie up and place sticks to those that require

such supports. Trap earwigs by placing hollow Bean or Hemlock stalks near the top of the plants, and examining them every morning. Dahlias are looking very well indeed, and so far they have not required any water at the roots. Surplus growths may be used as cuttings, which will strike root in a cold frame, or more quickly in a gentle hotbed. These cuttings produce plants that may be grown in 3-in. pots, and will form what are termed pot-roots.

Pinks.—These are now in full beauty, and just a month later than usual. The blooms, however, never were larger or better laced than they are this year. Until this season I have not seen the Pink do so well except in Scotland, a circumstance which shows that it does not like the hotter, drier atmosphere of the south.

Pansies.—The same may be said of Pansies, which never do well in a hot, dry season, not even though mulched and watered. The sun seems to bleach the colour out of them, and neither these nor Pinks like much shade. It is to be regretted that fine show flowers—the white and yellow grounds with rich dark-coloured beltings, and the white, yellow, and dark-coloured selfs—are being so much displaced by the fancy varieties. These, with their bright colours and grotesque markings, are pretty enough, but they sadly lack the beauty and refinement of show flowers.

Hardy Cypripediums.—The stems of many of these have in ordinary seasons been decayed by this date, but as yet most of them are green and healthy looking. See that none of the pots become too dry, but on the other hand it is not desirable to over-water them, although it is better to err that way than allow them to suffer from lack of moisture. Syringe overhead twice a day, and shade from bright sunshine.—J. DOUGLAS.

Kitchen Garden.

Not the least of the many disadvantages of the present season is that arising from the late maturation of early crops, preventing their being used or harvested, and thus affording space for subsequent crops; of course, where spare ground is plentiful this inconvenience will not be felt. Shallots, Garlic, early Peas, early Cauliflowers, autumn-sown Onions, and the earliest kinds of Potatoes ought long ago to have been harvested, and as soon as they are lifted let the ground be cropped as follows:—on the Shallot, Garlic, and Onion ground put Lettuces, Endive, Turnips, and early Horn Carrots; on the Cauliflower ground, winter Spinach; and on the Potato ground, Broccoli or other kinds of winter Greens. If the ground was well treated for the preceding crops, no preparation beyond that of cleaning and levelling will now be necessary. We usually plant the main crop of Broccoli on the Strawberry plot that has done duty for two years. As soon as the fruit has all been gathered, the plants are planed off with spades, and the Broccoli planted between the rows in holes made with a crowbar, and filled in with fine soil. Under these conditions Broccoli thrives at least as well as on ground that has been elaborately prepared, putting out of the question the saving of labour and time. As regards Potatoes, the present outlook appears to be very dark, for all the mid-season and late kinds are as yet making but scant progress towards maturity, and if the murrain sets in—which it is almost certain to do very soon—in their present immature state they must entirely succumb. I would recommend that all early kinds, if anything like fully grown, should be housed at once, without waiting for the skins to get hard. This early lifting does not affect their keeping qualities, and their need be no danger of their going bad if dug up before there has been any trace of disease. Were it not that one is constantly being pestered to try some new kind, or afraid of being behindhand in Potato competitions, I would strictly confine myself to growing only first early sorts, with a view to lifting them ere they were in danger from disease. This appears to me to be the only remedy, and eventually we shall come to regard earliness in all kinds of Potatoes as second only to quality. If any of the seeds that were recommended (see p. 39) to be sown have not yet had that attention, any further delay will result in their not wintering successfully. Small Saladings, Mustard, Cress, Radishes, &c., may still be sown in open borders in small quantities weekly, and as French Beans are not likely to do much good outside, provision should be made for making a sowing forthwith, either in frames, or in pots to be introduced into houses or pits as room can be found for them.—W. W.

Indoor Fruit Department.

Early Vines from which the Grapes have been cut are manifesting an undesirable tendency to produce wood, and stopping, which is the only way to meet the difficulty and induce earlier ripening and resting, must be persisted in. Keep the houses as cool as possible, and the foliage clean and free from insects, which, now that the fruit is used, will be a comparatively easy task, as syringing may now be done whenever it may be thought necessary. If the borders are at all unsatisfactory, now is the time to see to them, either as regards the examination of old drains or making new ones,

or giving additional soil and top-dressing. Of course suitable weather must be chosen for such work, as it is very undesirable to be moving soil when it is in a pasty condition, both as regards the Vines and one's own comfort. Give air freely to Grapes colouring, but guard against cold currents, which are oftener the cause of "shanking" than the state of the soil or border, which generally gets the blame and sometimes perhaps rightly. A severe check of any kind, occurring at that critical juncture when the fruit begins to change from the sour to the saccharine state, will cause shanking, and perhaps there is no greater cause of that evil than over-cropping; and yet how slow we are to acknowledge the fact or to rest content with one good bunch rather than two inferior ones shanked. The quantity of wood being made by Vines in all stages of growth is something remarkable, so much so that it is difficult to keep pace with it as regards stopping and tying out, but the dull season demands that this should be done regularly, in order to afford all the light possible for the thorough ripening of the wood. Go over late Grapes prior to colouring and clip out all small or imperfectly fertilised berries, and if necessary tie up the shoulders of the bunches. All that are intended to hang on the Vines or keep long should be well thinned out, especially towards the middle of the bunches, else in the winter, should one berry crack or go mouldy, the entire bunch will be sure to follow. The unfavourableness of the season still renders fire-heat absolutely necessary in order to ensure the Grapes being ripe before the end of September.

Figs.—Although the first crop of these swelled off well there was a lack of flavour, for, apply fire and give air as freely as one may, they do not play the part of sun heat, and the Fig is perhaps more than all other cultivated fruits a sun-loving plant. It is, therefore, to be hoped that the second crop, which is now swelling freely, will be more fortunate as regards that flavour-giving element—sunshine. Expose the fruit as much as possible by keeping the shoots thin and well stopped back; should there be danger of overcrowding, it will be well to thin out not only young shoots, but some of the longest, barren, or naked ones; for, though as a rule all such pruning had best be deferred to the resting season, if done a little at a time, and at long intervals, no danger need be apprehended from bleeding. Thin the fruit to reasonable limits, taking off first all the unshapely ones, and next the smallest and those that are badly placed as regards light and air. Water liberally, and always with guano or other manure water, that is, if the roots are in confined borders, as all Figs should be; of course, if the roots have unbounded liberty, such artificial feeding would be injurious rather than otherwise, as it would tend to the production of gross unfruitful growth. Pot trees that have done fruiting must not be neglected; supply them with plenty of clear water and syringe twice daily. So long as the weather continues dull they will ripen best indoors, but if a bright period ensues, gradually inure them to bear full exposure on a sunny aspect, plunging the pots in leaves, cocconut-fibre, or cinder ashes, to render watering as infrequent as possible.

Peaches and Nectarines.—We have been bothered with black fly, which made its appearance on the trees just as the fruit began to ripen; hence fumigation, the best remedy, was out of the question. Tobacco liquor and soap suds, applied three days successively with the syringe to the affected parts only, so as not to injure the fruit, has freed the trees of the pest. Whenever such attacks are feared, it is well to fumigate as a preventive before the fruit has attained so advanced a stage. Ripening fruits cannot have too much air; the slower they mature the deeper will be the colour, more piquant the flavour, and they will keep longer after gathering than fruit ripened with express speed. When the fruit has been gathered be just as attentive to the wants of the trees as previously, an admonition all the more necessary seeing we are apt to think that when the crop has been gathered the trees will take care of themselves. Copiously water inside borders, and mulch with stable litter or droppings to prevent the soil from cracking. Trees in every stage of growth, except those bearing ripe fruit, syringe daily, and keep the shoots from overcrowding by timely pinching and tying.

Melons.—In ordinary seasons fire-heat might at this time be dispensed with, but under present conditions as regards weather brisk fire-heat is still needed in order to obtain full-flavoured fruit. A minimum bottom-heat of 70°, and the same of top heat are indispensable for crops approaching maturity, and air must be given freely whenever the weather is favourable. Keep the soil in a moderate state as regards moisture, and when watering is necessary let it be done thoroughly and always with water of the same temperature as that of the border. To some, the question of a few degrees difference between the temperature of the water used and that of the border may seem of little moment, but of this I am certain that it not unfrequently makes all the difference between a good crop and a bad one; indeed, it is by a combination of so-called little matters that success in most matters is attained. Stop and tie in successional plants, and carefully guard the foliage from injury

of every kind, exposing the fruit to light as much as possible. It is not yet too late to plant more Melons if wanted, but they should be got out without further delay.—W. W.

THE LIBRARY.

ESSENTIALS OF DIET.*

THIS is a useful little work, and if its prescriptions were followed medical men would find a large portion of their occupation gone, for one may lay it down as a general rule that most diseases of the digestive organs arise either from ignorance or from a wilful disregard of the laws which should regulate our diet. The oft-quoted proverb which tells us that what is one man's meat is another man's poison, although haekneyed, is nevertheless true, and the aim of the author and editor has been to point out the best means of distinguishing between the "meat" and the "poison." The diet that is "meat" to the stalwart, stolid labourer at the plough would be "poison" to the weak-framed student with finely strung nerves, and *vice versa*. The chapter which more especially concerns the readers of THE GARDEN is that on vegetable food. Commencing with a description of the cereals generally, the author very justly condemns the prevailing mania for purely white bread, and advocates the use of what is now generally known as whole-meal bread. The inner coating of the grain, which is removed during the process of dressing, is of very great value, for it contains the elements of nutrition for muscle, bone, and brain; consequently the more thoroughly this is removed in dressing the less valuable is the flour as a food. The author tells us that in the north of Germany oatmeal soup is a favourite diet, but he does not give any receipt for its preparation. He is wrong, however, in his description of the Irish stirabout, which he tells us contains Indian corn meal. This is a mistake, for stirabout is precisely similar to Scotch oatmeal porridge, the Maize meal being a modern innovation. He also omits all mention of the Italian polenta and the numerous American preparations of Maize. Vegetables generally he divides into four classes. 1. Sugary vegetables, such as Potatoes and Turnips. 2. Stimulants, such as Asparagus and Garlic. 3. Antiscorbutics, Salads, and Tomatoes; and lastly, Diluents, such as Cabbages, Sorrel, and Nettle tops. The dietetic characters of all our ordinary vegetables and fruit are given at length, and will be found useful to those who suffer from dyspepsia from eating vegetable food. The author, in speaking of seaweeds, very justly regrets that they are so much neglected as articles of food, seeing that they are richer in flesh-forming material than Indian Corn or even oatmeal. The editor adds an interesting chapter on the diet for singers and speakers.

C. W. QUIN.

SCHOOL GARDENS.†

MRS. MANN has done English readers good service in presenting them with the present translation of Dr. Schwab's account of his success in establishing school gardens in Austria. There is no adjunct to the schoolroom which in the hands of the skilful teacher can be turned to such profit as the school garden. Thousands of such gardens are in operation in Austria at the present moment, all of them being the fruit of Dr. Schwab's intelligent labours. Besides the opportunity that a school garden offers for the practical teaching of the first principles of agriculture, vegetable physiology, it may be also turned to account in various ways. The operations necessary for keeping a small garden in proper order are all healthy, and are looked upon by a healthy child as play and not work. Charles Dickens unconsciously enunciates a grand educational principle when he makes Mr. Squeers teach his boys botany by sending them to weed the garden. A handful of weeds in the hands of a teacher well acquainted with the Socratic method of teaching will give a child a greater insight into the phenomena of plant life than a knowledge of the meaning and derivation of half the sesquipedalian words that ever were coined. Not only this, the child's moral and intellectual faculties are pleasantly exercised and cultivated without his being aware of it, more especially his patience and watchfulness, for he soon finds out that he must wait for seeds to germinate and for flowers to blossom, and sad experience will soon show him that a very little neglect will kill the pets which he has taken so much pains to rear. Austria, France, Sweden, and even little Belgium, all have their school gardens. Where are ours? Has there been a single Board school

* "Essentials of Diet, or Hints on Food in Health and Disease." By the late E. H. Riddock, with corrections and additions by E. R. Shuldham, M.D., F.C.D., &c. London: The Homeopathic Publishing Company. 1879.

† "The School Garden; being a Practical Contribution to the Subject of Education." By Professor Erasmus Schwab, Director of the Military Academy of Vienna. Translated by Mrs. Horace Mann. New York: Holbrook & Co. 1879.

built during the last two years with a garden attached to it? and yet such an adjunct is as necessary for the proper teaching of vegetable physiology and botany as the black board is for teaching arithmetic. Mrs. Mann adds considerably to the value of Dr. Schwab's excellent little book by adding a number of practical suggestions of her own with regard to the best means of carrying out Dr. Schwab's plans. We cordially recommend Dr. Schwab's little work to all who are engaged in the education of the young, whether parents or teachers. By following its teachings many a pleasant little spot might be formed either in the home or school garden, or even on the nursery window sill, which would help our little ones to acquire a knowledge of those things of beauty which are joys for ever and which constitute the vegetable kingdom. C. W. QUIN.

TREES, SHRUBS, AND WOODLANDS.

Early Leafing in the Oak and the Ash.—Owing to the protracted wet season and the heavy masses of foliage considerable damage has in many places been already done to trees by falling branches, and by the browsing of cattle, so that it is difficult to maintain the usual neatness in parks and other places to which cattle have access. This is more especially the case with the Lime, the Beech, and the Ash. So far as the present season is concerned, the old calculation that a wet summer follows the appearance of the foliage upon the Oak before that upon the Ash, seems likely to be verified; for throughout this part of the country (Kent) the Oak had a considerable start. But observations extending over a number of years have convinced me that whenever a cold spring succeeds a severe winter, the Oak, on account of its being the deepest rooted, and therefore the least affected by the season, gets the earliest start; whereas during an early warm spring, the Ash, which on account of its shallower rooting first feels the sun's influence, takes the lead. Thus instead of predicting what may possibly follow in the course of the season, the relative appearances of the foliage upon these two trees afford certain indications of the weather which has preceded them.—B.

Disbarking Timber.—Considerable difference of opinion prevails as to the necessity for barking trees immediately after they are felled. In some cases, as in that of the Alder when cut for hop-poles, the durability of the wood is considerably increased by taking off the bark at once. But in other cases, and particularly in that of the Larch when used whole for posts, the preservation of the bark greatly prolongs the soundness of the timber. Thus I have seen the butts of whole Larch, which had been put up as posts in a fence with their bark entire, removed sound at the end of more than twenty years; while those which had been squared out by the saw and axe, were so decayed as to be almost worthless. Wherever the bark contains a conservative quality, or any substance which makes it repulsive to insects, it should be retained for as long a period as it will maintain its soundness; but after that time either by its retention of moisture, or by harbouring insects which prey upon the wood, it becomes mischievous. During the time that it remains sound the bark is also useful in preventing the cracking of the timber from the influences of the sun and air.—A. J. B.

Fremontia californica.—This strikingly beautiful wall plant produces its large yellow blossoms freely on spurs, and upon young shoots of the preceding year's growth. The leaves as they expand have, a short distance off, the appearance of those of a Hawthorn or flowering Currant, but upon closer inspection they are found to be of rounder outline, and of much softer texture than those of the Hawthorn. It looks beautiful when trained either horizontally or obliquely, and seems to flower best when cultivated upon the same system as that on which we grow the Peach. The long, fine shoots that are exposed to air and light, and which have room to grow and develop themselves and get thoroughly ripened, produce clusters of large yellow flowers which cannot fail to attract admiration.—*Gardeners' Chronicle*.

—This shrub is now flowering most effectively here and there throughout the country on sheltered walls, but in the Royal Botanic Gardens, Glasnevin, from whence we have received flowering specimens, it is now in perfection. As a rule, it will succeed best as a wall shrub, but in Devon and Cornwall it may be grown as a bush on a sheltered part of the lawn or shrubbery with every success, along with the Fire Bush (*Embothrium coccineum*), *Escallonia macrantha*, rare *Spiræas* of frutescent habit, and the exceptional *Xanthoceras sorbifolia*. It is Sterculiaceous, and nearly related to the singular Hand Plant of Mexico (*Cheirostemon*). The main point, however, is that it is a hardy shrub from the Californian Sierra Nevadas, and perfectly amenable to good culture in our gardens, and so distinct is it that no garden of any pretensions should

be allowed to be without at least one example of it, if not in bush form, at least on a sunny wall, where its wood may get so well ripened in autumn as to cause it to flower well during the following summer.—B.

—This has been flowering very finely at Messrs. Rollisson's during the past month. Its flowers are rich golden yellow in colour, and measure upwards of 3 in. in diameter; the calyx envelops the petals until they are about to expand when it falls entirely away. The plant in question is planted against a wall facing the west.—W. H. G., *Tooting*.

Yellow-flowered Horse Chestnut.—I remarked at Knap Hill the other day a yellow sport of the Pink Horse Chestnut, which is being propagated, and which will be an interesting addition as regards colour to the other forms of this ornamental flowering tree.—P. G.

Evils Resulting from Divided Interests in the New Forest.—The proprietor of the underwood must wish to prevent the growth of timber by which his crop is diminished; and it is for the advantage of those to whom the herbage has been granted that no wood should grow up of any kind. The whole is a perpetual struggle of jarring interests in which no party can improve his own share without hurting that of another.—*Extract from Report of Commissioners appointed in 1788*.

The Present State of Woodlands.—Instead of affording the pleasure which is usually derived from a ride or a stroll through their mazes, nothing can be more cheerless than the present appearance of woodland drives and footpaths. Rank undergrowths obstruct the pedestrian, and drooping and dripping branches spoil the pleasures which otherwise might be derived from a woodland ride. In sheltered spots with a tolerably dry subsoil, Firs, Pines, and many of the young deciduous trees have already made a good growth; but upon the cold clays and in the more exposed places last winter's transplants are languishing.—B. J. A.

Picturesque Willows.—The Willow in our landscapes is often an object of admiration, but it is among the neglected trees in what might be called ornamental planting, the best species not often getting a chance of forming the noble trees that we know them to be when they have full room for development. There are some good Willow trees in St. James's Park, and there are some wonderful ones in the English Park at Zurich. The curious specimen here figured occurs in France, and is one of the most picturesque trees of the kind to which it belongs. The tree bent over by a storm or other accident forms an arch.

A Gap in the Avenue.—"Let any one stroll along beneath a stately avenue of Elm or Beech. Three or four Elms are passed and are evidently sound, but the fifth—a careless observer might go by it without remarking anything unusual—is really rotten to the centre. At the foot of the huge trunk, and growing out of it, is a bunch of sickly-looking fungi. Thrust your walking stick sharply against the black wood there and it penetrates easily, and with a little pushing goes in a surprising distance; the tree seems undermined with rotteness. This decay really runs up the trunk perpendicularly. Look: there are signs of it above at the knot hole 30 ft. high, where more fungus is flourishing, as it always does in damp wood. The rain soaks in there and filtrates slowly down the trunk, whose very heart, as it were, is eaten away, while outside all is fair enough. Presently there arises a mighty wind, the tree snaps clean off 20 ft. above the ground, and the upper part falls a ponderous ruin, carrying with it one of the finest boughs of its nearest companion, and destroying its symmetry also. What a gap it has left in the avenue! In a minute the growth of a century gone, the delight of generations swept away, and no living man, hardly the heir in his cradle, can hope to see that unsightly gap filled up."—*The Gamekeeper at Home*.

Oak as a Substitute for Box.—In the vegetable garden at St. George's Hill, Byfleet, Oak is exclusively employed for bordering the walks. Acorns were sown some ten years ago, and the edging is now only about 6 in. in height. It is, I believe, clipped twice in the summer, and presents a very fresh, neat appearance throughout the season. The leaves, of course, fall in the autumn, but an evergreen edging to the kitchen garden walks can scarcely be considered indispensable. Mr. Rose considers Oak to be in many ways far preferable to Box. It does not need renewing or fresh planting, neither is it susceptible to injury, and the comparative ease with which it is made, and the inexpensive nature of the material, are great points in its favour. It is well known that Box edging requires a considerable amount of labour and care to keep it in good order, whereas the Oak thus treated forms a dense scrub, requiring but little attention to maintain it in good condition, and is capable of enduring with impunity a considerable amount of rough usage.—J. CORNHILL.

HORTICULTURAL IMPLEMENTS.

Lawn Mowers.—As regards these I am not going to recommend any particular maker, but only offer a few comments on the adaptability and advantages of the different sizes in relation to their usefulness. There are a good many different sizes of lawn-mowers, from 6 in. up to 3 ft. or more, but the work, in places where there is employment for a lawn-mower, is done in most cases by three or four sizes—the single or two-men machine, the donkey, and the horse machine. We have little hesitation in saying that all sizes besides these are to a certain extent useless, although plenty of inexperienced people are persuaded to invest in small machines. 6-in., 8-in., and 10-in. machines are recommended as suitable for women and boys; but it is soon discovered that to work even the lightest of the three is too much for a woman, or a boy either, and that it takes twice as long to go over the ground with it as it would with one 12 in. wide. Hence the exertion required is about six and half a dozen in the end. Such small machines are mere toys; and it should always be remembered that a lawn-mower cuts a less breadth than the actual width of the knives, as an overlap in cutting has always to be allowed, in order to avoid leaving a strip uncut at each journey. This overlap need not be more than an inch; but, unless the operator is expert at his work, he may perhaps lose

2 in. or 3 in. every journey he takes. This is a disadvantage in all lawn-mowers, but particularly in small ones. In actual work all sizes should be calculated at from 1 in. to 3 in. less than the width of the knives. Where an able-bodied man has to use the mower, a 14-in. or 16-in. is certainly not too large when the Grass is cut frequently, and kept as closely shaven as a croquet lawn; but when the Grass is allowed to get long before it is cut, then a 12-in. machine is as much as any one man can push or draw, and it is very hard work indeed, and such as the same man should not be called upon to do every day. It is by far the most economical plan to provide as large a machine as the man or the horse can work effectively; but a too large one entails loss of time, as the journeys are performed at a disproportionately slower rate, and more frequent rests are made. For two men 22-in. and 24-in. sizes are usually recommended; but as a rule the 22-in. is large enough; and, as a matter of fact, the 24-in. machines, of the best makers, are oftener worked by three men than two. This has been our experience, and we discontinued the two-men machine altogether, and employed a full-sized donkey machine instead, at a cost of 5s. per day, man and boy, against 9s. for the three-man, or 6s. for the two, and much more work was done. With the donkey machine, and one 12-in. one worked by a man, we can do as much work as was formerly done by a horse machine and the man one too. A horse machine is well enough for cutting large open spaces, but in pleasure grounds it leaves too many corners for the scythe, whereas a donkey machine can cut even round small flower beds, and what it leaves the 12-in. machine can cut in a short time. Just a word as to the construction of lawn-mowers. Our opinion is that the makers do not realise the importance of making their machines as light as possible, and that every needless pound of iron handicaps the working power seriously. Several of the machines in repute are heavier than they need be. One maker, for example, supplies solid iron handles for the shafts, weighing a good deal. The shafts themselves, also of iron, are generally too strong and heavy; and the crossbars and fixing might frequently be greatly reduced in weight, and thus lessen the exertion in working such machines. Makers may depend upon

it that the machine which is lightest in draught will always be the most popular if it be otherwise good.

Wheelbarrows.—This is an indispensable garden implement, if it may be so named; but, as a rule, those in use in private gardens are far too heavy and clumsy, being usually made by the country joiner, who looks to strength chiefly. Could not our professional horticultural builders supply an article of lighter yet strong make? Barrows made of heavy inch deal, with Ash shafts $2\frac{1}{2}$ in. to 3 in., legs, ribs, and wheels in proportion, and clumsy iron fittings, as commonly made, are too heavy by half for garden purposes, and impede the work, for a man cannot—or at least will not—take a heavy load on a heavy barrow.

Ladders.—What applies to barrows also applies to garden wall ladders, which sometimes are as much as a man can carry. The French employ ladders made, both spokes and sides, of fluted iron, and they are exceedingly light and handy. These are made for all purposes—for walls and trees, and for Grape trimming, &c., with a movable seat for the thinner. Telescope ladders are also used where a long ladder of portable dimensions is required.

Sweeping Machines, &c.—Among the machines that have yet to be produced for garden purposes is a Grass or leaf sweeper and an edging cutter. Both these have already been offered, but they do not meet the want. The sweeping machine is constructed on the same principle as the lawn mower, a brush being substituted for the knives; but it does not answer—it is too much of a “scrub.” Indeed, the same machine has been used for brushing carpets, but it is not popular for that purpose either. A machine to sweep a lawn must go with a “whisk,” and be driven by considerable power. Such a contrivance, on the principle of the hay-tedding machine, is, we think, quite possible. As to the Grass-edging cutter, nothing as yet approaches the shears in the hands of a good workman. They gather up all the Grass and projections; but the edging machine misses all that is out of the line of the revolving blade, and a boy has

to go after it and pick it off. The knives, too, soon get blunt and out of order. One of the latest introductions among tools are the American steel rakes, light handy tools, which are greatly recommended. We have tried them and found them wanting. Rakes are used frequently for other purposes than raking walks—such as cleaning out shrubberies, &c., and at such work we find the steel teeth to snap whenever they come against a stump, whereas an iron rake does not. It wears but does not break. A rake without a tooth is useless; hence steel rakes are not to be recommended for general work.—*Field.*

Rabbit-proof Plants.—In reply to “T. M.” (p. 64) allow me to state that the following device has been recommended to me, not precisely as rabbit-proof, but as a most certain means of getting rid of these pests: “Scatter or strew on the ground visited by rabbits small Lentils (*Ervum lens minus*, in French Lentillons), which will be greedily eaten by the rabbits, which will then retire to their burrows and will never show themselves again.” I cannot warrant the efficacy of the remedy, having never had an opportunity of experimenting with it, but it will be easy to put it to the trial.—M. J. M.

Twice-rooted Pollarded Willow.

THE FLOWER GARDEN.

CULTURE OF LILIES.

Mr. C. W. Dod (p. 31) seems rather to expect some notes from me on this season's Lily growing. I have but few to offer, but send them for what they are worth. I would add to his evergreen shrubs in the Lily bed, if he has not already done so, *Skimmia japonica*, the large-flowered variety of *Skimmia oblata*, and *Veronica Traversi*. Our gardens are all warm ones; it is probable that in colder districts somewhat different treatment may be required, and perhaps a more sunny aspect desirable for some species of Lilies; but here the more completely shaded from the sun and sheltered from the wind the better Lilies thrive. We have a good many beds in this garden at the sides of shrubberies and *Rhododendron* beds, completely sheltered from sun and wind, where many species of Lilies are planted. In one of these beds *L. auratum*, *L. pardalinum*, *L. canadense*, *L. californicum*, and *L. krameri*, undisturbed from last year, have stood the past wintry spring perfectly, and look thoroughly well; while *L. speciosum*, in the same bed, has some shrivelled leaves. In another bed, consisting of *L. krameri* and *L. speciosum*, all the plants are in perfect health, and promise fine blooms. In other beds *L. superbum* is growing strongly. We have a number of bulbs of *L. superbum* planted in moist parts of a wood in deep black virgin soil. When these are in full shade and shelter, nothing could be finer than their growth; but with the same soil and about the same moisture, where the sun has reached them after some of the spring frosts, they look wretched. Sun after frost has, of course, a most injurious effect on all Lilies. We have one long bed of *L. auratum* in the wood; half of this was in full shade, and the plants are strong and healthy; the other half caught the sun, and are spoilt for this year. The most trying part of the year for Lilies with us was part of last May. Early in the month I went into Perthshire to fish, leaving the Lilies, even in the dampest part of the wood, including a bed of *L. neilgherrense*, quite healthy. On my return, in rather more than three weeks, I found the *L. neilgherrense* all browned, and many of the *L. auratum* injured. This was, I think, as much caused by the excessive wet, which flooded part of the wood, as the frost; as in the dry half of the wood little injury was visible. Mr. Dod considers *L. californicum* a synonym of *L. canadense*. It is nearer *L. pardalinum*, and is distinguished from it by its brighter colour, larger spots, fewer flowers, and has a distinct white shade in the middle of the flower. Mr. Dod does not speak of *L. krameri*. In suitable situations it is easily grown, and is a lovely Lily in open quarters. We have one large potful, most of the stems having three flowers. It gives one a notion of what *L. krameri* ought to be.

Heatherbank, Weybridge Heath.

GEORGE F. WILSON.

SWEET WILLIAMS IN WET SEASONS.

NOTWITHSTANDING the dripping skies and cold sunless weather which we have experienced, Sweet Williams maintain an amount of gaiety that is most delightful. They are grand plants in the shape of masses, as those who see beds of them rods in length can testify; but few can realise the marvellous blooming power which single plants possess that have had plenty of space and liberal treatment. A Sweet William producing from forty to fifty heads of bloom is not an uncommon occurrence, but one difficult to equal amongst hardy plants. Every cottager who has a garden grows Sweet Williams, but, as a rule, they do not consist of the best kinds; their trusses of bloom are small and comparatively unattractive. Nevertheless, as a rule, the plants are well grown, for the simple reason that no trouble or skill is needed to grow them. Sown at the right time and planted at the right time, with sufficient room to develop themselves, they can hardly fail to flower well. There is, however, such a wide difference between good flowers and poor ones—between a good strain and a bad one—that it is marvellous such indifferent flowers should yet be grown. Given, however, a packet of good seed, it is well that it should be sown at the proper time, and that is in the month of May, as by that time the soil is warm enough to germinate the seed, and the plants so produced, if planted out into beds or borders about the middle of July, will make fine masses and carry a dozen or more stems the next summer.

If the plants are grown chiefly to obtain trusses of good size specially for exhibition, it is well to sow at midsummer and to put out the young plants at Michaelmas; these will throw all their strength into the production of one stem and head of bloom, which is invariably fine. With a good strain I have obtained in this way heads 9 in. across, and a stand of a dozen such heads would be specially handsome and striking. Show flowers, however, will have better properties than size of truss; added to this should be large, circular, strikingly-marked pips, a fine strain such as Barlow's

selection of Hunt's kinds, producing single flowers as large as a shilling and as perfect in shape. The flowers of Hunt's strain are remarkable for size of pip, very smooth even edges, and the regular character of the markings—a dark coloured ground edged with white being oftentimes as perfect as the edging of a gold-laced Polyanthus. To particularise the various markings would be impossible, because whilst many assume the usual feature of circlets, others will be marbled or of a self colour, but it is enough to say that of 1000 seedlings, perhaps there will be 100 diversely marked flowers, or even more. Hunt's strain, for all show purposes and chiefly because of the size of pip and smoothness of edge of the petals, is invariably regarded as the best.

The Auricula-eyed section presents more diversity than it is easy to describe in writing. The plants have the same robust habit, the heads of bloom are freely produced, and these are as large as Hunt's; it is in the flowers in which the difference is seen, and here smoothness of edge is rarely if ever found. The great charm of the strain is the pure white eye, which, when surrounded by a ground of some bright rich colour, renders the heads of bloom specially attractive. In many cases this rich ground has a white edging, but there is, beyond this special feature of the strain, an infinitude of markings that are as beautiful as they are varied. Some of the richest marked flowers would look well in a stand of blooms at an exhibition, but the absence of the smooth edge might unfavourably influence the judges.

In masses for summer decoration Sweet Williams are especially attractive. They produce over a large surface an even head of flower, and this is so varied as to at once arrest attention.

A. D.

ALPINE PLANTS AT HOME.

DURING an excursion on the Schneeberg (Austrian Alps) for the purpose of collecting Alpine plants for our newly-constructed roekery, we collected various plants, of which some notes may be interesting. The majority of the plants were found at elevations of from 3000 ft. to 6000 ft.; at this height considerable masses of snow are to be met with, even in summer. In moist, cool, shady situations near the snow I found great masses of *Soldanella minima*, flowering in the greatest profusion. At another place, close to the snow, I found the whole ground carpeted with *Primula minima* in flower. *Homogyne alpina* is to be found in great masses everywhere, intermixed with many other plants. Large tufts of *Armeria alpina* were very conspicuous. I also found two species of *Viola*, one with large dark blue flowers found growing in great masses, the other with little yellow flowers, rather rare. *Silene acaulis* grows in great masses, associated with *Gentiana acaulis* and *G. verna*, the last one of the most brilliant of Alpine flowers. *Ranunculus alpestris*, a diminutive species, was still in flower. In one very moist place I found *Pinguicula vulgaris*. *Alsine stricta*, now in flower, is a real gem amongst Alpines; its delicate white blossoms, produced in abundance 2 in. or so above its shining green leaves, make it an interesting plant for roekeries; I found it on rather dry places, much exposed to the sun. Of *Campanula alpina* I found only a few plants about 5 in. high, bearing deep blue flowers. *Bellidiastrum Michelli* resembles our common Daisy as far as the flowers are concerned, but they are much larger. *Pedicularis rosea*, which I found in flower, is not higher than 3 in., and its leaves being of a purple hue have a singular appearance. *Azalea procumbens* is growing there in great masses, its creeping stems covering slopes as densely as Moss, and finely in blossom. Of *Lycopodium Selago* I found only a few small plants. Amongst others, I collected *Biscutella lævigata*, *Bartsia alpina*, *Primula spectabilis*, *Saxifraga mutata*, *S. muscoides*, *Genm montanum*, *Ranunculus* (two species), *Salix herbacea*, *Polygala amara*, and a species of *Orehis*, most probably *O. Transsteineri*. I am interested to know how these plants will succeed on our roekery. At present we have potted them, and will keep them in pots until they get a little established before being planted out.

LOUIS KROPATSCH.

Laxenburg.

Cyrtanthus brachypetalum.—This is an apparently rare species of great merit, of which I do not recollect having seen any notice whatever. It is probably one of the good things collected by Mr. Cooper at the Cape, but on that point I may need correction. The flower-scape grows about 10 in. high, is of a glaucous purplish hue, and bears at its summit a nodding cluster of tubular flowers of a light orange colour, each flower being about 2 in. in length, with the six divisions of the limb very short and broad. It continues in bloom for a fortnight or more. The foliage is rather scanty, consisting in my specimen of two narrowly linear-lanceolate leaves, about as long as the scape. The species seems easily cultivated, and will certainly become popular when sufficiently multiplied.—W. T. I.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Hardy Orchids.—Many of these are now very beautiful in cool, moist places in gardens as well as in their native habitats. *Orchis maculata præcox*, with its crimson purple spires, and the different forms of *O. latifolia*, *O. Morio*, and *O. pyramidalis* are amongst the most showy. *Cypripedium spectabile*, planted out in a moist peat bed behind a north wall and sheltered from the wind when in bloom, is now in lovely condition. I have also grown it in common garden earth surfaced with *Hydrocotyle vulgaris*, a way in which it forms a good window plant. The best place for it, however, is a sheltered peat bed where it may become established permanently.—F. W. B.

Flame Flowers Picturesquely Grouped.—These plants have by their great beauty and vigour shown their own merits so eloquently that there is no need for us to say a word in their favour. There may be other kinds to add to our collections, and rare ones to make more common, but otherwise *Tritomas*, or Flame Flowers as they may be aptly called, have become accepted as among the treasures of our collections of hardy flowers. There is, however, something still to be done as regards their arrangement. They are

and some perfectly double. We have now some fifty plants in bloom each varying from 3 ft. to 9 ft. high, and furnished with from four to forty stems. Being so tall they are seen at a long distance off, planted as they are at the back of a herbaceous border. The large amount of rain which we are still having appears to be what they enjoy, but they dislike wind. It is to be regretted that they are not more grown than they are, for it is seldom one sees anything like a collection of them. As regards culture they should have liberal treatment, slugs should be kept from them, and they should be safely secured against wind. Thus managed they will continue in bloom from two to three months.—J. C. F.

A Pretty, but Troublesome Aquatic.—The *Ranunculus aquatilis* has been frequently recommended as a pretty aquatic for ponds and lakes, and it deserves all that can be said in its favour in that respect, for it produces sheets of pretty flowers early in summer, but I would not advise any one to plant it in a pond which it is desired to keep free from weeds as it is almost as troublesome as the "American Water-weed." Some years ago a small patch of it appeared in a reservoir here which supplies the establishment with soft water. Where it came from I never learned, but it had not been

Flame-flower on margin of Lake Longleat, 1873.

occasionally planted in excess, so as to neutralise the good effect they might otherwise produce, and they, like many other flowers, have suffered from being, like soldiers, put in straight lines and in other geometrical formations. It is only where a fine plant or group of plants is seen in some green glade that the true beauty of the Flame Flower is seen, especially at some little distance off. Although not exactly belonging to the very free-growing and extremely hardy genera of plants recommended for the wild garden, they are so free in many soils that they might with confidence be recommended for that purpose, and our sketch shows a picturesque group of them planted in this way. It would be delightful if people having country seats would study more the effects to be realised from certain types of plants. For instance, a well and tastefully placed group of these Flame Flowers would for a long time in autumn be a most effective feature in the landscape of a country seat; and there are various other plants to which the same remark applies, though perhaps to none better than these in the later months of the year.

Larkspurs.—It is impossible to speak too highly of these good and useful plants, which are valuable even in a cut state for filling vases and for similar purposes. They produce stems from 3 ft. to 9 ft. high, clothed with green leaves and with flowers for a distance of from 2 ft. to 3 ft. Many of them are single, others semi-double,

seen near the place before. The first year it was not interfered with, and the next year it nearly filled the pond and had to be cleared out; but the following summer it again appeared and soon quite filled the pond, and had to be cleared out by men on rafts at no little expense and trouble. This went on for several years till it was at last deemed advisable to clean the pond out and cement it all over. This was last year, and up to this date the *Ranunculus* has not appeared, but we do not feel sure of it yet. It propagates itself from seed, and when it finds congenial quarters it will cover acres in a short time. The leaves and flowers are nothing to the roots, which float in the water forming dense masses and entail the most part of the labour in clearing; but this applies to deep water chiefly. Our coachman also made the discovery that the plant communicated a dye to the water in which it grew. Wishing to tighten the tier of one of his carriage wheels he plunged it in the pond for a few days. It was painted blue and white, and when it came out it was discovered that the white had changed to a pale yellow colour which no amount of scrubbing would remove. This dye also renders the water unsuitable for laundry purposes.—J. S. W.

Veronica Traversi.—Like your correspondent R. A. J. (p. 55) I find this New Zealand *Speedwell* to be one of the handsomest of out-door plants, especially when planted in an open place. It has,

too, withstood the past winter quite uninjured, though in an exposed situation. The finest specimen of it that I have yet seen is now in full beauty in the herbaceous ground at Kew, where it forms a round symmetrical head quite 4 ft. across and a yard high.—W. G.

Bouquet Pink.—This is a double-flowered variety of *Dianthus petraeus*, a small-fringed snow-white Pink and sweet scented. It is an abundant bloomer, and I believe but little known.—T. WILLIAMS, *Ormskirk*.

THE KITCHEN GARDEN.

GARDEN FOOD.

SIR HENRY THOMPSON has two extremely interesting and useful articles on food and feeding in the two last numbers of the "Nineteenth Century," from which we extract a few of the passages referring to the garden food portion of the question.

"I have not hesitated to say that Englishmen generally have adopted a diet adapted for a somewhat more northerly latitude than that which they occupy; that the cost of their food is therefore far greater than it need be, and that much of their peculiar forms of indigestion and resulting chronic disease is another necessary consequence of the same error. They consume too much animal food, particularly the flesh of cattle. For all who are occupied with severe and continuous mechanical labour, a mixed diet, of which cereals and legumes form a large portion, and meat, fish, eggs, and milk form a moderate proportion, is more nutritious and wholesome than chiefly animal food. For those whose labour is chiefly mental, and whose muscular exercise is inconsiderable, still less of concentrated nitrogenous food is desirable. A liberal supply of cereals and legumes, with fish, and flesh in its lighter forms, will better sustain such activity, than large portions of butcher's meat twice or thrice a day. These things being so, a consideration of no small concern arises in relation to the economical management of the national resources. For it is a fair computation that every acre of land devoted to the production of meat is capable of becoming the source of three or four times the amount of produce of equivalent value as food if devoted to the production of grain. In other words, a given area of land cropped with cereals and legumes will support a population more than three times as numerous as that which can be sustained on the same land devoted to the growth of cattle. Moreover, the corn land will produce, almost without extra cost, a considerable quantity of animal food, in the form of pigs and poultry, from the offal or coarser parts of vegetable produce which is unsuitable for human consumption.

"Thus this country purchases every year a large and increasing quantity of corn and flour from foreign countries, while more of our own land is yearly devoted to grazing purposes. The value of corn and flour imported by Great Britain in 1877 was no less than £63,536,322, while in 1875 it was only just over £53,000,000. The increased import during the last thirty-two years is well exhibited in the following extract: 'In 1846 the imports of corn and flour amounted 17 lb. weight per head of population; in 1855 they had risen to 70 lb. per head; and in 1865 to 93 lb. weight per head of population. Finally, in 1877 the imports of corn and flour amounted to 170 lb. weight per head of population in the United Kingdom.'*

*

"The supply of garden produce ought in this country to be singularly plentiful; and, owing to the unrivalled means of transport, all common vegetables ought to be obtained fresh in every part of London. The contrary, however, is unhappily the fact. It is a matter of extreme regret that vege-

tables, dried and compressed after a modern method, should be so much used as they are for soup by hotel-keepers and other caterers for the public. Unquestionably useful as these dried products are on board ship and to travellers camping out, to employ them at home, when fresh can be had, is the result of sheer indolence or of gross ignorance. All the finest qualities of scent and flavour, with some of the fresh juices, are lost in the drying process; and the infusions of preserved vegetables no more resemble a freshly-made odoriferous soup, than a cup of that thick, brown, odourless, insipid mixture, consisting of some bottled 'essence' dissolved in hot water, and now supplied as coffee at most railway stations and hotels in this country, resembles the recently-made infusion of the freshly-roasted berry. It says little for the taste of our countrymen that such imperfect imitations are so generally tolerated without complaint.

*

"On salad so much has been written that one might suppose, as of many other culinary productions, that to make a good one was the result of some difficult and complicated process, instead of being simple and easy to a degree. The materials must be secured fresh, are not to be too numerous and diverse, must be well cleansed and washed without handling, and all water removed as far as possible. It should be made by the hostess, or by some member of the family, immediately before the meal, and be kept cool until wanted. Very few servants can be trusted to execute the simple details involved in cross-cutting the Lettuce, Endive, or what not, but two or three times in a roomy salad-bowl; in placing one saltspoonful of salt and half that quantity of pepper in a tablespoon, which is to be filled three times consecutively with the best fresh Olive oil, stirring each briskly until the condiments have been thoroughly mixed, and at the same time distributed over the salad. This is next to be tossed well, but lightly, until every portion glistens, scattering meantime a little finely-chopped fresh Tarragon and Chervil, with a few atoms of Chives over the whole. Lastly, but only immediately before serving, one small tablespoonful of mild French vinegar is to be sprinkled over all, followed by another tossing of the salad.* The uncooked Tomato, itself the prince of salads, may be sliced and similarly treated for separate service, or added to the former, equally for taste and appearance. Cold boiled Asparagus served with a *mayonnaise* forms a dish, of its kind not to be surpassed. At present ranking, when the quality is fine, as an expensive luxury, there is no reason why, with the improved methods of cultivating this delicious and wholesome vegetable, it should not be produced in great abundance, and for less than half its present price. As to the manifold green stuffs which, changing with the season, may be presented as salad—their name is legion; and their choice must be left to the eater's judgment, fancy, and digestion, all of which vary greatly.

*

"Very unsatisfactory is the supply of vegetable and dairy produce to our great city, particularly of the former. It must be confessed that our market at Covent Garden, in relation to capabilities for effective distribution of fresh vegetables, &c., would disgrace a town one-fifth of the size of London. Nineteen-twentieths of its inhabitants cannot obtain fresh green food on any terms, and those who succeed pay an exorbitant price. I think I am right in saying that a really new-laid egg is a luxury which a millionaire can scarcely ensure by purchase; he may keep fowls and with due care may obtain it, not otherwise. The great staple of our bread, commonly called 'baker's bread,' is unpalatable and indigestible; and I sup-

* "Statesman's Year Book, 1879, p. 258.

* A salad for five or six persons is supposed.

pose no thoughtful or prudent consumer would, unless compelled, eat it habitually—used as it nevertheless is by the great majority of the inhabitants of this great city—any more than he would select a steak from the coarse beef whose proper destination is the stock-pot. Let any one compare the facilities which exist in most foreign towns for obtaining the three important articles of diet just named, with the parallel conditions afforded by London, and the inferiority of the latter will be so manifest as to become matter of humiliation to an Englishman. I do not raise any question of comparison between our own markets and the Halles Centrales of Paris, covering as they do nearly five acres of closely utilised space, with enormous vaults beneath, in direct communication by tramroad with the railways; nor of the well-stocked Marché St. Honoré, and others of less note. To many among the thousands of tourists who frequent the public buildings of Paris, an early morning survey of the fish, flesh, dairy produce, vegetables, fruit, and flowers which the Halles Centrales display, and the scarcely less remarkable exhibition of Parisian and provincial life brought together there, present one of the most interesting and truly foreign spectacles which the city affords.

*

“To the long list of needed reforms I have ventured to advocate in connection with this subject, I must add the want of ample and accessible markets in various parts of London for what is known as country produce. I do this not only in the interest of the millions who, like myself, are compelled to seek their food within the limits of Cockayne, but also in the interest of our country gardeners and housewives, who ought to be able to supply us with poultry, vegetables, and eggs better than the gardeners and housewives of France, on whom at present we so largely depend. We may well be grateful to these small cultivators, who, by their industry and energy, supply our deficiencies; but the fact that they do so does not redound to the credit of our countrymen.”

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

The Potato Disease.—This sad visitation is now affecting early sorts of Potatoes generally, and a continuance of the present weather can but lead to its wholesale appearance amongst all kinds and in all parts of the kingdom. As usual, it presents itself first in those kinds that are most matured, and then spreads over all breadths alike until not a green leaf is left. Added to a fruitless year, this disease will be a heavy blow to market gardeners and others who grow Potatoes on a large scale. It seems useless to hope for better weather, as the summer is passing away so fast that even should it come it will be too late to benefit many things. The disease would appear to have struck Potatoes on the Continent even before it has appeared here, and if the crops are as largely affected there as has been stated in the daily papers, there will be but few foreign Potatoes to import. This fact should induce importers to look to America, where they have had some hot weather, and where, perchance, may be found a fairly healthy crop. But the regulations regarding the Colorado Potato Beetle may interfere with our imports from that quarter. Should prices reach the high figure during the winter that is anticipated, there will be a great outcry if it is found that the American crop is practically excluded from our markets.—A. D.

Planting Asparagus in July.—We are just now engaged in planting-out Asparagus, and I am of opinion that summer planting will one day become a common practice. The system is inexpensive, and there is no trouble in filling up blanks, as in the case of spring planting. Seeds that were sown last March in an early situation are now good plants. We are not nearly so particular as we used to be about soil; we however choose a good situation where the soil is deepest—not necessarily heavy—but of a generous open character. We plant in lines instead of in beds, as we used to do, in order to keep with the times as regards size, but in small gardens the bed system of planting will have to be retained for the sake of economising space. I have planted as late as August with plants from 18 in. to 2 ft. high, rather than defer planting till the following

spring. It is the deep trenching, the purchase of old plants, and the planting of them in cold spring weather, that ruins the prospects of many a well-meaning cultivator. Where the subsoil is bad, that is to say, where it is either too heavy or, it may be, gravelly and poor, the best way is to add to the surface a few inches deep of good open compost, and muleh and feed the plants regularly during the growing season. Those who manure heavily in winter, expecting to reap the benefit the following season, are committing an unconscious error. The growing season is the proper time to invigorate the roots, which should have a good run, as they are gross feeders and soon exhaust the soil in a limited root-space. And, again, climate has a good deal to do with fine heads of Asparagus as well as soil and other conditions. Take, for example, the acres of Asparagus that are grown along the Formby coast between Liverpool and Southport, where the finest produce is grown at comparatively little expense. The open soil and sea air act like magic upon the crop.—*Gardeners' Chronicle.*

Potato Dibber.—For planting Potatoes on light well-worked land an implement like that of which the annexed is an illustration is extremely convenient. Some London market gardeners plough in their potatoes to save labour, but where they have to be planted as an after crop, the land being already occupied with cabbage or other green produce, this implement is frequently employed with advan-

Dibber used in Market Gardens.

tage. A man dibbles the holes and boys or women drop in the seed tubers and then cover them in with a hoe. A modification of this contrivance has been used by us as a pot plunger, and also for planting out decorative plants in the flower garden for the summer display. Any handy man or amateur may make it for himself, or a carpenter could produce it for a trifling sum.—B.

AMERICAN NOTES.

Bearing Years of Orchards.—Mr. Johnson stated at a meeting of the Western New York Farmers' Club that last year (which was an abundant year all through the country) eight acres of his twelve-acre orchard were loaded with fruit, and from some cause the other four acres were barren. The trees on these four acres are now bearing profusely. Mr. Pierce said that last year just as the blossom buds were opening and promising a heavy crop, a severe hail storm entirely destroyed the whole. This year the trees are loaded. The question occurs what is the best way to remove the crop of blossoms during the abundant year in order that plenty of fruit may be had the "off" year.

Early Peaches.—The many new varieties of the Peach which have originated within a few years, ripening their fruit two or three weeks earlier than any known twenty years ago, are beginning to make a distinct change in the markets. The Alexander was ripe in Cherokee county, Texas, on the 9th of May, and within a few days of that date supplies were received in New York from the same latitude in Georgia. The Gulf States, when supplied with bearing orchards, will doubtless furnish this fruit about the 1st of May, and increased facilities for conveyance north will give us ripe Peaches so

early that we can enjoy them, in connection with our own, for at least six months in the year.

Raspberries in the West.—Mr. Hussmann gives in the *Rural World* his experience with the newer Raspberries in Missonri. The Turner, Thwack, and Brandywine have withstood the winter without injury, and he congratulates cultivators that at last a red Raspberry has been secured in the Turner that is hardier than the Blackcaps.

Yosemite Plum.—Mr. Isaac Hicks, of Long Island, states that this Plum, found among the Sierras of California, is a profuse bearer of medium-sized fruit, and adds that it seems Curculio-proof. He saw many of the Plums with the crescent mark, but none had penetrated. The fruit is said to be somewhat astringent, and we suspect that it is not of the highest flavour.

Strawberries in New Jersey.—The Strawberry season is about over with us. We had dry, hot weather just before the berries began to ripen, and after they had begun to ripen it became excessively wet, so that they went into market in bad order. Kentucky gave an excellent crop; Charles Downing did very well, having much less of the leaf blight this year than usual. The Albany Seedling is not much cultivated with us; being near market, we can manage softer varieties, but where they were cultivated the crop was generally poor. Crescent was quite defective, except where it was well mixed with some staminate variety. It seems to be well established now that to ensure a good crop some staminate sort must be near the Crescent. The largest and handsomest berries we had this year were from Sharpless plants, set last September; the yield was not large, but the quality was excellent. Decidedly the best Strawberry we have had here, all things considered, was Miner's Great Prolific. It is thoroughly healthy and vigorous; its berries are large, handsome, of good quality, and very productive. Its season of ripening is about the same as that of Charles Downing.

Pogonia ophioglossoides.—This is generally found growing in moist localities—the thick, fibrous roots being most luxuriant when growing in good live Sphagnum, situated so that it is neither too wet nor too dry. In growing this beautiful plant, I found it to succeed best in half-decayed Sphagnum, mixed with charcoal to keep it sweet. When in flower it should not experience any approach to dryness, and the atmosphere of the house should not be very dry, or else red spider is sure to attack the foliage, which greatly mars the following year's growth and flower.

Arethusa bulbosa.—The flowers of this fine Orchid appear before the leaves. They are of a bright rose-purple, varying in the shade of colour according to the position and locality in which the plant is growing. It is much rarer than the Pogonia, but I have met with it in some particular localities in considerable quantities. In cultivation it requires the same treatment as the Pogonia. Care must be taken to get the leaf as well matured as possible. Coming as it does after the flower, the leaf is apt to be neglected. A good outdoor position for growing these Orchids is a shady, moist spot having a northern exposure—using for soil a mixture of well-rotted manure and Sphagnum. During winter, the bed in which it grows is better to be protected with some rough mulch, for it appears that when taken from its moist home and placed in higher ground, it loses its extremely hardy nature. Upon no consideration, however, should it be treated as a tender plant, or failure is sure to be the result.

Lady's Slippers.—The different kinds of Cypripedium found wild throughout the country are remarkably pretty. *C. spectabile* has scarcely a rival in the long list of species in this family. It is found wild in bogs throughout the Northern States, and succeeds well in cultivation. It requires a soil composed of good fibrous peat, and, when sending up its flower spikes, plenty of moisture. I have found it do well when treated as a greenhouse plant, by withholding water when at rest, but giving sufficient to keep the roots in a healthy condition. *C. acule* requires a rather shady position, and succeeds in a soil composed of fibrous loam and good fresh leaf-mould.—*Country Gentleman*.

Birds'-nests in Plant Houses.—Some kinds of birds seem fond of building their nests in glass houses. We frequently have robins' and wrens' nests built on the hot-water pipes, and being rather considered friends than foes they are allowed to remain unmolested, and generally hatch their brood in safety. We have at present a pair of wagtails that are bringing up a second brood in hanging baskets in the conservatory. It is singular how soon they become familiar with the men at work close by them, and how busily they pick up any insects which they find amongst the plants.—JAMES GROOM, *Linton Park, Maidstone*.

GARDEN DESTROYERS.

THE HEART AND DART MOTH.

(*AGROTIS EXCLAMATIONIS*.)

FARMERS are perhaps as a rule more annoyed by the caterpillars of this moth, which are very destructive to turnip crops, than gardeners, but the latter are also frequently troubled by them in the flower as well as in the kitchen garden. They, as well as the caterpillars of the dart moth (described in *THE GARDEN* of Jan. 4, 1879), are often known by the name of the grub. This insect is very common, and may be found in nearly all parts of England, and is also generally distributed over the rest of Europe. Turnip roots appear to be their favourite food, and at times several may be found feeding on one root, which they soon damage by gnawing great holes in it. Young plants they sometimes quite destroy by eating the root right through, just below the crown; Radishes, Lettuces, Endive, Cabbages, and Artichokes, are also frequently attacked by them in the same manner. In the flower garden, China Asters and Carnations, are usually their victims. These caterpillars cannot climb well, although they can walk with great rapidity, and as soon as they have demolished one plant at once travel off to another perhaps some yards off, but they have been known before they have nearly attained their full size to hide in the blossoms of Carnations, and devour their petals and ovaries. As these caterpillars are night feeders, and remain hidden in the earth, or under stones and clods of earth, during the day, they are seldom seen unless carefully looked for, which makes it all the more difficult to take any steps for their destruction. It is evident that nothing applied to the surface of the soil during the day would be likely to kill them in any numbers; but certain appli-

The Heart and Dart Moth
(*Agrotis exclamacionis*).

cations may be used which will render the plants distasteful to them. If the plants are well watered with salt and water in the proportion of $\frac{1}{4}$ oz. of salt to 1 quart of water, the caterpillars will be driven away; but if the salt gets washed off the plants they are liable to be again attacked. Soot or lime spread very thickly on the ground, and well dug in, or laid in a ring round each plant, will keep them from attacking such plants. Watering well with soap and water is recommended as being very effectual in bringing the caterpillars to the surface, when they should at once be destroyed; hand picking is perhaps the most successful plan. Search should be made for them under all stones and clods of earth, and if possible the earth near any plant which has been attacked should be removed, when the caterpillar will generally be found near the roots; this may be done during the daytime, and at night the plants should be carefully looked over with the help of a lantern. In its other states this insect is even more difficult to destroy, as the eggs are very small, and are laid in the earth; it would appear to be impossible to do anything to destroy them, particularly as they are generally laid near growing crops, except encourage birds and insects which might feed on them. In the chrysalis state they are some inches below the surface of the soil, and no artificial means which we can use, short of turning up the earth and collecting them, can harm them. Their deadly enemies the moles destroy great numbers of them; moles, however, cannot be encouraged in a garden, although the amount of good they do by destroying various grubs and chrysalides can hardly be over-estimated. The moths lay their eggs, about the end of June or the beginning of July, in the earth near some suitable plant, which the young caterpillars at once begin to attack; they continue feeding until the winter, when they bury themselves at the roots of the plants, and generally pass the cold weather in a semi-torpid condition surrounded by a ball of earth, which they form around themselves as a protection, some 2 in. or 3 in. below the surface of the ground. In the early spring they reappear and begin to feed again; at the end of May, or the beginning of June, they re-enter the earth and become chrysalides, in which state they remain for about a month. The moths measure from $1\frac{1}{2}$ in. to $1\frac{3}{4}$ in. across the wings when fully expanded. The males may be distinguished from the females by their antennae, which are thicker and finely toothed, whilst those of the females are very fine and smooth; the lower wings of the females are darker than those of the males. In both sexes the thorax is of yellowish drab, with a dark transverse band or spot on the edge in front. The general colour of the front wings is the same as that of the thorax, but their upper edge is somewhat darker, and ornamented with various darker and paler markings. Near the side margin on each

wing is a paler waved band, and towards the centre of the wings are two darker marks, one of which is supposed to resemble a heart; the other, which is nearer the base is long pointed and placed longitudinally and is imagined to be like a dart or note of exclamation. From these markings the name of the insect is derived. Between the heart-shaped spot and the base of the wing is a dark ring with a dark dot in the centre. The lower wings are whitish in the male, with the upper margin and nervules brownish, and dark brown in the female. The caterpillars are about $1\frac{1}{2}$ in. long when full grown; their heads are brown, with rather darker mouths; and their bodies are of a pale dull violet, or lilac colour, the back being paler with a tinge of yellow, on either side of this stripe is a darker indistinct band; down the middle of the back is a double brownish line, which is sometimes hardly to be distinguished; the under side is greenish white. The first segment of the bodies is somewhat horny and brownish, with dark spots; each of the remaining segments have on the back four small black tubercles arranged in pairs, and others on the sides, each tubercle bears a fine hair. There are eight pairs of legs, one on each of the first three, the sixth, seventh, eighth, ninth, and last joints. The chrysalides are brown.

G. S. S.

Unpacking Plant Cases and Boxes.—The unpacking of nailed-down cases is necessary work in every garden, and although a really handy man will extemporise tools for the purpose, yet it is often most desirable and really the most economical plan in the end

Implements for opening packing cases.

to have implements specially made for the purpose. Amongst the tools used in Her Majesty's Customs Department for the opening of cases and boxes from abroad we recently noted the mallet and chisel now illustrated as being those most used by the officials. An ordinary carpenter's wooden mallet costs but little, and any blacksmith will fashion the other implement, which is of iron or steel, and from 15 in. to 18 in. in length. It is a combination of the cold chisel, lever, and wedge, and may even be used as a screw-driver if ground moderately sharp at the lower end.—B.

THE WALTHAM CROSS NURSERIES.

ALTHOUGH the present season has been so generally unfavourable for Roses, yet there is much that will well repay a visit to Messrs. William Paul & Son's nurseries at Waltham Cross, where the primary consideration is rose culture. Here may be found not only all the popular varieties and choice novelties in cultivation, but fine old kinds of every description, such as the Moss, Provence, Damask, and a host of others, for which happily a taste still lingers. Every method of culture and propagation too is here fully demonstrated, and it is a source of much interest to observe the preference which some varieties have for certain particular methods of treatment. One of the leading features is an avenue several hundred yards in length, planted on each side with rows of Conifers, which apparently have been planted in good material, judging by the thriving specimens of such beautiful kinds as *Picea lasiocarpa*, *P. nobilis*, *P. Nordmannia*, *P. Pinsapa*, various species of *Pinus*, *Cupressus*, *Juniperus*, and others. As a foreground to these there is a series of circular beds consisting of various kinds of Roses pegged down so as to form a compact mass. This is a very desirable mode of treatment and one that should be more exten-

sively practised, as it is highly conducive to productiveness. The beautiful Tea-scented Safrano, for instance, is an admirable bedding kind, as are also others of a like constitution. The old sorts, too, make a fine display grown in this way. The most conspicuous kinds here were: Village Maid, Ohl, Cynthie, Madeleine, Countess Muranais, &c. The main bulk of the collection is, of course, grown as standards, and these occupy a vast area. Amongst the newest and most noteworthy of those in flower may be mentioned the beautiful Duchess of Bedford, a Hybrid Perpetual of rare merit, and one which well answers to its description, being of a dazzling light scarlet-crimson, perfectly globular in form, and a vigorous grower. The Countess of Rosebery is another superb novelty which will doubtless be appreciated; its colour is a brilliant carmine, and the form as perfect as we have met with. Boieldieu, Alfred K. Williams, Princess Charlotte de Tremouille, Souvenir d'Adolphe Thiers, Madame Gabriel Luizet, Grand Duc Nicholas, and Mrs. Laxton comprise some of the best of the newer kinds, though such sterling varieties as May Quennell, Queen of Waltham, Magna Charta, Glory of Waltham, Red Dragon, Princess Christian, and many others, still hold their own against all new comers. The nursery for seedlings contains many new claimants for public favour, and though they are as yet unnamed, we consider that several are decided improvements on existing varieties in their respective tints, and we are pleased to see amongst them the nearest approach to a pure scarlet that we know of, which will be a great acquisition. Tea-scented Roses are also grown in a variety of ways, though but few were in flower in the form of open-air standards. Several roomy houses are devoted to an extensive collection in pots for forcing purposes, consisting of the best varieties adapted for that purpose, such as Isabella Sprunt, Maréchal Niel, Climbing Devonensis, Safrano, Madame Berard, Niphotos, and others. Hybrid Perpetuals are also largely grown under pot culture, but these are all now plunged in open-air quarters.

Although, as has been stated, Rose culture is the primary consideration, this nursery is well stocked with a large collection of all kinds of fruit trees in various stages of growth; also with Conifers, and trees and shrubs, both evergreen and deciduous. Amongst these the golden-leaved Elder and Catalpa and the golden-leaved form of *Spiraea opulifolia*, together with other variegated kinds, were remarkably effective, and compensated in some measure for the paucity of bloom amongst trees and shrubs generally at this time of the year. The golden-leaved varieties of Yew, too, are very handsome, especially the erect-growing Irish variety. An extensive collection of Camellias of all sizes in pots placed in the open air in a partially-shaded situation show, by their healthful appearance, that such treatment suits them, for more vigorous plants we seldom met with. These are wintered in spacious houses, which are constructed so as to admit of all possible light at the season when they most require it.

W. G.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

JULY 22.

THE following plants were awarded first-class certificates on this occasion, viz. :—

Pescatorea Klabochorum (Lawrence).—A beautiful Orchid, resembling in form and size *Bollea celestis*. The colour of the flowers is a pure waxy white, with the tips of the segments rich plum. The lip is of the same colour, surmounted by a golden crest.

Iris Kämpferi var. Imperatrix (Elwes).—A very fine variety raised by Herr Max Leichtlin, of Baden-Baden. Its flowers are very large, being nearly 7 in. across, with broad segments pure white and crimped at the edges, and tinged with deep violet.

Sarracenia atro-sanguinea (Bull).—A handsome variety of *S. flava*, having the upper part of the lid of the pitcher-like leaves of a deep red colour and conspicuously netted below with the same colour.

Tradescantia multicolor (Bull).—A distinct species, similar in habit to *T. zebrina*. Its leaves are beautifully variegated with various shades of green, purple, and a creamy-white tint, the whole surface shining with a silvery lustre.

Bromelia Binoti (Williams).—One of the most ornamental of all the cultivated Bromeliads. Its leaves, which are from 3 ft. to 5 ft. long, beset with spines at the margins, assume a gracefully-drooping habit. The colour of the older leaves is a mixture of red and green, whilst the younger foliage is bright red without the saturation of green.

Coleus James Barnshaw (Bull).—A variety of robust habit, having rather small and finely-toothed foliage, quaintly marked with various shades of golden and crimson.

Coleus Dr. Brushfield (Lloyd).—Also a vigorous-growing kind with large leaves, coarsely toothed on the edges, and variegated with gold, green, and crimson colours.

Second-class Certificates were awarded to:—

Carnation The Queen (Turner).—A pretty variety with blossoms of good size and form, pure white with faint pencillings of pink.

Rose Isabella Ward (Ward).—A seedling variety said to have been obtained by crossing Baronesse Rothschild and Sombreuil. It is a strong grower, and blooms well in autumn. A desirable variety, and one which probably would be better in a more favourable season.

Mr. Elwes showed an interesting collection of cut flowers, consisting of Calochorti, Brodiaeas, various kinds of Alliums, Gladioli, of which some were remarkably fine in colour, *Milla laxa*, *Murrayana*, and the new *M. longipes*. A hardy species of *Bomarea*, probably *acutifolia*, was also shown from the same garden; it has small flowers of a crimson hue with a central dark blotch. From Sir Trevor Lawrence came a superb example of *Odontoglossum coronarium* with a cylindrical head of blossoms 13 in. long and 8 in. through; to this a cultural commendation was given. From the same collection came also a small plant of *Dendrobium formosum* var. *giganteum* bearing very large ivory white blossoms from the base of the stems, whereas usually they are produced at the points. Mr. Bull contributed, in addition to the plants enumerated above, a flowering example of the beautiful *Dipladenia Brearleyana*, *Sarracenia reticulata flava ornata*, a fine unspotted form of *Lilium auratum* named *virginalis*, *L. Leichtlini*, *Browni*, and *neilgherense*, several new varieties of *Coleus*, the brilliant *Hemantanthus Kalbreyeri*, and a singular form of *Beheveria metallica*, the leaves of which bear numerous wart-like excrescences. It is aptly named *E. earunculata*. The same exhibitor also showed a plant of the curious Bull's-horn *Acaëia* (*A. sphaerocephala*), furnished with its horn-like, spiny stipules. From the Victoria Nurseries came a beautiful *Anthurium* named *Walnewi*, with large cordate leaves of a metallic bronzy-green lustre; also *Adiantum mundulum* and *dissectum*, two desirable novelties both dwarf in growth. A group of well-grown plants of *Coleus* came from Mr. R. Lloyd, Brookwood, amongst which were some interesting new kinds. Mr. Cannell, Swanley, showed an admirable collection of cut blooms of *Verbenas*, comprising several new seedling and named kinds of great beauty; also a collection of flowers and tuberous-rooted *Begonias*, *Fuchsias*, and *Sweet Williams*. A group of cut blooms of *Picotees*, *Pinks*, and *Carnations* were sent by Mr. H. Hooper, Bath. From the Slough Nurseries came a fine group of cut blooms of show *Pelargoniums*, comprising the newest kinds, also a few plants of the beautiful Tree *Carnation A. Alegatière*, with its fine bright scarlet blooms. Messrs. Veitch & Sons showed the double-flowered variety of *Begonia Veitchi*, a handsome kind partaking of the habit of the single-flowered variety, and with well-formed blooms of a deep cerise tint. The same exhibitors also contributed a numerous collection of cut blooms of *Roses*, comprising most of the leading varieties, in fine condition. A similar contribution came from Messrs. W. Paul & Son, Waltham Cross, amongst which were the following new varieties, viz., *Midnight*, with flowers of a deep maroon colour, of good form; *Masterpiece*, *Lord Bacon*, *Pride of Waltham*, *Marchioness of Bute*, and *Crown Prince*. A fine group of cut blooms of *Kämpfer's Iris* (*I. Kämpferi*) was shown by Messrs. Barr & Sugden, amongst which were many new seedlings of unusual merit. Mr. A. Boxall sent a fine seedling *Pelargonium* named *Miss Bell*, a kind having a vigorous habit and large trusses of flowers of a pleasing pink colour. A pretty Ivy-leaved form, with cerise-coloured flowers, came from Mr. George, Putney Heath. *Alutylon roseum multiflorum*, a desirable pink-flowered variety, of good habit, was shown by Mr. H. Williams, Finchley.

Fruit.—Of this there was but a small supply, a few Melons only being contributed, but none were considered of sufficient merit to receive certificates.

Spiræa palmata at Coombe Wood.—This beautiful hardy perennial forms a fine feature in Messrs. Veitch & Son's nursery where it thrives remarkably well, some plants of it measuring from 4 ft. to 5 ft. across. The value of this plant for decorative purposes cannot be over-rated, for nothing can be prettier than its broad feathery heads of deep rosy blossoms, which are thrown well up above the bold palmate foliage. Its novel congener *S. elegans*, which is said to be a hybrid, is also well represented, but its pale pink flowers are not nearly so effective as those of the foregoing kind.

ANSWERS TO CORRESPONDENTS.

Hardy Palms in Flower.—Allow me to inform your Hampshire enquirer (p. 72) that we have at present a large specimen of *Chamærops humilis* in full bloom that stood out last winter wholly unprotected. I am inclined to think that the long winter which we have experienced has had something to do with inducing flowering owing to the plants having had such an enforced season of rest. The large branched heads of bloom are decidedly ornamental, and the fact that these Palms have stood the winter so bravely should, I think, induce their extended cultivation wherever fine foliage effects are appreciated.—J. GROOM, *Linton, near Maidstone*.

Single Cordon Pears.—"A. D.'s" trees (p. 72), if double grafted, ought to prove satisfactory, the variety *Marie Louise* being one of the best varieties and surest croppers grown; I would recommend that stopping should not be done too early in the season, as, if done before the base of the shoot gets partially ripened, a mass of weakly wood is the result. In a wet, sunless summer like the present all trees are prone to run to leaf and wood growth; therefore leave the shoots for the present rather longer than usual, merely pinching the point at six or seven leaves from the base, pruning closer in winter. I would recommend oblique rather than vertical training.—J. G.

Diseased Cedar of Lebanon.—The fresh soil is not likely to have injured the tree (p. 72) unless it was placed round the collar so as to cover any part of the base of the trunk; that, of course, would cause death, and some of the symptoms are consistent with deep covering, but probably other causes are at work. One would like to know if this is a sudden affection, or whether it has been in existence for any length of time. The presence of fungus may be the cause of the decay of the tree's vital powers, or it may simply be an effect following some other cause of weakness. If it can be ascertained that the failure of the health of the tree is due to fungus, or to placing too much soil round the base, the removal of the cause may perhaps save it—in the former case by removing as much soil as can be done conveniently from above and around the roots, and deluging every part about them with soft water, or soft scattered about and watered in and the roots covered with fresh sweet soil. Soot is a fine restorative in any shape.—E. H.

Garden Workmen.—Will you kindly inform me how many men, besides a qualified head gardener, will be required to keep in order a place of the following dimensions: Kitchen garden, 2 acres; Grass to be kept mown, 2 acres; foot-paths, 1½ mile; carriage drive, ¾ mile; conservatory (permanent plants), 50 yds. by 7 yds.; conservatory (part permanent plants, but requiring a good many pot plants), 19 yds. by 10 yds.; early Vinery, 9 yds. by 4 yds.; second early Vinery, 9 yds. by 4 yds.; late Vinery, 12 yds. by 3 yds.; stove, 5 yds. by 4 yds.; cold pit, 7 lights; two 3-light frames? Ripe grapes will be expected in the first week in June; early forced Strawberries and French Beans also expected. The conservatory to be supplied with plants (succession) grown in the stove and Vineries; about 5000 bedding plants will also be required. The place will have to be kept in good order.—H. [To be able to answer this question satisfactorily one would require to live for twelve months as superintendent of the garden in question. I have, however, gone carefully into the matter, and think that for such a garden not less than six men (including a head gardener), and a boy or woman to weed walks, &c., would be required to keep it in anything like moderate style, either as to neatness or productions.—W. W.]

Eranthemums.—A. B. H., *Birmingham*.—The material on your *Eranthemum* leaves is of animal origin. You say "ants infest the house," so do aphides and mites, judging from the abundant stock on the leaves sent. No doubt these pests cause the mischief, though we cannot agree with you that they are exactly "responsible" for it.—S.

Questions.

Rippingille's Garden Propagating Frame.—Will any of your correspondents kindly state their experience respecting this frame? My own is that the frame is excellent, but the heating apparatus is not good. It is constantly getting wrong as regards the wick, and once wrong it is quite impossible to get at it to remedy it. I have had two of the stoves, and both have gone wrong in the same way; the screw refusing to turn the wick either up or down. The defect apparently arises from cheap construction, but this ought not to be, as the charge for the lamp alone is a guinea. The rectification is so simple that it would be worth Mr. Rippingille's while to attend to it. At present the apparatus is almost useless for winter work, as the derangement of the lamp might imperil the safety of valuable plants.—A. R.

Woodlice.—Can you give me any suggestion as to how to get rid of these in a Melon house? or how to preserve the Melon plants from destruction caused by them? They have destroyed a whole household of healthy plants, barking the stems, and waiting apparently till the plants are well grown, with fruit ready to ripen. The house is a "lean-to," heated with hot-water pipes. I have put soot round the bottom of the stems, and poured boiling water along the sides with no effect. A few Cucumber plants in the same house are untouched.—W. C. S.

Fruitless Peach and Nectarine Trees.—About three years ago I had my garden wall, which was very old and dilapidated, faced with Portland cement and then wired for my fruit trees. I also use copings during hard frosty weather. The aspect is south. For the last three seasons I have had no fruit, and this year the Peach, Nectarine, and other trees are most shabby. Is there any cause for this except the weather? Are the wires bad for fruit trees? and is it also a mistake to have faced the old wall as I have done? if so, is there any remedy? I should be very thankful for advice.—R. F. C.

Early Beatrice Peach.—I should be much obliged if some of your subscribers will give their personal experience of this Peach; mine is that, though about five weeks earlier than the best mid-season Peaches, it is quite worthless. Rivers' Early York seems also a very inferior Peach. Dr. Hoag, three weeks earlier than the above standard, is of fair size, good colour, and of excellent flavour.—A SUBSCRIBER.

Heating.—Will you give me a few hints about heating forcing-pits? The bottom-heat may be given, I believe, with slate tanks, galvanised tanks, or piping; which of these plans is best? If the last, should the piping lie on a solid surface, or have a space left underneath it? What is the best material to use between the piping and the soil?—H. B.

Window Flowers for Winter.—What can I grow and get into flower so as to be good-sized plants for furnishing the windows of villas and working men's windows inside, so as to be ready for this next autumn and winter? Which are the best *Pelargoniums* to grow for winter flowering, and the best mode of culture for them for winter? If you could give me a list of any plants which would do for the purpose (it does not matter how common), of which I could get seed or cuttings for pot culture to come in for this autumn, winter, and spring, I should feel obliged.—ROSE

"This is an art
Which does mend Nature : change it rather : but
THE ART ITSELF IS NATURE."—*Shakespeare.*

PROTECTING STANDARD FRUIT TREES.

A STRIKING instance of the value of protection for fruit trees has come under my notice this spring. The owner of a Green Gage Plum tree conceived the idea of sheltering it from the frost with some bast mats. A few long poles just sufficiently high to clear the branches were inserted here and there amongst the boughs and around the tree. The mats were then simply cast over the tree, resting in that position on the ends of the stakes. In a general way the mats were removed in the morning, but oftentimes in cold weather they remained on for two or three days at a time. The tree being a standard there was naturally always a free current of air upwards ; so that the little covering did not appear to exercise the slightest weakening effect upon it. The fruit set well, and there are now upon that tree more Plums than could be found upon any fifty unprotected trees in the District ; in fact, it is the only tree that is bearing a full crop in the neighbourhood. The owner of that tree will be well repaid for an hour's labour expended in arranging the protection, and the few minutes' daily labour in putting on and taking off the covering.

The idea has often occurred to me that more might be done in this way than is generally attempted. We go to the expense of buying and planting fruit trees, occupy valuable space with them, and then allow the frost to deprive us of the fruits of our labour. Once in five or six years, perhaps, we obtain a crop of fruit from trees that have taken years to grow, and which are fairly capable of yearly yielding a good return for our care. A small outlay would suffice to ensure a good amount of fruit in most gardens. One would not of course try to protect large standard trees, but pyramids, small standards, and trees in the form of bushes might be secured against frost at a small outlay of both time and trouble. In the case of the Plum tree in question no difficulty was experienced in protecting it, although it is quite 9 ft. in height ; moreover, besides the protection securing fruit for us, the shelter really appears to exercise a beneficial effect upon the tree itself. The bitter drying winds and chilly rains are warded off with the effect of assisting the development of the foliage, and thereby promoting the formation of healthy bearing wood for the ensuing season. It is well known that the damage is not always finished when the fruit is cut off, but that an inclement season makes itself felt in the diminished vigour of the tree. This may often be remarked in the case of the Vine, which is sometimes so injured as to require two seasons to recover.

Strawberries, again, which are an uncertain crop in the open air, may be secured against frost at a slight expense, and the protection has a most marked effect both upon the time of ripening the fruit and its quality. Some few seasons ago I was taught a lesson in regard to this matter. The months of April and May that year were very inclement—frosts succeeded frosts, and so severe were they that every Strawberry bloom was cut off almost before it could expand. The out-of-doors crops were in many places ruthlessly destroyed, and many acres of good plants were rendered quite barren. The autumn previous I had dibbled in a quantity of runners in 4-ft. beds, intending to plant them out in the spring. Circumstances so willed it that this could not be done, and, as they were coming finely into bloom, it occurred to us that we might use a quantity of old boards then lying about for protecting them. The idea was thereupon carried out ; two stout pieces of quartering were laid so as to run with the beds, and the boards were laid closely upon them, thus completely covering in the plants. Every evening, just before the sun passed off from the beds, they were covered, thereby securing and storing up for the night a certain amount of solar warmth. It will be readily understood that by this means the fruit was all saved, and, ripening early, much of it realised 7s. per lb. in the market. I can safely affirm that this was the most profitable crop of fruit ever grown here. That year canvas-covered beds fared almost as badly as the unprotected quarters, the frost going through the canvas and cutting off the blooms, whilst those that were more efficiently protected escaped and amply repaid the labour expended upon them. I should add that on cold days the boards were often not removed. That which most impressed me was the extra luxuriance of the plants, the foliage of which assumed a deeper hue, and the growth altogether was more satisfactory than that of those fully exposed. The Presidents which were gathered from these beds were some of the finest I ever saw, single crowns of no great strength, furnishing larger and more highly

coloured and finer flavoured fruit than did large well-developed stools in the open quarters. The main point is to cover efficiently ; the thin covering generally used is often inadequate when a piercing frost occurs, and the mischief is almost invariably done in one or two nights. Could these two or three, or perhaps only one frost, be warded off a good crop of fruit would be secured.

This subject is well worth the consideration of the owners of small gardens. Amateurs who love to tend their own trees, and to whom the loss of their fruit is a great disappointment, might, with a little management, always make sure of some fruit. Covering and the necessary appurtenances once bought would, for such a purpose, last for years, and would be one of the best of investments. It is grievous to go through garden after garden and to find them quite devoid of the fruit so much desired, and which a little forethought and outlay would have ensured.

J. C. B.

OPEN-AIR GRAPES.

THIS season affords little encouragement for cultivating Vines out-of-doors for the purpose of obtaining crops of ripe Grapes. That such can be obtained this year is out of the question, and it is doubtful whether any fruit will be gathered that will be ripe enough even for wine making. One, or even a couple of bad seasons, however, should not discourage those who may desire to experiment on open-air Vine culture from doing so, as we now and then get summers sufficiently warm to ripen crops, and thus fully compensate for losses in other seasons. I have this year planted Vines against the piers of a south wall, that is again backed by a belt of trees, and the position is a very warm one. These I propose to carry up to the top of the piers, and then divert the leaders right and left along the upper part of the wall, thus utilising space that the Tea Roses planted against the wall will not occupy for some time to come. The sorts are various and include Frankenthal, Madresfield Court, Sweetwater, and Royal Muscadine. Some of these may prove too tender to mature fruit, but they make good growth, at all events, and in such a position may, during a very hot season, produce fairly ripened Grapes. In any other but a warm situation, and where there is an absorber of heat like a brick wall, I fear the chances of ripening are small. A thick wall or the side of a house absorbs, during sunshine, a large amount of warmth that is given off during the night, and thus the Vines receive ripening assistance that is sadly wanting in the case of those trained to stakes in the French Vineyard fashion.

Without doubt, the best general sorts known in this country and suitable for outdoor culture are the Sweetwater and Royal Muscadine (white kinds), and the Ciotat, or Parsley-leaved and small Black Cluster. Mr. Fenn used to grow the Esperione at Woodstock in bygone years, but rarely got the fruit to ripen so as to be acceptable to the palate, although on the south front of the rectory ; the best ripened Grapes came from a branch that grew up around a brick chimney, the small additional warmth that passed up the flue helping to mature the fruit. He, however, grew Grapes only for wine-making, and therefore he could use them if only about three parts matured, but at that stage no one, as a matter of course, could have eaten them ; still, riper Grapes in the open air are rarely obtained in this country than are produced about Woodstock. The best and ripest bunches of the Ciotat which I have seen were gathered from a Vine growing over an oft-used oven ; this fact, and the illustration afforded by the chimney, shows that stored heat or that artificially obtained, is absolutely necessary to ripen Grapes in the open air. To the inhabitants of our towns and populous districts better Grapes are offered in the autumn from abroad than can be grown in this country in the open air. Let the home-grown Sweetwaters and Clusters be ever so ripe, they will always be excelled by the Spanish fruit that is so largely imported to this country in casks, and packed so well in Cork dust. I have purchased beautiful fruit at the varying prices of 2d., 4d., 6d., and 8d., per lb., fruit such as is at once sweet, ripe, and wholesome, and most acceptable to children. At these prices home-grown fruit would barely pay, and, indeed, to find a market, would have to be sold for less money.

To produce a home-made wine may be desirable where strong intoxicating malt liquors are so much drunk, but few persons know how to produce a palatable drink ; it is either mawkishly sugared and thick, or intensely acid and rough. Mr. Fenn is probably the best maker of home-made wines in England, as his gold medal award confirms, but even his liquors, pure and highly fined as they were, rarely suited the palates of those who had been accustomed to sherry, claret, and hock. They were too pure and too devoid of spirit. Rhubarb and Gooseberry, separate or combined, produce pleasant wines, quite as good, and far more wholesome than can be made from Grapes. These, moreover, can be easily grown and by any one, and their conversion into wine is less difficult than is the case with Grapes.

A. D.

CULTIVATION OF THE STRAWBERRY.*

THE Strawberry has long been an inhabitant of our gardens, having been known in London as an article of ordinary consumption as far back as the beginning of the fifteenth century. The numerous varieties now in cultivation are the offspring of several species introduced from time to time into this country from various parts of the world. Its cultivation is both simple and easy, and when skilfully managed it will amply repay any trouble or pains taken to produce it in perfection.

The soil most suitable for the successful cultivation of the Strawberry is a good deep rich loam, resting on a free and open subsoil. Soil that contains a good deal of decomposed trap rock will produce the largest and finest-flavoured fruit. In selecting ground for the formation of a new plantation of Strawberries, that which has been occupied by Onions, Cauliflowers, Celery, or other similar crop, for which the land has been previously well manured, should be chosen. In autumn, as soon as the ground has been cleared of its summer crop it should be trenched to the depth of 2½ ft. to 3 ft., according as the nature of the ground will admit, applying at the same time a heavy dressing of good cow manure, which should be placed in the bottom of the trench. The ground should be left in ridges so as to expose as much of its surface as possible to the influence of the atmosphere during the following winter. If the ground be of a light sandy character it will be much improved if, in addition to the manure, there be added a quantity of road scrapings, or of good, strong, heavy loam. If, on the other hand, it consists of a heavy, stiff clay, the addition of coarse sand or lime rubbish, together with a good dressing of hot lime, will do much to improve the fertility of this description of soil.

The best time for planting the Strawberry is about the end of February or the beginning of March, according to the season and the state of the weather. For this operation take advantage of a fine sunny day when the soil is dry. The ground, which had been trenched and ridged the previous autumn, should now be made level and dug over with the spade or digging fork. When ready drills should be drawn with a hoe, as if for sowing Onions. The distance between the rows should be 2½ ft., and 2 ft. from plant to plant in the row; perhaps in very strong rich soils, some varieties, such as President, Sir J. Paxton, and others with large foliage, will require as much as 3 ft. between the rows. It is better always that plenty of room be afforded them, not only for the convenience of cleaning the plantation and gathering the fruit, but, for what is of far more importance, that each plant may be fully exposed to the sun and air during the end of summer and in autumn, so that the crowns may be thoroughly ripened.

The young plants which have been taken from the old plantation at the end of the previous summer, and planted in nursery lines on a warm sheltered border, should now be carefully lifted and planted with a trowel. After planting the ground around the neck of the plants and between the rows should be trodden firmly with the feet, and afterwards hoed with a Dutch hoe merely to level the surface, loosening it as little as possible. When the ground is thus made firm the plants are not so prone to run into foliage instead of throwing up flower scapes, which they are very apt to do if the ground about them be rich and loose.

After the plantation has been completed the ground should be kept clear of weeds, all runners taken off as they make their appearance, and the surface of the ground frequently stirred with the hoe. Should the weather be dry the plants will be much benefited by frequent and heavy waterings. Some cultivators have a practice of growing such crops as Onions, Parsnips, or beetroot between the rows the first year. This I consider a decidedly bad practice, which should be avoided by all means. It not only robs the ground of the nourishment that should properly go to the Strawberry, but will also to a great extent shade the plants from the rays of the sun, which is a greater evil, and prevent the free circulation of air amongst them, upon which depends, in a great measure, the success of next year's crop.

Top-dressing between the rows is very beneficial to the Strawberry, as it serves to keep the ground moist, and affords proper nourishment to the plants. For this purpose good cow manure should be used; it may be put on in the autumn, or in the spring, just as the plants start into growth. I prefer to apply it in the end of autumn, as the enriching principles of mulching are washed down by the rains during the winter, and will cause the plants to start away with greater vigour in spring. About 1 in. of clean straw should be placed on the top of the mulching just as the flowers begin to open.

From the time the blossom begins to appear till the fruit is ripe the plants should never be allowed to suffer for want of water. Strawberries, when in active growth, require a large amount of mois-

ture, and should the weather be dry at this period frequent waterings will be necessary.

As soon as the fruit is all gathered the plantation should be gone over and thoroughly cleaned. Remove the material that has been used for top-dressing, and cut off with a knife all runners and decaying foliage, so as to admit plenty of light and air to the heart of the plants, being careful, however, not to cut away too much of the foliage. To cut off the foliage indiscriminately, as practised by some, is most injurious, and tends to seriously weaken and destroy the health of the plants. After the ground is cleared the surface should be lightly stirred with a fork, care being taken not to disturb the roots. Digging between the rows with the spade should never be practised, as the principal feeding roots will be destroyed in so doing; besides, the Strawberry, as already stated, always produces the best crops in firm solid ground.

With regard to the length of time a plantation should be allowed to remain on the ground, much depends upon the nature of the soil and the mode of treatment. In districts where the soil is naturally rich, and of a character adapted to the growth of the Strawberry, the plants being kept clear of runners and receiving an annual top-dressing of rich material, will continue to produce good crops of fruit for six or eight years, but on ordinary soils, even with the best of treatment, they will not continue to bear profitable crops after the third or fourth year. My own practice is to renew the plantation every third year, and I always find that the best fruit is produced the second year after planting.

The varieties of the Strawberry have increased to such an extent of late years that it is really a matter of some difficulty to make a good selection. Those kinds, however, should be chosen which have been proved by experience to succeed best in the particular soil of the locality in which they are to be grown, as many varieties will produce good crops of fruit in one kind of soil and be almost worthless in another. The kinds which we have found to succeed best with us—our soil being of a light nature, with a gravelly bottom—are Keen's Seedling, Garibaldi, British Queen, President, Sir Joseph Paxton, James Veitch, Dr. Hogg, and Elton Pine. James Veitch is, I consider, the finest Strawberry in cultivation.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Late Strawberries in Pots.—At the present time (July 24) I am gathering excellent Strawberries from pots, and in all probability shall do so for a week or more to come. I gathered my first dish on March 2nd. The varieties which I grow are Keen's Seedling and President—varieties which are equally good either for early or late bearing. It may be easily imagined how useful I find them to be this trying season for outside fruits. As yet I have not been able to gather a good sound dish of Strawberries from beds in the open grounds, thus showing how requisite it is to secure a full supply of good runners at the present time when they are plentiful. The best way as regards having them extremely late in pots is to plunge them in ashes in some cool situation, allowing them to grow away in spring according to the weather, the result being that one is able to have good sound fruits in cool houses, to which the plants may be removed from the open ground should the weather be against the setting of their blooms outside; but if sufficiently favourable for them to remain in the open ground so much the better.—H. A. M., *St. Vincent's, Grantham.*

Raspberries.—These are a heavy crop with us this year, but the ripe fruit is beginning to suffer from the incessant downpour of rain that we are getting. We have them trained in rows, with double wires stretched from iron standards; and by having the strongest canes 5 ft. high, and cutting the weaker ones down close to the lowest wire, we get the whole space covered with fruiting sprays. After tying is completed, a heavy dressing of manure is spread on the surface, and during summer all unnecessary suckers are removed, but in the formation of young growth sorts vary considerably. The Prince of Wales, a free, strong-growing kind, sends up abundance of shoots that are already 7 ft. high, while the Fastolf, an excellent fruitful kind, is sparing as regards young growth; the latter having a tendency to fruit in autumn frequently leaves the bearing wood for next season thin and weak. This variety, therefore, needs and well repays good cultivation and liberal top-dressing. The cultivation of Raspberries is largely extending in some parts of Kent, as there is always a ready sale for the fruit at remunerative prices.—J. GROOM, *Linton.*

Plants and Fruits in the North.—In Westmorland, within sight of the sea, the red and white varieties of Weigela and *Deutzia gracilis* were only just in the height of their bloom (which was more than usually profuse) on July 21, and some of the Syringas will not be in flower before August. In this and most of the other north of England districts Currants, Gooseberries, and some of the

* Read at the meeting of the Scottish Horticultural Association on July 1 by Mr. Alexander McKimmon, Melville Castle, Midlothian.

hardier Plums are much more plentiful than in the southern parts of the country. In some places that I have seen Currant and Gooseberry bushes are literally breaking down with the weight of their crops. Pears are bearing a moderate sprinkling; Apples partial, a few kinds moderately full, but the majority are thin, and in some cases there are none at all. Cherries appear to be more plentiful in the north than in the south.—P. G.

THE INDOOR GARDEN.

KARATAS HUMILIS.

THIS Bromeliad is one of the most interesting of the genus, whether from an ornamental or a scientific point of view. It was first badly figured and described by Jacquin in 1781, in his "Icenes Plantarum," Vol. I., fig. 60 (not 35 as given in the *Revue Horticole*), under the name of *Bromelia humilis*. Jacquin's plate gives but a poor idea of this beautiful plant. It is strange that though this plant was figured sixteen times in various publications between 1762 and 1862, it has never been properly reproduced. Whether this is caused by its slowness of growth or from its only being rarely seen in flower we know not; the specimen from which the accompanying figure has been taken has only been in our possession since the spring of 1876. It was in March, 1877, that we first saw it in flower, an event heralded some two months previously by the central leaves assuming a brilliant vermilion hue, thus simulating large bracts. This vivid coloration of the central leaves is peculiar to many of the Bromeliads. These coloured leaves often form their only decoration, the flowers being simply useful organs without any great beauty of form or tint. The annexed figure, which is greatly reduced, will give an idea of the general habit of this plant. It is a singular fact that amongst Karatas this variation in colour of the central foliage occurs regularly every year at the proper time, whether the plant shows any blossoms or not. This fact has been observed in the Karatas Legnelle and in the *Bromelia agavæfolia*, which ought certainly to be classed as a Karatas. With those varieties which are flowerless, this coloration of the leaves lasts just as long as in the case of those which flower. Besides this, as soon as the inflorescence has made its appearance, these brilliant hues fade out of the central leaves and the plants resume their normal appearance. The late Dr. C. Koch describes a plant of *Karatas humilis* which flowered in 1859 in the hothouses of Messrs. Mathien, of Berlin, in the following terms, which differ somewhat from those of Jacquin in being more exact: "In its general habit *Bromelia humilis* (as it was then called) approaches *B. Karatas* (L.), but it has fewer and shorter leaves, which are more curved and perfectly flat on the upper surface, without any central depression, thus closely resembling *Agallostachys Pinguin*. The inflorescence hardly appears above the leaves. The flowers are solitary and sessile on the superior convex portion of the peduncle, and the points of the three divisions of the corolla barely issue from the spathes which protect them. The central leaves become coloured, but they never assume the intensity of hue which is to be found in the majority of the *Agallostachys*." The specific name *humilis* well suits this enormous vegetable spider, which, in spite of its unfriendly look, ought to find a place in every collection, especially if grown on a bracket or in a suspended basket.

C. W. QUIN.

many. The fine compact-growing, free-flowering variety just named is rosy-pink in colour, except the mouth of the tube, which is white. It is a fine addition to these easily-grown, profuse-blooming subjects, and most useful, coming in as it does about the time when *Chrysanthemums* are in flower, and with which it associates well either in a cut state or in the shape of plants.—P. G.

TROPICAL PERIWINKLES.

THE merits of *Vinea rosea* and *alba*, both old-fashioned plants, are not so fully appreciated as they should be by the generality of plant growers. They are neat in habit, free in growth and floriferous: they are by no means difficult to manage, but they require rather different treatment from that which is generally accorded them, in order to realise their true worth. They are often grown in a strong heat amongst a miscellaneous collection of stove plants, where they fail to receive that amount of light and air which is so necessary for the maturation of the wood. When subjected to this treatment their blooms are apt to be drawn up in a meagre manner, and they altogether fail to attain that bushy, vigorous habit which distinguishes them when placed in conditions favourable to their requirements. The very best place in which to grow them is in a light pit, either plunged in or placed on a gentle bottom heat. There enjoying a maximum of light, and being constantly supplied with those conditions of heat and moisture which they delight in, they grow vigorously and produce flowers in profusion. If this convenience cannot be accorded them, they may be very well grown upon a shelf near the glass in a stove or intermediate-house. *Vincas* are easily propagated by means of cuttings made of half ripened wood. If inserted in silver sand, placed in the stove or propagating house, under a hand-glass, they will take root freely. When fairly rooted, let them be inured to the ordinary atmosphere of the house, when they may be potted off into thumb pots, using fibrous peat with a good admixture of silver sand. As soon as they are fairly established, they should be placed in cooler and more airy quarters, where they will get well hardened by the

Karatas humilis.

autumn. By subjecting them to this treatment, and by pinching them back as required, stocky, hardy little plants will be formed, and the production of strong flowering plants the next season will be comparatively easy. In September they should be placed in a house where the average temperature is sufficient to keep them in health without in any way exciting them into growth. As the days shorten gradually diminish the supply of water, allowing them sufficient only to keep the fibres healthy and the foliage from suffering.

About the middle of February they may be shifted into 2½-in. pots, using a compost of equal proportions of loam, leaf-mould, and peat. Place them where they may receive an increase of 10° of heat, keeping them as near the light as possible. As soon as they are well established, shift them into 4-in. pots, and if it is desired to have larger specimens they may, later on, be put into the next size. For the last shift, a compost of half loam and leaf-mould, and half rotten manure, may be employed; but the latter must be quite two years old, otherwise the proportion must be reduced. Rotten manure may be used in a pure state for *Vincas* with great success, provided it is several years old and has been turned over many times to purify it. I have found, indeed, that they make root more freely and grow much more rapidly in this rich soil than in any other; and the fact must never be lost sight of that they at all times require to be kept fully supplied with food and moisture. Should they, at any period of their growth, experience a dearth in this respect, the whole appearance of the plants at the flowering time will unmistakably show the effects of it. Plants of superior luxuriance may be obtained by planting them out, either in frames in a gentle bottom heat, or in a light house where a genial atmosphere can be maintained. Some

Salvia Bethelli.—The *Salvias* that bloom during autumn and winter are very effective and useful plants, the fault common in the case of most of them being their glowing red colours, which, when present in anything above a limited amount, are objected to by

Parisian growers cultivate them in this way, and the very best plants I ever saw in 4-in. pots were thus grown. Heat and atmospherical moisture are absolutely necessary for their proper development, and they should never lack for either until the blooms are expanding. Air must be freely admitted on fine days; but it should be taken off early, and the plants syringed and the house well damped down. As soon as the soil is fairly permeated with roots, weak manure water may be administered with benefit; it will strengthen them and put a gloss upon the foliage, and will improve the quality of the flowers. If the plants have been kept growing from the time of the first shift without check, they will by the middle of the summer have formed neat little bushes, and will be studded with their delicately pretty rosy and white flowers. They are then found very acceptable for the decoration of apartments and the conservatory, inasmuch as they form a complete contrast to most other blooming plants of that period of the year. If larger specimens are wished for some of the plants may be kept to be grown on the next year; and if sufficient space can be spared to grow them well, they will prove very strong and effective.

J. CORNHILL.

SHADING PLANT HOUSES AND FRAMES.

LIGHT and warmth are as necessary for plants as for human beings. Deficiency of heat causes a stagnation of the functions and a languid and feeble movement of the sap, whilst deprivation of light produces weakly and imperfect tissues. The effects of a cold, sunless summer are two well known this year to need description; we feel it in the late growth of our summer crops, and we equally experience its effects the ensuing season in an inferior and scanty fruit crop. It therefore behoves us in all that concerns the culture of plants to subject them, as far as is compatible with their respective natures, to the influence of the sun. As is well known, each plant demands of us a certain amount of special study, without which we cannot well hope to bring it to perfection. Let us take, for instance, two such families as Cactuses and Ferns; the one prefers an open dry position, the other delights in moist secluded situations; and yet the moisture-loving family must be supplied with a certain amount of light; it will not thrive, and will even die, if excluded from the sun's influence. It may be safely affirmed that it is never the sun's rays in themselves that injure vegetation; it is rather the aridity engendered by them, and which cannot well be counteracted in glass structures unless shade be afforded. In the case of Ferns, Orchids, &c., could we increase atmospheric moisture in proportion to the heat of the sun, we should have no need to screen our plants from its rays. This circumstance is so often lost sight of that shade is frequently applied on the principle that semi-obscurity is absolutely necessary to the welfare of the plants. Where this principle is carried to excess, the result is invariably drawn, weakly specimens, deficient in stamina, and quite unlike what they would be in a natural state. Many of our marsh and bog plants, the organism of which is of a somewhat fragile and delicate nature, bravely endure without flinching the sun's most ardent rays. The liberal and never-failing supply of moisture at the root, combined with the constant and abundant evaporation continually taking place around them, enables them to bear with impunity, and even enjoy, an amount of light and heat which would otherwise be extremely hurtful to them.

Certain plants which are classed as shade-loving are often grown in houses the glass of which is whitened over during the summer. It is often asserted that such treatment is rational, because the same plants are always found growing naturally where light is more or less intercepted by a stronger vegetation. This course of reasoning, although to a certain extent true, is misleading, inasmuch as the filtered rays of light which the undergrowth of a wood or forest receives are very different from the semi-obscurity afforded by a whitewashed glass roof. The most sceptical may convince himself of the truth of this assertion by visiting a wood where Ferns grow wild. They will neither be found in the open spots, nor will they be seen in the dense shade. They select, so to say, situations where they are in receipt of a considerable share of light, and oftentimes where, at some portion of the day, they are illuminated by the sun's rays. Then, again, it should be remembered that the interior of a shaded glass structure or a frame cannot be compared to the undergrowth of a forest.

The *Camellia* dislikes the full heat of the sun, but we are informed that it grows naturally where only the fiercest rays are excluded; and many kinds of Orchids are only to be found where they enjoy a considerable amount of sunlight. Shading may therefore be regarded as a necessary evil; its employment under certain circumstances is undoubtedly beneficial, and even necessary, but it may be so used as to exercise a very baneful effect upon any kind of vegetation submitted to it. In roomy lofty houses the evil effects of perpetual shade are felt to a much less extent than in the case of

small structures, healthy though many plants in the latter may seem. This is easily explained when the difference in the amount of light, which at all times exists between large and lofty and low and narrow structures, is borne in mind. A plant growing in a house 50 ft. high, the roof of which is continually shaded, will often grow as vigorously and develop as well as when placed in a small structure into which the light can pass unobstructed. Mosses and Ferns are types of shade-loving plants, which invariably shun the full blaze of the sun; yet I would not willingly deprive them at any period of their existence of a single ray of light, my experience inducing me to believe that they thrive in every way better when so placed that they never need to be shaded. A glass structure so situated that it catches the first gleams of the morning sun, and receives its departing rays, but which is quite sheltered from the noonday glare, will be found to perfectly fulfil the conditions necessary for the successful growth of this tribe of plants. They are there screened from excess of heat and aridity, whilst they enjoy the whole day through a maximum of light. The injurious effects of over-shading are seldom fully realised, as the plants subjected to it often display a fair amount of vigour. It is only at a later period of their career that the effects alluded to may be perceived, and then probably the true cause has been lost sight of. Maturation of the tissues is as necessary in the case of such a free-growing flowering plant as the *Primula* as it is for a fruit-bearing tree; and even with respect to tender stove plants, whether prized for their bloom or leaf beauty, we shall find that if unduly deprived of a certain amount of sunshine, they will never realise the expectations of the grower.

One of the most difficult things for a beginner to learn is the importance of minute attention in putting on and taking off shade. It appears to him that half an hour earlier in the morning and half an hour later in the evening can make but little difference. It is, however, often the loss or gain of this half hour which makes or mars the specimen. Let anyone calculate what half an hour a day amounts to in six months, and they will better appreciate the importance of this detail of plant culture. It is for this reason that frames having a north or east aspect are so useful in the summer season; one is enabled to expose them to the full light the whole day through. How much more freely and vigorously do seedling *Cinerarias*, *Primulas*, &c., grow when thus accommodated than if grown where shade has to be afforded during a considerable portion of the day. An east aspect is perhaps the very best that can be had for the summer growth of plants. They there get the first glimpse of the morning sun, and soon after the turn of the day the shade may be withdrawn, the plants watered, damped down, and freely exposed. Too much shade and moisture are prolific sources of mischief in stoves and Orchid houses. The interior of such places is often naturally dark, and when dense shade is given during the daytime, and the syringe freely used, both foliage and flowers are apt to be of a poor description.

The shading material employed should be thin enough to allow the diluted light to pass through it. A coarse canvas, or the French "Clarés," which are simply blinds made of narrow strips of lath so arranged that the light passes freely between them into the glass structure, are preferable to bast mats, which are far too dense for this purpose. A little practice and observation will enable any one so to arrange the time for putting on and taking off shade, that a considerable amount of sunlight may be admitted even to the most tender plants. If the house is well damped down, and the occupants sprinkled, they will bear exposure much earlier, and the solar heat and light, combined with the atmospheric moisture, will supply the conditions necessary to ensure free, healthy growth, and the wood and tissues will acquire that solidity which is indispensable for the production of handsome foliage and flowers. BY FLEET.

Lilies for Conservatory Decoration.—At this season of the year when hard-wooded plants are generally not available for decoration, Lilies, if plentiful, form most beautiful objects in the conservatory, where, if kept cool and shaded, their beauty will last for a long time. In a family, the members of which are all beautiful, it is perhaps ungracious to particularise; but the beautiful Japan Lily, *auratum*, and the different varieties of *laucifolium*, are extremely well adapted for cool-house culture. The compost which I like best is turfy loam, peat, rotten manure, and sand, potting in autumn as soon as the foliage has died down. The pots are then stored away in a cool shed, out of the reach of frost, until growth commences, when they are set in cold frames, and brought on according to the season at which it is desired to have them in flower. Top dressing with cow or sheep manure, and a little loam to encourage the development of surface roots, keeping them well supplied with water, and, above all, ripening off the foliage naturally, are the principal points in order to ensure success with this beautiful class of plants.—J. GROOM, *Linton*.

ROSES.

ROSES ON TREES.

THE annexed engraving represents a beautiful but not uncommon freak of Nature—a wild Rose self-planted in the heart of a pollard Ash. It is one of those freaks which may very well be imitated in the garden, not by planting the Rose in the heart of an old tree, but by planting it at the base and letting it ramble over the upper branches. I have here a very large and thick Box bush, in the centre of which there has been for many years an Ayrshire Rose. The long branches covered with flowers, and resting on the deep green

Wild Rose growing on a Pollard Ash in Orchardleigh Park, Somerset.

cushion, have a very beautiful effect. Other Roses may be used in the same way. The Musk Rose of Shakespeare and Bacon would be particularly well suited for this, and would climb up to a great height. *R. scandens* or *sempervirens*, *R. multiflora*, and perhaps some others, might be grown in the same way; and it would be worth while to experiment with other garden forms, such as *Aimée Vibert*, purple *Boursault*, &c. If grown against a tree of thin foliage, such as a *Robinia*, they would grow quicker and flower sooner; but this is not necessary, for even if grown near a thick-foliaged tree they will soon bring their branches to the outside for the light. But besides climbing Roses, there is another way in which Roses may be

combined with trees to great advantage, viz., by planting some of the taller-growing bushes at the base of the trees. These would grow from 6 ft. to 10 ft. high, and would flower well in such a position. For such a purpose the old Dutch Apple Rose (*R. villosa* var. *pomifera*) would be very suitable, and so would *R. cinnamomea*, *R. fraxinifolia*, *R. gallica*, *R. rubifolia*, and the common monthly China. And if growers would rear the perpetual and other Roses by autumnal cuttings instead of by budding, they might have hundreds and thousands of fine Roses which would do well planted in the woods and plantations.

H. N. ELLACOMBE.

Bilton.

BENNET'S PEDIGREE ROSES.

HAVING heard a good deal concerning the entirely new strain of Roses raised by Mr. Bennet, of Salisbury, and knowing that Messrs. Fisher, Holmes, & Co., of the Handsworth Nurseries, Sheffield, had secured a large stock of these, I sought for and had an opportunity of inspecting them a few days ago, and also of learning some particulars regarding their history, &c., which I am sure will be interesting to all lovers of Roses. In originating the new race of "Pedigree Seedling Roses," Mr. Bennet has most decidedly stolen a march on the older Rosarians, and one is not surprised to learn that there is a disposition in some quarters to underrate his productions; but I am mistaken if the Pedigree Roses do not take a foremost place in our gardens, and that, too, in a short time. Mr. Bennet, it may just be explained, is as much or more a farmer than a gardener, and, seeing the wonderful improvements made year by year in the cross-breeding of stock, he determined to make an attempt to apply the same rules to Rose breeding, and so far his new Roses are the result. From an intimate acquaintance with the history of the Rose and what had been done both at home and in France in raising new varieties, Mr. Bennet judged that no systematic attempt at cross-breeding by manual fecundation had been attempted, and in this direction he saw that he had scope. He therefore set about crossing Tea Roses with Hybrid Perpetuals, and succeeded completely, after encountering not a few difficulties, and the result of his labours up till the present time are nine new Roses possessing the vigorous constitution of the Hybrid Perpetual and a perpetual blooming habit never possessed by the latter, and otherwise totally different in type from any Roses hitherto raised. Mr. Bennet's object was to produce yellow and white Hybrid Perpetuals and crimson and high-coloured Teas, and in this he claims to have succeeded.

I append the names of the nine new sorts and the names of their parents in each case: Beauty of Stapleford, the produce of alba rosea crossed with Countess of Oxford, pink and rose. Duke of Connaught, the result of crossing President with Louis Van Houtte, deep velvety crimson and red; full. Duchess of Connaught, raised from President crossed with Duchesse de Vallambrosa, silvery-rose; distinct. Jean Sisley, the produce of President crossed with Emelie Hausburg, lilac and pink. Michael Saunders, raised from President crossed with Mme. Victor Verdier, bronzy-pink. Honourable George Bancroft, the result of crossing Madame de St. Joseph with Lord Macaulay, rosy-crimson shaded with purple. Pearl, raised from President crossed with Comtesse de Screnyi, flesh-white. Viscountess Fahnouth, also raised from President crossed with Moss Soupert et Notting, delicate pink-rose, very fine; this variety, as can be seen at a glance, indicates its parentage, the wood being only less prickly than that of a Moss Rose. Duchess of Westminster, the produce of President crossed with Marquise de Castellane; flowers large, fine form, bright cerise.

These descriptions, it may be mentioned, are abridged from the catalogue principally, but numbers of the varieties have already bloomed at Handsworth, and fully bear out the high character given them. Though little has been written about these Roses hitherto, they seem to have already excited much interest amongst Rosarians. All the varieties seemed well on the Dog Rose and on their own roots, and all are extremely hardy, having resisted 30° of frost in exposed situations. To their free and precocious flowering habit I can testify personally, for of the thousands that have been rapidly propagated at Handsworth within the last few weeks almost every plant had shown flowers and continued to do so where they had not been picked off. The whole stock is worked on the seedling Brier, and it is simply astonishing how Roses can be multiplied in this way. Private growers would perhaps hardly believe me if I were to tell them how many thousands of the Pedigree Roses had been raised from about four dozen plants received at the Handsworth Nurseries only in June last, and it says no little for the vitality of the new race that they can be multiplied at such a marvellous rate. All the plants were in 4-in. or 5-in. pots, and rooted and growing freely. The seedling Brier roots are simply chopped up into pieces like Seakale thongs and a Rose bud is inserted in each

piece, which is at once potted and placed in a frame; growth commences immediately, and before many days the plant is yielding buds in its turn for propagation. Summer grafting appears now to be practised on a far more extensive scale than formerly. I observed a number of the last new English Roses—Dr. Levell, H. Weir, Marquis of Salisbury, Eduard Morren (climbing), Countess of Rosebery, and others in the same frames—that had been winter-grafted, but could not compare in growth, vigour, or floriferousness with the summer-worked stock.

J. S. W.

ROSES ON THEIR OWN ROOTS.

THE three forms in which Roses are commonly grown in gardens have their several uses, and there will always be room for discussing their relative merits for particular purposes. But a general statement of the case may be made, and may be useful. For the production of flowers for exhibition on a strong deep soil the common Brier of the hedgerows is at once valuable and easy to manage. The rule of multiplying Roses with this stock is to enter buds at any height above ground that may suit the growth of the Brier or the wants of the cultivator. A 4-ft. Brier with two or three strong shoots at the top may be converted into a 4-ft. standard Rose by entering buds on two of the shoots, and cutting out the third; or to augment the chances of success, all three shoots may be budded and all the buds may be allowed to grow. For the production of useful garden Roses as well as of flowers thinned out for exhibition, the soil being stony or shallow, or otherwise not strong enough for the English Brier, the best stock is the Manetti. This is not well adapted for forming standard Roses, but makes good bushes, and in the process of budding the buds should be entered as near the roots as possible; in fact, the earth should be slightly scraped away from the base of the stock to enable the operator to insert the buds close down to the junction of the roots with the stem. When the buds have advanced and the Manetti or stock growth has been got rid of, the plants may be planted out a little deeper than they were in the budding bed, and in the course of time the Rose standing on Manetti roots will form roots of its own, and the original stock will die away, and thus by suitable arrangements Manetti Roses may be converted into Roses on their own roots. An important matter is the suppression of Manetti suckers, and therefore the beginner should as soon as possible become acquainted with the bluish-green leafage of this Italian Brier. When suckers that are evidently the growth of the named Roses rise, you may judge that your named varieties have rooted above the original stocks; therefore their suckers should not be suppressed, for it is one of the special properties of own-root Roses that they have the power of perpetually renewing themselves by the production of suckers from the roots. The Manetti is a charming wilderness and wild garden Rose, but its only use in the flower garden is to assist by means of its roots the free growth of named Roses, and it is to obtain this free growth in the bush form that we bud Roses on Manetti stocks.

Cuttings or Eyes.—The other and better way to obtain Roses on their own roots is to strike cuttings or eyes. It has been our practice for years to strike a lot of cuttings every year and grow them on in pots, flower them, and then plant them out. This practice is productive of a double pleasure. From April to the end of June the pits and houses supply quantities of little Rose trees that are pictures of health and freshness and that produce two or three flowers each, the flowers being of the most beautiful character, and the plants invaluable for lighting up the front line of the conservatory or to put upon the table or the sideboard, whence of course they are removed as soon as the flowers wane. Having served this purpose they have attained to a reasonable size for planting out. For all purposes, where the soil is of a kindly nature, Roses on their own roots are best; they make better groups than standards; they produce the finest exhibition flowers when suitably managed as to feeding and thinning; and when a great frost cuts off all the Roses—and many will remember that such things have happened—the Roses on their own roots rise again and re-establish themselves, which Brier Roses cannot do, because the Briers stand between the Roses and the ground. The reason why Roses on their own roots have this power of renewal is to be found in the fact that when frost kills the tops it does not usually touch the bottoms. The shoots are killed, but the roots remain unhurt; these roots have but to be left alone and they will throw up a quantity of strong suckers, and these branch and flower and become as good, and perhaps better, bushes than those originally planted. The time is at hand for striking cuttings and eyes of Roses. As the flowers wane the new growth will appear, and the cuttings should be prepared from the young shoots when they have become a little firm, but before they have hardened into real wood. To do the work well a good frame or pit is needed, and a few bell-glasses or common hand-lights. Indeed, the propagation by cuttings should be carried on at the same time as budding, so as to use up all

the shoots that are cut from which to obtain buds. When you take off a fine rod to get a few buds, the top of it, say five or six joints long, will make the best possible cutting. If the top is very soft cut it away, and prepare the cutting in the usual manner by a clean cut under the lowest joint, the leaf from that joint and the next joint above it to be removed. Then prepare a 2½-in. pot with a few small crocks, a mixture half sand and half leaf-mould, pressed in moderately. Into this the cutting is to be thrust till its base is hard upon the crocks, and a bit more compost to fill nearly to the rim, and another pressing to make it tight and firm. Give a good watering and put it into a cold frame with a bottom of coal ashes, and shut down close. Cover with a mat to prevent mischief from sunshine, and it will be strange if every one so dealt with does not make a promising plant; the latter should be shifted into 3-in. pots into proper Rose compost, and to be wintered in a pit or in a greenhouse. If your pits and frames are already overstocked, creep in among the Currant bushes, level a piece of ground in a shady place, pack the pots together in circles, and put a bell-glass or a hand-light over each lot; give air by degrees, and watch that their new shoots are not attacked by vermin, and you will soon see that there is no magic or mystery in propagating Roses by the million.

Bud-striking.—But a still better and even a more interesting way is to use buds instead of cuttings. Take a shoot, such as would be chosen as a scion for budding. Have some shallow pans prepared with crocks, leaf-mould, and sand, and one inch of pure sand on the top. Better still, use turfy peat, with the same inch of sand on the top. Cut away the best buds, in the same way as if they were to be used for budding, but let the wood remain and let the leaf remain. Plant each of these shield buds upwards, leaf complete, bark just covered, so that the bud stands up very firmly. Waste no time; as soon as the pot is filled, so that the leaves just touch all over, give a good sprinkling of water, put on the bell-glass, and go on again. The tops of the shoots may be put in quite closely together as cuttings, with the two lowest leaves removed, and the wood cut clean under a joint. Put them in shallow pans, put on the bell-glasses, and very few will fail. Buds treated in this way start in the same manner as Grape Vine eyes, only Grape Vine eyes have no leaves to help them. Pot them singly into 2½-in. pots as soon as they begin to put out whiteroots from the callus, or you may even pot them as soon as the callus has become definite and firm. Shift none from the first potting till the roots begin to peep out through the crocks, and not even then if the season is far gone, unless you can give them a shelf in a warm house. It is best to winter these in a pit or greenhouse. They make beautiful plants, and can be grown to any shape or any size of which the variety is capable. The last lot which I struck from eyes in this way were put in an old frame on a great heap of waste Fern and Moss, full in the sun. A mat was kept over them all day, and removed at sunset. A week afterwards, the light was tilted to give a little air, and they came wonderfully quick and strong, the Fern acting as a hot-bed. Out of twenty-two pans covered with bell-glasses all succeeded but one, and that one the ants got into and filled the bell-glass with the debris of their mining operations, burying the buds six inches deep.

Autumn Cuttings.—Instead of a few coddled, dwindled specimens of struck cuttings of the Rose that so often serve to satisfy the amateur gardener, who has hitherto only attempted the propagation in pots and in heat, let me briefly tell him how to secure plants by the hundred, or even thousand, if he please, with as much certainty as he produces his hundreds of Tom Thumb Pelargoniums. In the latter part of September or first week of October go over the Rose beds, and cut off all the straggling shoots; cut them up into cuttings (excepting the soft points) about 6 in. in length, or more if the eyes are far apart. Having previously dug and well broken a piece of ground, and put upon the surface a good dressing of sand, which slightly stir in, tread the ground evenly all over, and smooth the surface. Then take a spade, and begin at one end to open a slight trench; then insert a row of the cuttings, about 3 in. apart, after which close the soil closely upon them; then open a second row at about 6 in. from the first, and proceed as before, and so on until all are planted. By autumn of the next year they will be good plants, if occasionally stopped when growing freely during the summer. I knew a nurseryman who used to put in his winter prunings of Roses in this way, and was content if he got one in three or four to grow. Had he done as now recommended he might have made sure of nearly all. He waited till the growth had quite ceased, and hence his partial failure; whereas if the cuttings are made whilst the sap is still in motion, a callosity is formed before winter, and the cutting is able in consequence to resist the inroad of wet during winter, and is thus preserved from rotting. In October a few years ago, I inserted a quantity of short cuttings of Géant des Batailles, Jules Margottin, General Jacqueminot, and others of the most useful Roses, in a bed of leaf-mould in a pit from which the lights were removed; they had no water, and, in fact, no attention, except that

at the end of November the lights were put on and kept on till the bright weather of April compelled their removal. The pit was then full of good healthy plants, nearly all showing bloom buds. The best were lifted with a trowel, potted into 4½-in. pots in rich soil, half rotten manure and half turfy loam; they were then placed in the greenhouse, and on May 8 the first bloom opened, and a few days afterwards they were all in bloom and with their bright clean foliage made a charming spectacle. This I imagine is the simplest of all methods of propagating Roses on their own roots.—*Gardener's Magazine.*

TREES, SHRUBS, AND WOODLANDS.

FORESTS OF CENTRAL NEVADA AND ADJACENT REGIONS.

By CHAS. S. SARGENT.

To the traveller crossing the Great Basin by the line of the Pacific Railroad the country will appear almost as destitute of trees as the great plateau over which he has passed in approaching the Rocky Mountains from the east. This first impression will disappear, however, should he penetrate farther south, and ascend some of the low mountain ranges, which, with a general north-and-south trend, everywhere cut up this elevated interior region into long, narrow valleys. As compared with our Atlantic forests, or those still nobler ones which, farther to the west, owe their existence to the influence of the Pacific, the forests which clothe, with a scanty and stunted vegetation, the mountain slopes of Nevada are miserably poor in extent, productiveness, and especially in the number of species of which they are composed. Actually they are of immense value. For scanty as they are, they regulate and protect the rare and uncertain streams on which the agriculture of Nevada depends, and furnish a large population with fuel and lumber; a population, too, which, while consuming and wasting enormously its forests in vast mining operations, is practically cut off, by its isolation and the cost of transportation, from outside supply.

A hurried journey made in September last, undertaken for the purpose of studying *in situ* the trees of the Great Basin, and of introducing into cultivation some of the peculiar plants of that region, took me to the great mining centre of Eureka, and then through Dry and Fish-spring valleys seventy-five miles further south-west into the Monitor Range, to the point where its highest peak, Table Mountain, reaches an elevation of 11,200 ft., and offered an excellent opportunity to examine the timber supply of that central portion of Nevada.

The forests of this portion of the State are composed of but seven species. Of these, two, the Red Cedar (*Juniperus virginiana*, L.) and the Aspen (*Populus tremuloides*, Michx.) extend across the continent; two, *Pinus Balfouriana* (Murr.) and *Pinus flexilis* (James), extend along the mountain ranges from the Rocky Mountains of Colorado to Mount Shasta in California; two, *Pinus monophylla* (Torr.) and *Juniperus californica* (Carrière) var. *utahensis* (Engelm.) are endemic to the Great Basin; while *Cercocarpus ledifolius* (Nutt.), although occurring as a shrub both in the Rocky Mountains and in California, only here becomes a valuable tree.

Neither the Red Cedar nor the Aspen need be considered here. A single small plant of the former was noticed; and it is evidently so rare throughout this region that it adds but little to the value of its forests. The Aspen borders all the mountain streams above 8000 ft. elevation, but, rarely surpassing 15 ft. in height and a few inches in diameter, is practically without value for its products. Further east in the Wahsatch Mountains, this species is sometimes seen with stems 2 ft. through; and it is largely used by the Mormons, who consider it valuable for flooring, turnery, &c.

Juniperus californica var. *utahensis* is the most common and the most widely distributed of the trees of this region. It is found at lower elevations than any other tree, and alone descends into the valleys, where, at elevation of 5000 ft., it is often abundant, but less so than on the mountain sides, over which it spreads up to 8000 ft. elevation. It is a low, bushy tree, branching from the ground, with a stout trunk which rarely exceeds 2 ft. in diameter; short and very stout branchlets, and thick, shreddy bark. The wood, which is moderately hard, pale coloured, and slightly aromatic, furnishes the common and cheapest fuel both for domestic use and for generating steam on the railroads and at the mines. The typical *Juniperus californica* belongs to the Californian coast range, and the variety extends over the whole of the southern portion of the Great Basin. In fruit this species will be readily distinguished by its dry one-seeded berry, the great thickness of the stony coating of the seeds, and from all other Junipers (as pointed out by Dr. Engelmann) by its 4 to 6 cotyledonous embryo. Without fruit it may be easily confounded with *Juniperus occidentalis* (Hook.), which species, however, has not been detected in Central Nevada. Like all the trees of the Great Basin, this Juniper is of exceedingly slow growth. A specimen before me 4½ in. in diameter shows 105 annual layers of growth, or an annual average increase of nearly one-fiftieth of an inch.

Growing with this Juniper, above 6000 ft. elevation, and extending rather higher up the mountains, is *Pinus monophylla* (Torr.), the Nut Pine of Nevada and Eastern California, but not to be confounded with an allied species, also bearing edible seeds, *Pinus edulis* (Engelm.), found from Colorado to New Mexico and Arizona. *Pinus monophylla* is a small tree, 10 ft. to 20 ft. high, with reddish scaly bark, and is easily distinguished from other North American Pines by its solitary, glaucous, terete leaves (very rarely in pairs, and then semi-cylindrical). The wood is white, soft, light, and very resinous; it is more highly prized for making charcoal than that of any tree of this region. In slowness of growth *Pinus monophylla* does not essentially differ from the Juniper with which it is associated. A specimen that I have examined, from the locality which furnished the specimen of Juniper referred to above, is 5½ in. in diameter, and shows 113 annual layers of growth. The immense crops of large and delicately-flavoured seeds produced by this tree supply, as is well known, to the Indian tribes of the Great Basin their most important article of food. The value of this crop and the excellent quality of the wood for charcoal make this tree, in a mining region entirely destitute of coal, its most valuable vegetable production. The introduction of *Pinus monophylla* into the south of Europe as a subject for forest planting is worthy of consideration; it might flourish there on those dry and exposed hill sides which have been found so difficult to satisfactorily re-cover with any European tree. Its strictly pyramidal habit while young—a habit which it entirely loses with age—and the pleasing glaucous tints of its foliage commend this species to the lovers of ornamental Conifers.

*Pinus Balfouriana** was only met with on Prospect Mountain, near Eureka, at an elevation of 7500 ft., to the summit 8000 ft. Formerly the whole summit of this mountain was very generally covered with this species; but, with very few exceptions, the trees have all been cut to supply the mines with timbering, for which purpose the strong and very close-grained tough wood of this species is preferred to that of

* With the insufficient material at my disposal I cannot satisfactorily separate *Pinus aristata* (Engelmann) from Murray's *P. Balfouriana*, the older name, and founded on Californian specimens. *Pinus aristata* is an Alpine plant discovered by Parry many years later in the Rocky Mountains of Colorado.

any other Nevada tree. The specimens seen were from 15 ft to 30 ft. high, with trunks often 2 ft. in diameter, pyramidal in outline, their lower branches still remaining, so that at a little distance they might readily be mistaken for Spruces. The bark, like the wood, is reddish in colour, very thick, and deeply furrowed; that of the branches smooth and quite white. The short, falcate, adpressed leaves persist for years, forming tufts of foliage 1 ft. or more long at the ends of the naked branches; and this peculiarity has suggested to the lumbermen of the region the name of "Fox Tail Pine" for this species. *Pinus Balfouriana*, should it be found to retain in cultivation the peculiarities which characterise it on the mountains of Nevada, will be one of the most striking and interesting of the genus for ornamental planting.

Pinus flexilis, the Nevada representative of the Eastern White and the Californian Sugar Pine, is the largest and the most valuable timber tree of the central portion of the Great Basin. I found large tracts of it on the Monitor Range from 8000 ft. up to 10,000 ft. elevation; and further to the north-east it gives their names to White Pine District, White Pine Range, &c. On the Monitor Range specimens from 50 ft. to 60 ft. high, and from 2½ ft. to 4 ft. in diameter were not unfrequent, the trees becoming smaller as the elevation increased, until at 10,000 ft. they were little more than prostrate bushes 1 ft. or 2 ft. high. The fact that the finest specimens were found on the banks of the mountain streams, associated with *Populus tremuloides*, indicates that this species is more dependent on moisture than the other Nevada Conifers. It is the only tree of this region which is sawed into lumber. The wood is soft, white, and, although not free from knots, is of fair quality, and about intermediate between Eastern White Pine and Sugar Pine.

Cercocarpus ledifolius, with *Populus tremuloides*, the only non-coniferous tree of this region, here attains its largest size and greatest age. It is common at from 6000 ft. to 8000 ft. elevation, and, next to the Juniper and the Nut Pine, is the most common of Central Nevada trees. It is a small tree from 10 ft. to 30 ft. high, with small evergreen leaves and brown scaly bark, in habit and general appearance not unlike a stunted Apple tree. The wood of this tree, which is of a bright mahogany colour, and susceptible of a beautiful polish, is exceedingly hard, heavy, and close-grained, but very brittle, and so liable to "heart shake" and difficult to work as to be useless in the arts. It is, however, sometimes employed for the bearings of machinery, where it is found to wear as well as metal; but it is as fuel that "Mountain Mahogany" (the name by which, owing to the colour of its wood, *Cercocarpus* is universally known) has no North American equal. We are in the habit of considering that our Eastern Hickories produce the best fuel. The specific gravity of dry Hickory is but .832, while that of *Cercocarpus* is 1.117, so that, weight being the best test, as fuel it is worth 30 per cent. more than Hickory. The amount of ash, too, left after burning *Cercocarpus* is only 52-100ths of 1 per cent. of the dry wood consumed, while that of Hickory is 81-100ths of 1 per cent.; 3-10ths per cent. more. *Cercocarpus* is probably the only North American wood which is heavier than water; and among the tropical woods employed in the arts and described by Haslett, but six equal or surpass it, the most conspicuous being the West Indian *Lignum Vitæ* (*Guaicum*) with a specific gravity of 1.248. As was to be expected the growth of *Cercocarpus* was found to be exceedingly slow. An examination of several specimens from 100 to 200 years old shows an average annual increase of wood only 1-6th of

an inch in thickness. The largest specimen of this tree was seen on Prospect Mountain near Eureka, in New York Canon, at an elevation of 7000 ft. It was a low, much branched tree, about 20 ft. high, with a trunk rising 6 ft. to the first branches. At 3 ft. from the ground it had a girth of 7 ft. 5 in. If we suppose that its average growth had been as rapid as that of the younger specimens examined, this tree would have been 890 years old. It was probably much older. The rate of growth of trees is, after a certain age, in inverse ratio to their age, and it is perhaps permissible to suppose that the seed which produced this little tree had already germinated when the oldest living *Sequoia* on the continent was still a vigorous sapling with its bi-centennial anniversary still before it.

Two shrubby plants of this region may be mentioned, which from their beauty are especially worthy of introduction to cultivation—*Cowania mexicana* (Don.), a large Rosaceous shrub, nearly allied to *Cercocarpus*, with elegant pinnatifidly-lobed leaves and large and very abundant yellow flowers; and a large, shrubby *Spiræa* (*S. Millefolium*, Torr.), with the foliage of *Chamaebatia*, but a larger and more striking plant, and, perhaps, the most elegant of the genus.

It will have been seen that the forests of Nevada, consisting of a few species adapted to struggle with adverse conditions of soil and climate, are of immense age, and that the dwarfed and scattered individuals which compose them reach maturity only after centuries of exceedingly slow growth. On this account, and because, if once destroyed, the want of moisture will for ever prevent their restoration, either naturally or by the hand of man, public attention should be turned to the importance of preserving, before it is too late, some portions of these forests. Large areas of forest-covered mountain ranges are still held by the General Government, and in view of the vast importance of their remaining wooded to serve as reservoirs of moisture, on the existence of which the future of this region must depend, it would seem wise and not perhaps altogether impracticable to check or at least to regulate the terrible destruction of forest, which follows, both on public and private domain, every new discovery of the precious metals.

A comparison of the arborescent vegetation of Nevada with that of the region lying directly east and west of the Great Basin may be interesting. Such a comparison will serve to more clearly demonstrate the remarkable poverty of the Nevada forests. It will afford, too, another illustration of the relation of the moisture to forest distribution, especially with reference to the multiplication of species, which will be found to increase or diminish as the rain-fall is more or less abundant and more or less equally distributed.

In the territory between the 41st and 37th parallels of latitude, and extending from the eastern base of the Rocky Mountains to the foot of the western slope of the Sierra Nevada, are three distinct belts of arborescent vegetation.* Beginning at the east there is: 1, the Rocky Mountain region, including, besides the main range, the Uinta and the Wahsatch, and embracing Colorado and the eastern half of Utah; 2, the Nevada region, extending from the western base of the Wahsatch to the eastern base of the Sierra Nevada, and embracing the western half of Utah and the whole of Nevada with the exception of the extreme northern and southern portions of the State; 3, the Sierra Nevada region.

In the Rocky Mountain region, to which, in spite of its mid-continental position, considerable moisture is attracted by high peaks which everywhere dominate it, there are twenty-

* For the purpose of the present comparison not only trees but all frutescent plants which may be expected to exceed 4 ft. in height, and therefore as undergrowth to form an important element in the forest, will be included.

five trees and forty-eight shrubs, in all seventy-three species. In the Nevada region, where, owing to its isolated position between high mountain ranges, the rain-fall is small and very unequally distributed, the number of species is reduced nearly one-half—to thirty-eight; ten trees and twenty-eight shrubs. In the Sierra Nevada region, to which the Pacific contributes a large, although unequally distributed, snow and rainfall, the number of species is increased to eighty-nine; of these thirty-five are trees,† or three and a half times more than occur in the adjoining Nevada region, and a third more than are found in the Rocky Mountain region; and fifty-four are shrubs, or double the number of the Nevada region.

The following table shows the arborescent‡ and frutescent species, so far as they are now known, which occur in these three regions:—

*Torreya californica**
*Juniperus occidentalis**

89 species
51 genera
31 timber trees
4 small trees
54 shrubs

The following species, fourteen in number, are common to the three regions:—

<i>Acer glabrum</i>	<i>Rhus aromatica</i> var.	<i>Ribes aureum</i>
<i>Prunus demissa</i>	<i>Spiraea discolor</i> var.	<i>Cornus pubescens</i>
<i>Cercocarpus ledifolius</i>	<i>Amelanchier alnifolia</i>	<i>Sambucus glauca</i>
<i>Ribes cereum</i>		<i>Lonicera involucrata</i>
		<i>Populus tremuloides</i>
		<i>Pinus flexilis</i>
		<i>Pinus Balfouriana</i>

The following species, twelve in number, are, in addition to those named above, common to the Rocky Mountain and Sierra Nevada regions:—

<i>Rhamnus californica</i>	<i>Alnus incana</i>
<i>Neillia opulifolia</i>	<i>Pinus contorta</i>
<i>Cercocarpus parvifolius</i>	<i>Pinus ponderosa</i>
<i>Pyrus sambucifolia</i>	<i>Abies concolor</i>
<i>Ribes leptanthum</i>	<i>Pseudotsuga Douglasi</i>
<i>Sambucus racemosa</i>	<i>Juniperus occidentalis</i>

All the species of the Nevada region extend into the Rocky Mountain region, with the exception of the following ten species:—

<i>Berberis Fremonti</i>	<i>Shepherdia rotundifolia</i>
<i>Prunus Andersoni</i>	<i>Spirostachys occidentalis</i>
<i>Spiraea millefolium</i>	<i>Populus trichocarpa</i>
<i>Rosa californica</i> var.	<i>Pinus monophylla</i>
<i>Fraxinus anomala</i>	<i>Juniperus californica</i> var.†

† *Pinus monophylla* (Torr.), although it has found a foothold on the eastern flank of the Sierra Nevada, is not included among the trees of this region. This species, as well as *Artemisia tridentata*, are so peculiar to the Nevada region that they cannot be properly considered a part of the flora of the Sierra Nevada.

‡ Species which become large enough to be of economic value as timber trees are designated by a (*).

Populus trichocarpa is the only species (with possibly the two Willows) of the Nevada Region, which, in addition to the fourteen species common to the three Regions, extends into the Sierra Nevada. So that fifteen species of the Nevada Region reach the Sierra Nevada Region, while twenty-eight species extend into the Rocky Mountain Region, leaving but ten species peculiar to the Nevada Region. Of these *Fraxinus anomala* and *Shepherdia rotundifolia* are endemic; the other eight species extending south into Arizona.

The following genera common to the Sierra Nevada and Atlantic forests have no representatives in the mid-continental Flora:—

<i>Calycanthus</i>	<i>Leucothoë</i>	<i>Tsuga</i>
<i>Esculus</i>	<i>Rhododendron</i>	<i>Torreya</i>
<i>Cercis</i>	<i>Styrax</i>	
<i>Cephalanthus</i>	<i>Myrica</i>	

The following genera of the Sierra Nevada Region have no Eastern representatives:—

<i>Fremontia</i>	<i>Garrya</i>	<i>Castanopsis</i>
<i>Adenostoma</i>	<i>Eriodictyon</i>	<i>Sequoia</i>
<i>Heteromeles</i>	<i>Umbellularia</i>	<i>Libocedrus</i>
<i>Carpenteria</i>		

The absence of arborescent and frutescent Leguminosæ from the three Regions, where herbaceous genera of this order are so largely represented, is remarkable, especially as they abound farther south in New Mexico and Arizona. In the Rocky Mountain Region there is a single representative of this order, a *Robinia* nearly allied to those of the Eastern States; in the Nevada Region there is a single frutescent Leguminosa, and in the Sierra Nevada but one species, a large shrubby *Cercis*. On the contrary, the number of genera of frutescent Rosaceæ, many of them endemic and monotypic, is very large in proportion to other Angiosperms. In the Rocky Mountain Region there are thirteen genera with nineteen species; in the Nevada Region seven genera with ten species; in the Sierra Nevada Region eleven genera with thirteen species; in all, fourteen genera with twenty-eight species. In all the United States east of the Mississippi River there are but ten woody Rosaceous genera, all represented in our three Regions with the exception of the Southern *Chrysobalanus* and *Neviusia*.

The comparison of these three Regions with reference to the distribution of the Oaks will show how dependent these are on moisture. Oaks abound in both the Atlantic and Pacific forests, while in the Rocky Mountain Region there is but a single, exceedingly polymorphous species, which does not reach the Nevada Region, where no Oak is known; nor has this genus, so far as I know, any foothold on the dry eastern slope of the Sierra Nevada. A few insignificant species extend, however, along the mountains of Arizona and New Mexico, where the precipitation of moisture is more regularly distributed than farther north, and serve to connect the Oaks of the Pacific with those of the Atlantic forests.

The absence of *Pinus ponderosa* from the Nevada Region is remarkable. This species abounds in all the Rocky Mountain Region, and extends through New Mexico and Arizona to the Sierra Nevada, where, on the dry eastern slope, it constitutes in some of its forms fully three-quarters of the forests. It might, therefore, be naturally looked for on some of the higher mountains of Central Nevada, where, however, it has not yet been seen.

Pseudotsuga Douglasi, which also abounds in the Rocky Mountain Region, and on the higher mountains of New Mexico and Arizona, does not enter the Nevada Region. This is less remarkable, perhaps, than the absence of *Pinus ponderosa*, as this tree does not appear, in any numbers at least, on the eastern slope of the Sierras, and only reaches its noblest development in the humid climate of the north-west coast.

Juniperus virginiana, the most widely distributed of North American trees, ranges from the St. Lawrence River to Florida, and from the Atlantic to the Northern Pacific. It does not, however, enter the Sierra Nevada Region, and is extremely rare in Nevada.—“American Journal of Science and Art.”

WOODLAND WORK FOR AUGUST.

THE completion of all work connected with the usual spring fall of timber, such as the allotment, sale, and removal both of the timber itself and what is commonly called the “lop and crop,” should now leave the forester free to finish his summer pruning, and to make every preparation for the autumn planting. He should also avail himself of dry weather to cart to the saw-mill all timber intended to be converted for buildings and repairs. By mowing the wood-rides early, and brushing up their sides and making a general clearance at once, the game driven in by the operations in the harvest fields will afterwards remain in undisturbed possession of the necessary cover until the shooting season commences—a gain to the sportsman which it is almost impossible to overrate.

Besides the usual trenching and hoeing, or pitting, for large trees, it will now be necessary to break up with the pick or mattock the spots in which smaller plants are to be hereafter inserted by notching. Pruning operations should finish up with such trees as the Birch, Maple, and the Gean, none of which should be touched until shortly before the fall of their leaves. The beauty of the last-named tree, both on account of its flowers in spring, its fruit in summer, and the deep red and yellow colours of its foliage in autumn, renders it worthy of more attention than it generally receives at the hand of the forester.

In ornamental plantations prepare for the removal of the larger evergreens, an operation which may be commenced after the middle of the month, and continued, during suitable weather, into the early part of October. Those first removed may require watering and mulching, and perhaps shading. Plant out *Arbutus*, *Laurustinus*, *Rhododendrons*, and with both these and the Firs take care to raise during the day no more than can be replanted, and keep them out of the ground as short a time as possible; also secure a good ball of earth around their roots. Continue to bud *Thorns*, *Hollies*, and *Chestnuts*, and to tread-up spring-planted trees which have become rocked and loosened by the wind. Make preparations for layering by cutting and preparing pegs, loosening the soil around the stools, and cutting away all superfluous shoots, so that when the operation is performed all the strength of the stool may be directed to the new layers, which will speedily take root.

In the nursery plant out cuttings of *Laurel*, *Holly*, *Bay*, *Box*, *Yew*, *Privet*; also two years' seedling *Hollies*, taking care not to break off the small root-fibres, and remove *Laurels*, *Privets*, &c., which have been raised from cuttings of a former season. Cuttings of this year's shoots, with an addition of about 1 in. of last year's growth, may generally be depended on; but where the soil is heavy, an addition of a little sharp sand will be found useful. Moist, but not wet situations, should be chosen, and the land should be well worked and lightly manured.

August is generally found a good month for new turfing old lawns, or sowing them down with Grass seeds. The following mixture has been found to answer the purpose well upon medium soils: *Golden or Yellow Oat Grass*, *Sheep's Fescue*, *Wood Meadow*, *Evergreen Meadow*, *Rough-stalked Meadow*, and *Trefoil*, 2 lb. of each; *Hard Fescue*, 4 lb.; *White Clover*, 7 lb.; *Crested Dog's-tail*, 9 lb.; *common Rye*, 10 lb.; in all, 42 lb.

Pay attention to broken branches in parks and on the margins of woodlands, and also watch tillers in exposed falls of the last winter. Look well after trees which have been grafted or budded during the present season, loosening bandages, and removing shoots from the old stock. Trim hedges of all kinds, and keep them free of weeds. Tree guards should be kept in good order, so as to keep back sheep as well as horses and cattle. During dry and warm weather paint or tar gates, stiles, posts, and fencing of all kinds.

Pluckley, Kent.

A. J. BURROWS.

Hedges.—There is one thing at the Handsworth Nurseries with which no practical gardener can fail to be struck, and that is the tall *Beech* and *Quick* hedges planted throughout the grounds for protection from cold winds, the situation being high and exposed. These hedges are exceedingly well kept, being quite close and impervious to the bottom, though long planted, and showing what can be made of a hedge by good management. The *Quick* hedges are about 10 ft. or 11 ft. high—as high as a garden wall, and some of the *Beech* ones are much higher, perhaps 14 ft. The ground is

thrown into large enclosures by these hedges, and in these all the tender shrubs are raised and nursed. I have seen many a private garden that would have been much benefited by such protection in the absence of walls or other shelter. The Beech is the best of the two subjects, however, as it requires less keeping, grows faster, and retains its dead leaves during the winter, thereby adding much to its sheltering power.—J. S. W.

NOTES OF THE WEEK.

Theropogon pallidus.—We have received specimens of this charming plant from Mr. Howard, of Southgate, who informs us that he has received an importation of it from India. It grows from 6 in. to 1 ft. high, and has Grassy foliage similar to that of an Ophiopogon. Its flowers much resemble those of the Lily of the Valley, but are rather larger and pink in colour. As it flowers later than the Lily of the Valley, it forms a capital substitute for the rose-coloured variety, though an absence of scent doubtless detracts from its merits. It is presumably quite hardy in this country, as it inhabits high elevations in the Himalayas, in Sikkim often rising to 10,000 ft. It is found growing on Mossy rocks, the bases of old trees, &c., where the roots spread superficially in the loose soil.

A New Lily (*Lilium auratum eruentum*).—This fine Lily is now finely in flower in Mr. Bull's nursery. In habit, and in the size and form of the blossoms, it is identical with the typical form. The ground colour of the flower is pure white, with a broad, deep crimson band down the centre of each petal, and the whole flower is copiously spotted with raised papillæ of the same colour. It affords a striking contrast to the ordinary form of *L. auratum*, and more particularly to the variety *virginale*, which has flowers spotlessly white, their chaste beauty being only marred by the golden stripes through the petals; this beautiful Lily is also finely in flower in this nursery. It would be interesting to trace the origin of *eruentum*, for, though it was imported direct from Japan, it probably, like its beautiful congener, *L. Parkmanni*, possesses some of the characteristics of *L. speciosum*.

Angraecum citratum.—This charming little species is now in full beauty in the Orchid houses in the Exotic Nursery, Chelsea. It is dwarf in habit, and has leaves arranged in two rows. The flower-spikes are from 6 in. to 9 in. long, and are produced from the axils of the leaves. The flowers measure about $\frac{1}{2}$ in. across, and have a spur about 1 in. long. The colour is a soft creamy white, with a mauve-coloured centre. They emit an agreeable perfume, a circumstance which much enhances their beauty. It is one of the most desirable of the small-growing Orchids for growing in a stove temperature. Like all the species of *Angraecum* it is a native of Africa, from whence it has recently been successfully imported in quantity by Messrs. Veitch.

The Scarlet Stonecrop (*Sedum sempervivoides*).—This fine hardy succulent is one of the brightest ornaments on the rockeries at Kew. Its brilliant scarlet Roehia-like blossoms fringed with yellow-tipped stamens, and borne on densely branched stems, are very striking. The habit, too, is remarkable, being so unlike that of the other kinds of Stonecrop. It has thick pointed fleshy leaves, arranged in a rosette-like tuft, as in the common House-leek. It is perfectly hardy, and will thrive on any well-drained rockery. It is a native of Asia Minor, Caucasus, &c., and is known also in gardens under the erroneous name of *Umbilicus Sempervivum*, which is a quite distinct plant, and belongs to another genus.

Rosa Brunoni.—Near the Cactus house at Kew a large bush of this charming Nepalese Rose forms a highly attractive object. It is rambling over the shrubs and trees near it, and is covered with its star-like, sweet-scented, white blossoms. It is one of the most suitable kinds for training on pillars or over arches, and is a capital Rose for the wild garden, where it can ramble about undisturbed. As a standard, too, it makes a handsome specimen, as may be seen by the fine plant of it in the arboretum at Kew, which is also a mass of bloom at the present time.

Lilium scintillans.—This is the name given to a remarkable variety of *L. elegans*, which we saw in Mr. Bull's nursery a few days ago. It is a dwarf form with flowers of moderate size, and quaintly mottled with various shades of red and orange, quite unlike those of ordinary varieties. It is in the open air, associated with a large number of other kinds, which now make a fine display. Amongst the latter we noticed *L. Krameri*, Browni, most of the American kinds such as *L. pardalinum*, *canadense*, &c., the beautiful *L. eximium*, and the many forms of *L. elegans*, and notably the blood-red coloured form *L. atrosanguineum*. Along with these were also *L. Leichtlini*, *Martagon album*, *neilgherrense*, and the beautiful unspotted variety of *L. auratum* (*virginale*), with its pure white flowers

marked only with a golden stripe down the centre of each segment of the corolla.

Heavy Crop of Peaches.—Mr. Cowburn, of Sunbury Park, has sent us some excellent Peaches and Nectarines, which, he informs us, he has gathered from two trees that are bearing respectively 330 and 250 dozen fruits, which is at the rate of ten fruits to each square foot.

Iris Darius.—We omitted to mention last week that this beautiful Iris, of which we gave a coloured illustration, was raised in Mr. Parker's nursery at Tooting by Mr. Brown. It is one of the most desirable of Irises, being neat in habit, an abundant bloomer, and an effective plant grown in clumps and masses in the mixed border, margin of shrubberies, &c.

Importations of Dutch Bulbs.—These, we are informed by the Committee of the Society of Bulb and Seed Merchants at Haarlem, will be later this year than usual, the unfavourable season having caused delay in drying the bulbs. Purchasers must therefore allow their bulb merchants the necessary time for the delivery of the bulbs in a dry condition.

A New Holly.—Mr. Marnock sends us the leaves of a very fine Holly, which is about to be sent out by Messrs. Fisher, Holmes, & Co., of Sheffield. It is a green kind with very large leathery leaves. The same firm has also a Golden Taxus *adpressa*, which promises to be a welcome shrub, being well variegated like the Golden Yew, but of course retaining the habit of the green *adpressa*.

The Fringed Grass of Parnassus (*Parnassia fimbriata*).—We saw this rare bog plant in flower a few days ago at the Hale Farm Nurseries. Its kidney-shaped root leaves are somewhat like those of the Asarum-leaved kind (*P. asarifolia*), but its flower-stems are taller, and it has beautifully fringed white petals. It is growing in an artificial bog near the rock garden along with other moisture-loving plants.

Mucuna imbricata.—This handsome stove climber is now finely in flower in the Palm-house at Kew, where it forms a highly attractive object. Its dense clusters of deep purple Pea-like blossoms hang from the slender branches like bunches of Grapes. Though it is such a desirable decorative plant, it is too rank in growth to admit of its being grown in any but large houses. It is a native of Sylhet and by no means new, having been introduced to our stoves many years ago.

The Japanese Hyssop-leaved Dracocephalum (*D. Ruyschiana*, var. *japonicum*).—The desirability of planting hardy perennials in masses is well shown in Messrs. Veitch & Sons' nursery at Coombe Wood, where this plant is now in full bloom, and forms a highly attractive feature. This Japanese variety differs but little from the original, though it is apparently more robust, and develops larger flowers of a deeper purple hue. It is a fine border flower, perfectly hardy, and one which will grow in any ordinary garden soil without attention.

Meconopsis Wallichii.—This handsome Himalayan Poppy is now in full beauty in Mr. Ware's nursery at Tottenham. It is between 4 ft. and 5 ft. high, and forms an erect pyramid, the upper half of which is covered with pretty pale blue blossoms, which droop gracefully from the slender branchlets. It is also one of the most conspicuous plants in flower on the rockery at Kew, where it has withstood the severe cold of the past winter without the least injury.

Musa Ensete at Kensington Palace.—*Musa Ensete* planted out is producing a very fine effect at Kensington Palace. It would have been better, perhaps, had the plants not been placed at equal distances apart but thrown into two or three bold groups. The bedding out here seems to be of a very common-place order, consisting wholly of Pelargoniums rather overcrowded. The fine-foliaged plants are, however, well worth seeing, and will probably improve if we have a continuance of warm weather.

Masdevallia velifera.—This rare and singular Orchid is now flowering in Mr. Bull's nursery. Its leaves are about 6 in. long, erect, and of leathery texture. The flowers are borne on short, stout stalks, and are 6 in. across, in three alternated segments. The colour is olive-green, shaded with a deep bronzy tint, and the whole shining as if it were varnished. It is a native of Colombia, and is well worth including in collections with other curious species.

The Dangstein Sale.—The last portion of this fine collection was disposed of at Stevens's the other day. Some of the rarer kinds of Orchids realised good prices; amongst these, the true Cattleya *labiata* fetched from £10 to £30; *Dendrochilum filiforme*, £15; *Masdevallia tovarensis*, £13; *Sobralia maerantha* from £11 to £13; *Masdevallia Estrate* from £8 10s. to £9 10s.; *M. Veitchiana*, £8 10s.; *Cattleya gigas*, £8; *Dendrobium Griffithianum* from £6 to £16; *Angraecum caudatum*, £15; *A. sesquipedale*, £8; *Masdevallia Chimara*, £5; *M. Harryana*, £4 to £6.

Lilies at Windermere.—The greater number of Lilies from Japan, India, and America which grow in my garden have not suffered from the severe and prolonged frost of last winter. Most of them are stronger than they were last year. *Lilium giganteum* has a stem 6 ft. 8 in. high and 6 in. in circumference at 18 in. from the ground. The spike is 23 in. high and contains fifteen flowers about 6 in. long. In spite of constant storms the beautiful foliage is almost uninjured.—F. CLOWES.

PLATE CXCI.

A GROUP OF CYCLAMENS.

Drawn by CONSTANCE PIERREPONT.

RATHER more than thirty years ago a writer in one of the gardening periodicals published about that time, remarked that "although the *Cyclamen persicum* has been upwards of a century in our possession, we do not seem to have made that progress in its cultivation which its merits would give us reason to expect." At that time the method of cultivation was not of a character to bring forth the highest qualities which this beautiful flower possesses, though there were not wanting those who were beginning to comprehend that the system of culture then followed was open to serious objection; and one noted grower of those days remarked, "that he held decided opinions against the summer drying or roasting of the *Cyclamen* then adopted." Many fine bulbs were lost by so doing; neither did they throw up so many nor such fine blooms as those that have not been forced to rest against their will as soon as they have done flowering. Nor can we wonder that such should be the case, seeing that the foliage is destroyed before it has laid up in the bulb a sufficient store of nutrition to sustain it through its forthcoming trial. In all probability this writer lived long enough to see his opinions put into practice; the roasting process in relation to the *Cyclamen* is now a thing of the past.

The coloured illustration of *Cyclamens* given in this week's number represents some of the finest and newest varieties, belonging to the *persicum* type, raised by Mr. H. Little, of Hillingdon, and Mr. H. B. Smith, of Ealing Dean. These two raisers have of late years obtained some most beautiful forms, large in size, stout in texture, and of varying colours—some very rich and deep; others exquisitely delicate, but all distinguished by high class quality. With finer flowers has also gone on simultaneously an improvement in habit, while the improved strains flower with especial freedom. What is known as the large-flowered type has increased with remarkable rapidity; the flowers are much larger than those of the ordinary *C. persicum*, and yet as freely produced, and the habit of growth as elegant. This large type generally produces flowers of soft hues, but there are indications that a much greater depth of colour is being secured. Messrs. E. G. Henderson & Son deserve honourable mention for the part which they took both in improving and popularising the *Cyclamen* thirty years ago. The work so laudably begun was taken up by others at successive stages of development, and thus it has been continued until at the present day many are cultivating *Cyclamens* and raising new varieties, and there is no lack of interest taken in such worthy work.

The old plan of propagating the *Cyclamen* by division of the corms or bulbous roots is rarely resorted to now, for the simple reason that a good variety is pretty certain to reproduce itself from seed. Propagation by division was rarely thoroughly successful. Names are now seldom given to particular varieties, and even when some fine kind is awarded a first-class certificate no attempt is made to increase the particular plant so distinguished. Its great value lies in becoming a pollen or seed bearing plant. Those who lay themselves out to obtain improved varieties, and especially those who breed for improved hues of colour, go systematically to work, carefully fertilising the seed-bearing flowers as early in March as possible, according to the weather—though it may be done as late as April. The earlier it is performed before that the less danger is there of the fertiliser's delicate work being neutralised by insects and other agents. Cross-fertilisation should be carried out when the sun shines brightly, and when accomplished the plants should be placed in a shady part of the greenhouse, but still having as much light as possible. No place, indeed, can better suit them than a shelf protected from the hot sun by wood-work, about 12 in. or 18 in. from the glass. The seed ripens at the end of July or early in August, and it is the usual practice to sow it as soon as it is ripe. It should be sown in shallow pans or in pots in a light, rich, sandy soil, and these should be placed in a house or frame where there is some bottom-heat, in a temperature of 65° or thereabouts. By the end of November the seedling plants will be large enough to be pricked off into 3-in. pots, placing a dozen or so of the plants in a pot, and still keeping them in a warm, moist atmosphere. During winter these

young seedling plants, whether remaining in the seed-pans or potted off, require to be kept in a warm house and near the glass where the temperature will not fall below 45°. It is necessary to screen the young seedling plants from the effects of hot sunshine during the months of August, September, and October by means of some shading material. The cultivator does wisely to push on his plants into growth as rapidly as possible, and to do this the more effectually he should pot off singly into small 3-in. pots as many of the plants as he can that are large enough to be so treated. During the dead of winter but little growth is made, but as soon as the days lengthen the plants make speedy progress.

About March or early in April a shift into a larger pot should be given, and those plants that remain in the store pots should be potted off singly as already recommended, and all should be put in a frame having a little bottom heat till the end of May, when they may be removed to a cold frame facing the south-east, be kept close for a few days till inured to their new quarters, and finally fully exposed by day. It is important at this point that the plants be not too much crowded. The *Cyclamen* is spoilt in appearance when the specimens are drawn, and by overcroding they become so. The more space there is, reasonably speaking, the better developed and more symmetrical will the plants become. A model plant should have the leaves 4 in. to 6 in. in height at blooming time, with the flowers rising well and evenly above them. During the hot weather that usually prevails in July, August, and September, a sprinkling overhead should be given once in the forenoon, in addition to plentiful waterings at the roots according to the weather; the sprinkling should be done with a watering-pot having a fine rose, as an undue force or weight of water would cause the foliage to hang down and spoil its symmetry of arrangement. The cultivator should especially guard against putting the lights on the frame at night till the leaves are quite dry, or they become much drawn. The most forward of the plants thus treated will come into flower in October and November, and the later ones will furnish blooms till May. In this way the *Cyclamen* can be had in flower successively for the space of seven or eight months.

Cyclamens will bloom for several years if properly treated, and some of the finest plants shown by Mr. Little, Mr. H. B. Smith, and others, have averaged from three to six and seven years of age. As soon as they have done flowering they should be kept in a shaded cool house or in a frame, kept as cool as possible, but on no account should they be allowed to suffer from drought. They pass through a season of rest, but that is a very different thing from roasting the plants well nigh to death in the sun. According to the time of flowering should the plants be re-potted. Those that bloom in the autumn should be re-potted in July; those in the spring, later. When re-potted, they should be placed in a cold frame and kept close for a few weeks. In a short time they push into growth, and soon begin to show their flower-buds, when they require to be grown on generously in a cool house, but on no account actually forced. It was once the custom to leave the bulbs in the pots for two or three years together without re-potting them; the only thing done was to remove some of the surface-soil in spring, and top-dress much in the same way as is done with *Auriculas*. Now cultivators agree in the necessity for and advantage of re-potting annually. In potting, the bulbs should be pretty entirely exposed; the reason being that roots are put forth from the surface of the bulbs, and not from the base thereof, as was formerly imagined. The soil usually employed for *Cyclamens* in all stages is one consisting of two-thirds of coarse leaf-mould, the same quantity of light loam, one-fifth old cow manure (quite clear of insects), and sufficient white sand to keep it open. This makes just the light, rich soil which *Cyclamens* like, and in which they flourish when properly managed. Particularly do they appear to appreciate leaf-soil, and when the seed is sown it should be in the compost.

Many have failed with *Cyclamens* through unskilful management. Those who grow them in quantity should have a house wholly devoted to them, in order that a uniform treatment can be adopted. They are too often either roasted or starved. They like a genial temperature, with quickening warmth in autumn, winter, and spring. *Cyclamens* are unrivalled as winter and spring flowering plants, and they are most serviceable, owing to the long time the flowers remain fresh, both on the plants and in a cut state. R. D.

Foxgloves at Kew.—Few plants, even at Kew, have been more admired of late than the stately Foxgloves, which spring up here and there in large masses amidst the low-growing shrubs with which they are associated. The rich colour of their blossoms, which varies from pure white to a deep purple, all being copiously spotted, has a charming appearance. Such plants as these, which perpetuate themselves freely from seed without the slightest care, ought to receive more encouragement, especially at Kew, where there is ample space for their full development.

A GROUP OF CYCLAMENS

GARDENING FOR THE WEEK.

Flower Garden.

The improved state of the weather has had a marvellous effect on all kinds of bedding plants, which at one time looked wretched in the extreme; they are now, however, brightening up. Such a cold wet season must necessarily induce us to reconsider this system of decoration, with the view of making greater use of hardy plants for summer bedding, seeing how short-lived are all such plants as Coleuses, Iresines, Alternantheras, &c. The maintenance of neatness will now be the main requirement—neatness not only of walks, shrubberies, and lawns, but also of every individual bed by picking off unsightly flowers, leaves, and seed-vessels, pegging, tying, and the like, according to circumstances and the form or design of each bed. Of course, allusion is here made to geometrical planting, to which, however much some may object, so long as it is geometrical, attention must be paid to keeping the form true as when first marked out on the soil. Even in mixed, or what may be termed promiscuous bedding, a certain amount of "dressiness" is necessary in order to obtain the best effect, such as not allowing tall growers to overrun the dwarfier plants, or the edgings and divisional lines to present a broken outline. This is a good time to fill up any spare space there may still be in mixed flower borders with seedling Wall-flowers, Antirrhinums, Pentstemons, and Sweet Williams. We generally plant them out in clumps of three or five plants together, and give them a good watering when they are first put out. All the attention required afterwards is protection from slugs until they have become well established. Herbaceous plants generally this season need more than the usual amount of attention as to ties and supports, and certainly as regards weeding, for hoeing has been impossible, owing to the constantly saturated state of the soil. Dahlias, Hollyhocks, and all large-growing sub-tropical plants should be frequently looked over, and be kept tied to stakes as growth progresses. Roses should have all decayed flowers cut off at least twice a week, an operation which will tend to the earlier production of a second bloom. Stir the ground about them deeply and if they lack vigour of growth, give a good dressing of guano; its effects will soon be visible in the darker hue of the foliage.—W. W.

Auriculas.—The remarks of Mr. Daniel Witter, of Denver, Colorado (p. 80), suggest a few observations on the insect pests and diseases of the Auricula. Many collections in Great Britain and Ireland have been attacked by mealy bug. It has not appeared in our collection at Loxford, but several collections with which I am acquainted are infested with it. One grower states that it nearly decimated his collection in 1877, but I hear from other growers that it does not injure the plants very much. My opinion, however, is that if it lives, as it undoubtedly does, upon the juices of the plants, it must in time injure them. The best way to get rid of it is to turn the plants out of their pots, and wash all the soil from their roots, then wash the roots and collar of the plants with soapy water, scrubbing out the interstices with a brush, laying the plants down, and in an hour washing the roots again with clear rain water; then repot in the usual way with clean soil. At this season a maggot, very similar to that which attacks the young growths of the Rose, eats its way into the crown of the plants, causing much damage. It can be destroyed only by watching for it, and killing it with the fingers. A smaller green maggot eats the under sides of the leaves, and must be killed in the same way. Green fly is a very troublesome pest, and must be destroyed as previously recommended.

Carnations and Picotees.—These ought to have daily attention. It will be difficult to get Carnation and Picotee fanciers to abandon the use of cards for their flowers. Some varieties, indeed, must have cards placed to them before the outer petals open: Daniel's Dreadnought and Eason's Admiral Curzon are flowers of this type. The cards prevent the petals from reflexing too much, and the colours are certainly shown up better on cards than without them. Every day it is necessary, too, to look to the flowers the calyxes of which have a tendency to split, and to open them out on the opposite side, tying them round with a strip of bast. Green fly will cling to the youngest buds, and it also attacks the young growths under glass; it ought, therefore, to be brushed off.

Dahlias.—If a Rose show can be held in August, when will it be best to fix the date of Dahlia exhibitions? A postponement until next year looks as if it would be the best arrangement. The plants seem healthy enough, but they are very late. The watering-pot has not, however, been required: under such conditions it is well to place some rich dressing over the roots. Guano speedily shows its effects; it is best to sprinkle the whole surface of the beds with it, and then work the ground over with the Dutch hoe. Fowls' manure used in a dry powdered state is also an excellent fertiliser, and over these dressings some rotten frame manure may be placed.

Gladioli.—I have written on previous occasions concerning the degeneration of the varieties of *G. gandavensis* in this country. I cannot think that it can be attributed to any other cause than the humidity and low temperature of our insular climate. The cold nights and autumn rains come upon the plants long before the bulbs are ripe and check their development. One good grower attributes the degeneration in question to the bulbs being too long out of the ground. There may be something in that, but it is certain that our climate is too wet and cold to ripen them perfectly. It would be well for some one to try and improve the early-flowering species, some of which are very fine indeed. Amongst a few of them exhibited by Mr. Elwes at South Kensington on July 22nd, one, a well-shaped flower with bright red petals marked with white, was singularly beautiful. Its name unfortunately was unknown.

Phloxes.—These are now showing flower; at least, such of them as have been grown in pots, and they will be useful for furnishing the greenhouse when the Pelargoniums are removed. The early-flowering section has done well this year, showing that a cool moist season suits them best. Under ordinary circumstances a grower near London would condemn the early-flowering Phloxes. One cultivator considers them delicate, but this is not the case, as they do exceedingly well in Scotland. They do not, however, withstand drought and heat, while the late-flowering section does not object to heat, provided they are well supplied with water at the roots.

Delphiniums.—If it is not intended to save seeds of these the seed-pods should be removed in a green state; this will cause the side stems to flower stronger.

Pentstemons and Antirrhinums.—These useful hardy plants are now coming into bloom, a condition in which they will continue until frost sets in. Tie the stems to sticks as they advance in growth, and as they do not require water at the roots this year, it will only be necessary to keep the beds in which they are planted cleared of weeds.—J. DOUGLAS.

Conservatory.

Indoor Aquatic Plants.—Aquatic plants are not nearly so much grown under glass as they deserve to be, and where they are cultivated they generally consist of stove species that require a high temperature; doubtless these are very beautiful, but the disadvantages attending them are that the more important kinds attain a large size, requiring a corresponding amount of space, and the sweltering heat in which they are grown makes the atmosphere anything but enjoyable during warm weather. No conservatory need be without a suitable place for growing such aquatic plants as will thrive in a usual greenhouse temperature. It may be formed by ordinary stone or slate slabs put together in the usual method, or it may be a wooden trough lined with lead, the outside of which, if desirable, can be covered with cork or other material to give it a rustic appearance. Its dimensions will require to be in keeping with the size of the house; a depth of 2 ft. will be sufficient, and I should advise the plants in a great measure being confined to pots, as the stronger-growing species will this way be under more control, and their arrangement can be altered at will, so as to avoid the, to many, objectionable feature of plants always occupying the same positions. Such a receptacle as that just described should be supplied with water by means of a pipe and tap that will give a slow trickle for some hours almost daily, with a corresponding outlet by an ordinary overflow, with means to convey the water away. In this matter there will be little difficulty if there happens to be a tank beneath the floor for holding the roof water. One of the most suitable plants for growing in conservatories is the Cape Hope *Aponogeton distachyon*; its singular highly fragrant, Hawthorn-scented flowers emit the most agreeable perfume, and they continue in bloom through a great portion of the spring and summer. It should be grown in pots in loam and placed a few inches below the surface of the water, setting the pots which the plants occupy upon others inverted. A few examples of the Grass-like leaved *Vallisneria spiralis* may also be grown; its leaves when placed under the microscope show the circulation of the sap so well as to make them objects of interest. It will succeed in 6 in. or 8 in. pots, with a few crocks in the bottom, and filled with loam. The pots containing it may stand on the bottom of the tank. *Trapa natans* (the Water Chestnut) is another subject deserving of notice. It will grow in soil similar to that recommended for the *Vallisneria*, but it requires a larger pot. The North American white *Nymphaea odorata* will need a moderate-sized pot, and, associated with it, may also be the Chinese *N. pygmaea*, a white-flowered kind which will likewise succeed in loam and similarly treated. *Dietsa bicolor* is another plant that does well managed in this way. It should be potted in loam, and is distinct in habit. The North American *Orontium aquaticum* will be a good addition, as would also be the Chinese *Sagittaria sinensis*; loam, with a little sand, will answer for this.

To these may be added the green and variegated leaved Callas, which succeed well in loam, and may stand with their pots from 12 in. to 6 in. beneath the water, according as their heads will look best. These Callas should not be allowed to get too large; they may be divided yearly if necessary, and, if thought desirable, can be grown as ordinary greenhouse plants, and be introduced to the water when coming into flower and removed afterwards to make room for others. In this way a considerable succession of bloom may be kept up. There is always a charm attached to plants grown in water this way, but it is essential that the water be kept clean. Dwarf-growing Ferns, such as *Adiantum cuneatum*, *A. gracillimum*, and the taller *A. formosum*, together with the many crested forms of *Pteris serrulata*, *P. cretica albo-lineata*, and also the green *P. cretica*—the latter one of the best of all Ferns for bearing hard usage—may with advantage be interspersed amongst the dwarf-growing subjects grouped in this structure. All plants introduced to conservatories from warmer quarters must be carefully treated as regards water, which should only be applied at a temperature approaching that to which the plants have been accustomed; but they should receive no more than is necessary to prevent the soil from getting so dry as to cause them to flag.

Achimenes and Gloxinias.—Some of the latest-started that have received as cool treatment through the summer as they could be induced to make progress under, will, when beginning to flower, be in the best condition for standing in the conservatory, being careful not to admit the cool external air directly in contact with them. Where plants are arranged in groups on the floor, or on low table-like stages, it is always well to avoid the pots being more seen than is necessary; and, in order to effect this, sufficient numbers of *Isolepis gracilis* and *Lycopodium denticulatum* should be grown in 4 in. or 5 in. pots so as to stand as close as the pots will admit in the immediate front of the arranged groups. A good effect may be produced by introducing amongst these green plants *Coprosma Baueriana variegata* and small examples of the white-leaved *Centaureas*, together with anything else at hand that will take off the stiff formality of continuous rows of one or more kinds.

Greenhouse.

Plumbago capensis.—Few plants are so useful as this at this season of the year, grown in small pots, either for large conservatories, small greenhouses, or anywhere where blooming subjects are required. Plants that have already been in flower for some time will generally push up side shoots from the stronger branches, which make excellent cuttings, if taken off now and treated in the ordinary way: they will get established before winter, and will make serviceable flowering stock for next summer. A sufficient number should be prepared, as they are of much more use in a small than in a large state, and the delicate blue shade of the flowers furnishes a colour which we need, and which harmonises well with everything else it is associated with.

Fuchsias.—These, so generally useful for almost every purpose, and so easily grown, are, nevertheless, with few exceptions, worse managed than the majority of other plants. The fault ordinarily lies in retaining scraggy samples devoid of lower branches, and which, despite whatever flowers they may bear, are far from having so good an appearance as young, well-furnished plants with branches hanging gracefully down so as to almost hide the pots. They strike, too, like weeds, and the present is the best time in the year for putting in cuttings in order to get young stock that will bloom as early in the spring as is required in a comparatively small state; or they may be grown on at the option of the cultivator to as large a size as may be considered requisite for later flowering. Shoots that have formed bloom root indifferently, and never make good plants. Young growths should be chosen from near the base of the stronger branches. Put these say half a dozen together in 5 in. or 6 in. pots, drained and filled with sandy soil, covering with a bell-glass. Keep them moist and shaded in a little warmth. Take care that the cuttings previous to insertion are free from aphides and red spider, especially the latter, to which Fuchsias are subject at this time of the year. Out of the many fine varieties that now exist there need be no lack of choice; but there is a great difference in their inclination to flower early. Amongst all that have been raised, none find so much favour with market growers as regards their early free-blooming disposition as the white rose-corolla'd variety called Mrs. Marshall (syn. *Arabella*) and the crimson kind, with violet corolla, named *Try Me O*. The plants which bloomed early, and which are now getting shabby, should be turned out of doors for a fortnight, and should receive no more water than will keep them from flagging too much; then let their side branches be well shortened in and the main stem slightly reduced, giving a good washing with Tobacco water, to which a little Gishurst has been added so as to free them from aphides, thrips, and their eggs, and then put them in a pit that can be kept close and slightly shaded. Thus treated, and

syringed overhead daily, they will quickly break into fresh growth. If in comparatively little pots, they may have a small shift; but if they have sufficient room already, weak manure water will answer. Under this treatment they will again get well furnished with branches that will keep on flowering until the end of October or later, and they will be found very serviceable for greenhouse and conservatory decoration, as well as for cutting, in which condition their flowers will last much longer than earlier in the season.

Petunias.—The beautiful single forms of these raised from seed sown early in spring furnish useful decorative flowering plants through the summer for conservatories and greenhouses; but their natural straggling habit is a defect that does not exist in the double-flowered kinds. The latter keep on blooming for months without getting at all denuded of their leaves or unsightly. These are increased by means of cuttings, which, for flowering next year, should be put in now, selecting for the purpose the young soft shoots that will generally be found springing from near the base of the plants now in bloom. Treated in the usual way they will root in a few weeks, when they should be moved singly into 3 in. pots into sandy loam, and placed through the autumn and winter on a shelf near the glass, where they will keep on making slow progress, and be in a proper state for moving on early in the spring. Petunias both double and single that have been blooming for some time will be much benefited by the use of manure water.

Vallota purpurea.—This beautiful plant is one of the most useful which we have through this and the succeeding month, as where a sufficient stock of it exists there is no difficulty in having it to come in in succession during that time. It is most serviceable when grown in from 6-in. to 9-in. pots, with from a couple to half-a-dozen bulbs in each, as it does not like too much root-room. After the flower stalk first shows itself the blooms come on very rapidly, and where a succession is needed a portion of the plants may be retarded by placing them in a frame at the north side of a wall, where they will be little under the influence of the sun. The *Vallota* is a plant that requires to be kept always moderately moist, especially when exposed to sunshine; but whilst in chilly quarters it must not be kept overmoist. Attend to advancing stock of this plant taken off in the spring from the larger bulbs; give all the light that a good well-glazed house affords and plenty of water, by which means the bulbs will increase to a blooming size much quicker than if subjected to comparative neglect.

Late Heliotropes.—Plants of these propagated in spring will now be found useful for blooming late in the autumn when flowers are scarce. They are always acceptable both on account of their colour and perfume. To have them in a condition to bloom freely they must be well attended to; when their pots are full of roots manure water will much assist them. The old variety is still a general favourite, but under glass rather light coloured. *Etoile de Marseille* is a fine kind as regards colour, as is also *Madame Fillon*. Standard and other large plants that have bloomed for a considerable time under glass should be supplied weekly with manure water sufficiently diluted, as by no other means can plants that continue through the season producing a succession of growth and flowers be kept in the vigorous condition which is essential not only to their healthy appearance but to enable them to bear the full amount of bloom of which they are capable.

Chrysanthemums.—The time is now come when Chrysanthemums want the most careful attention, without which, no matter how well they have been treated in the early stages of their growth, or what may be subsequently done for them when nearer blooming, they will fail to give satisfaction, for, now as their pots are getting full of roots, should there be any neglect in not keeping the soil sufficiently moist, or in supplying them with liquid manure regularly, they will neither retain their foliage in a fresh healthy state down to the base, nor will they produce such a head of fully developed flowers as they otherwise would do. Where the plants are plunged see that the roots do not grow through the bottoms of the pots. Keep the branches regularly tied so as to avoid breakage through wind, and place them sufficiently far apart in a light position to prevent them becoming drawn, and to admit of getting amongst them to water and syringe them, which latter operation should be practised in the evening of every dry day.

Pelargoniums.—The earliest-flowered large varieties of these that were turned into the open air recently should, now that the lower part of their shoots will have assumed a hard brown colour indicative of the necessary ripened condition, be cut down, leaving two or three eyes (according to the size of the specimens) above where the shoots spring from, and as soon as the heads are thus removed place the plants in a pit or frame, where they will be protected from too much wet; keep them a little close and syringe them overhead daily. Thus managed they will push young growths forthwith. The fancy varieties may be treated in a similar manner, but

they do not require (nor will they well bear) cutting in nearly so close as the large-flowered kinds, and in their case it is even more necessary to be careful that the roots do not get too wet.

T. BAINES.

Hardy Fruit.

The gales of wind and rain which occurred on the 19th and 20th ult. made a final clearance of all fruits likely to fall off ere they were fully grown, and so did not prove an unmitigated evil: certainly all that weathered such storms may be expected to attain full growth, and therefore no further injunctions as to thinning out the fruit are necessary. The excessively wet condition of the ground is causing Cherries to burst before they are sufficiently ripe, and doubtless this will be the case with other kinds of fruits as they approach maturity. It will be advisable, therefore, not to attempt to keep them, but gather them as soon as they are ripe enough for preserving. Strawberries have proved better than, under the circumstances, could have been expected, for though a large percentage rotted, the crop was so large that a portion could well be spared. The plants should now be cleared of runners and the ground "pointed" over. New plantations may also be made, either with forced plants or newly-formed runners. Deeply and well enriched ground is indispensable to the production of fine Strawberries. The season has suited Raspberries, which are wonderfully fine, and the plants are making extraordinary growths; it will therefore be absolutely necessary to thin out the new canes to the minimum point—about three to each stool—and, as soon as the fruit has all been gathered, any of the old canes that interfere with the full development of the new growths should be removed. In order to prevent injury from wind, the new canes should also be tied in at once. The new shoots and points of cordon and espalier-trained trees of Apples and Pears may likewise now be tied in. Spur back all growths not required for furnishing the trees to within three joints of the old wood, an operation which, combined with partial root-pruning at the proper season, will conduce to fruitfulness. The majority of Peaches and Apricots may now have the current year's shoots laid or tied in to the wall, but previously pinch closely back all sub-lateral growths that have formed on them. Any trees that have suffered from the effects of last winter's severity, and which have not yet fully recovered their former vigour, may still be left to grow unrestrictedly, but no fruit must be expected from them next season. Keep down aphides and red spider by occasional syringings with soap-suds or a weak solution of Gishurst Compound.—W. W.

Parks and Open Spaces.

No pains should be spared in maintaining shrubberies and herbaceous borders free from weeds, which the wet weather which we have lately experienced has rendered a continuous work, nothing short of digging in or hoeing up and raking off having availed to keep them in anything like good order. It will be advisable, now that trees and shrubs are at their best as regards foliage, to mark those which can with advantage be removed during the winter. A much better idea of the natural arrangement of foliage can be arrived at by this means than if left until the deciduous kinds have lost their leaves. The same remarks as regards observation apply to those who may contemplate planting, either in groups or singly, weeping and other trees round the margins of lakes. Many excellent herbaceous plants are now blooming profusely, and care should be taken that their flower-stems are secured where necessary to light stakes; where this is neglected the beauty of the display is often lost, owing to their being broken in consequence of the weight of their flowers, or to their lying close to the ground, as in the case of Carnations and Picotees, especially in wet seasons. All decayed flower-stems should at the same time be removed, and the seed-heads of such plants as *Heracleum* should be cut off and destroyed, as from their prolific nature they will cause some inconvenience.

Cricket and croquet grounds which have been properly made, especially as regards drainage, should be available for the purpose for which they were formed at all times during the season, except after heavy rains, in which case a few hours should be allowed for the surface-water to soak down. The Grass should be frequently mown, for, if neglected, long Grass has a great tendency to destroy the turf. It is well to have a quantity of turf available and to constantly replace that on spots in which it is sure to be destroyed. It is a mistake to suppose that cricket or croquet grounds can be made too dry; drains are extremely beneficial in wet seasons, and with due care they are not detrimental in dry ones. The secret of maintaining a durable and suitable turf lies in dressing, watering, mowing, and rolling as often as may be necessary; a few inches of good soil—that of a fibrous texture being the toughest and best—upon a gravelly or otherwise well-drained base, will form the best surface. When much used in the course of the season, such grounds should, if possible, be given a rest during the whole of the winter months.—C. DENNIS.

Extracts from my Diary—August 4 to 9.

FLOWERS.—Nailing in young shoots of Camellias on back wall of Peach-house. Potting Poinsettia and Begonia seedlings. Thinning out Primulas, in order to give them more light and air. Putting in cuttings of Fuchsias for winter blooming. Sowing herbaceous Calceolarias. Re-arranging plant-houses. Putting in cuttings of Roses of the current year's growth under hand-lights on the north side of a wall. Propagating bedding plants for next year, beginning with fancy Pelargoniums. Shifting small Chrysanthemums growing for late use out of 3-in. into 5-in. pots.

FRUIT.—Gathering all Apricots and Plums that are ripe. Planting last plants of Netted Victory of Bath Melon in pots and setting them in Pine stove in place of pot Vines, shifted from there, where they have been grown, to a lighter house to ensure ripening. Potting Strawberries for fruiting next year. Trenching ground for Strawberries for the next plantation.

VEGETABLES.—Digging up all early varieties of Potatoes. Planting large quarter with Cabbage; also Brown Cos Lettuce. Clearing up Potato haulm; also rubbish off Strawberry beds, and preparing for crops of Winter Greens. Planting out Little Pixie Cabbage and Rosette Coleworts. Tying and stopping Cucumbers. Sowing more Little Pixie Cabbages on south border. Nailing and stopping Tomatoes on walls outside. Sowing Mustard and Cress. Thinning out superfluous wood of Cucumbers. Cutting all herbs wanted for drying for winter use, and storing them in fruit room. Shelling Peas placed in fruit-room to dry for early use next year. Planting out Tom Thumb Lettuce between Celery trenches. Planting out last batch of Major Clarke's Celery. Gathering seeds of Burghley Broccoli to dry. Gathering Scarlet Runners that are ready.—R. GILBERT, *Burghley*.

NOTES FROM CALIFORNIA.

The Beurré Coit Pear.—This is a native American Pear which has gained a good character. It was originated by Col. Coit, of Ohio. The report of the department of agriculture says "It is of such excellence as to deserve a place in all collections," and Downing gives it a good name. The tree is a hardy, vigorous, and upright grower, becoming spreading as it matures; it has dark brown shoots and broad waved leaves, with rounded serratures, and is productive, and comes early into bearing on the Pear roots.

A Large Oleander.—Mr. Griffith, of Yolo County, lately showed us the largest Oleander it has been our fortune to find hitherto. The trunk is about 11 in. in diameter at the surface of the ground, and fully 8 in. in diameter at the parting of the branches, which is 2 ft. above the ground. The head is wonderfully large and symmetrical, and is supported by bars nailed in the form of a square, and lifted up on posts set near it. Being in full bloom when we visited it, the effect was that of a superb bouquet of Brobdignagian proportions.

The Double Red Pomegranate.—We lately saw some large specimens of this remarkably handsome shrub. The double kind is better than the single, for the flower is larger and lasts much longer. The Pomegranate is a sort of classic shrub. Planted upon the hillsides of Pleasant Valley, with the sleepy blue of the mountain ranges beyond, it gives the place an air of Asia Minor. It has the glossiest of leaves, and the most graceful of drooping branches. Sometimes a bush looks like a fountain perpetually flowing, and, at this season, lit with flashes of scarlet fire. Then, also, the leaves grow golden-yellow in autumn, and add another, though evanescent attraction. Now, let whoever has a spare corner plant a double Pomegranate next winter.

Cacti on Rocks.—One day, not long ago, as we rode slowly up a winding mountain road, we passed a cottage surrounded by Vineyards which covered a rounded hill near the house, and crept far up the mountain slopes until the soil became scanty, and rocks thereafter possessed the ridges. Pink wild Roses covered the rude fence of slowly decaying logs, and close beside the cottage was a rugged pile of weather-beaten rocks, in whose crevices Vines clung and tangled, while, on its sunnier side, a dozen brilliant scarlet-blossomed Cacti had been planted. That one flash of Cactus colour, which, as our readers know, is indescribably velvety and glorious, was the central point in the landscape, and yet found a sufficient relief in the rays of soft green on the summer hillsides, and in the deep masses of entangled Vines about the base of the rocks, which even half hid the scarlet flashes. Is there no suggestion here for our own wild gardens? Let us try something similar if there is any rocky point, or southern slope, intensely hot during summer.

The Growth of Horticulture.—As we, this summer, have been travelling through the central and northern counties, there has

been a distinct and very gratifying impression of improvement, on the whole, in country gardens. More flower gardens there are now, most certainly, than there were two or three years ago. People are beginning to improve their places. We are not any longer a State of campers; we are home-builders; we mean to stay here and eat the fruit of our own orchards, and pick the Roses of our own gardens. This is, certainly, a very hopeful state of affairs, which to encourage is our duty and delight. No depression in business or excitement in politics can alter the currents so strongly setting in towards horticultural pursuits.

Piedmont School Gardens.—Last month we advocated the planting of flowers in school-yards, and a most gratifying instance of ornamenting school-grounds has recently been brought to our notice. At Piedmont, in Alameda County, the grounds belonging to the school have been laid out in symmetrical beds, and planted with trees, shrubs, and soft-wooded plants. So far everything flourishes, and children help to take care of the flowers, and prospects are bright indeed. Mr. H. P. Livermore, one of the trustees, sent five two-horse loads of plants as a gift, and had them planted at his own expense.

Tomatoes from Cuttings.—We were shown a beautiful and thrifty Tomato plant in a garden recently, and were desired to "look at it hard," but, failing to discover ought else than Tomato leaves and blossoms, came back upon our querist with a Yankee-like reply of "What is it anyhow?" Well, it was grown easily and rapidly from a cutting of new wood, and, we are told, this is done to a considerable extent in the southern counties. We are not aware that any one, even in warm localities, has tried this plan for market plants. It might be cheaper than seeds, but we should hardly think so. If, however, a chance seedling should show marked advantages, this method would ensure its perpetuity.

Mr. Blowers' Vineyard.—At Woodland, in Yolo County, is one of the most successful Vineyards of our State. Mr. R. B. Blowers became interested in the problem of Raisin-making some years ago, and was the first to produce a good marketable raisin on this coast. The Grape used for Raisins is the Muscatel, which is preferred to the Muscat of Alexandria, probably the next best variety. Mr. Blowers' vineyard is situated on a fine level tract of land near the town. An irrigation ditch takes water from the Creek, whenever it is thought desirable. This is only used for flooding the Vines in winter in order to prevent the Phylloxera from establishing itself. No irrigation is needed for any other purpose, the Vines making a luxuriant growth, and bearing heavily without it. They average, acre after acre, forty pounds to the Vine. The Grapes are allowed to get fully ripe, and are then gathered and placed on trays made of boards, about 3 ft. by 2 ft. square. One of these is set by each Vine, and is tilted towards the south by a clod of earth placed under it. If the season is favourable, the first crop of Grapes can be dried in this way. If not, the trays and their contents are taken to the drying house, where the second crop, at least, is mainly dried. This drying house, Mr. Blowers' patent, is a compact, effective, and economical affair. It is better adapted to Raisins than any other style we have seen, on account of the dry heat used, its evenness, and its perfect control. In this Vineyard we also saw several acres of the Emperor Grape, probably one of the best for shipment to a distance. This Grape is a shy bearer, but, by close pruning and tying the new growth up each year, it has done better than usual here. The leading foreign varieties are represented, but not in large numbers. This is a "Raisin farm."

The Oak Shade Orchards.—Our friend, Mr. J. B. Saul, nurseryman and seed-grower in the earlier days of California, is one of the owners of the Oak Shade Orchards near Davisville. Three hundred and twenty acres here are almost entirely devoted to fruit trees and Vines. The avenue up which one rides, is of California black Walnut, a beautiful tree, and of more rapid growth, in the warmer parts of our State at least, than is the Eastern species. There are 12,000 Pear trees, most of them beginning to yield well. The four leading varieties are Bartlett, Winter Nelis, Doyenné D'Alençon, and Beurré Clairgeau; Easter Beurré and Glou Moreceau are grown in lesser quantities. These Pears are shipped eastward, and were planted for that purpose. The trees are mostly young, and not in full bearing condition. Portions of them are budded on seedling stock, planted in permanent form some years ago, and this, it is thought, will make more lasting trees. A large portion of the orchard is devoted to almonds of the Languedoc variety. We may remark that we have particularly observed the condition and prospects of the almond wherever found, and, in many localities, must pronounce it a failure, so far as bearing properties are concerned. But there are many other places where the Almond promises to succeed well; in Pleasant Valley, at Mr. Thurber's, the prospects are encouraging; the same is true near Woodland, and also here at Davisville. The Almond, when it does succeed, pays so well that it is worth while

for any man to test it if he has any sheltered nook free from chilly winds and late frosts. The Vineyard covers fifty acres, and most of the produce is made into Raisins.

Bearing Pecan Trees.—On Mr. Briggs' large fruit farm, half a mile south of Davisville, we saw some forty thrifty and well-grown Pecan trees in bearing. They are eleven years old, and are considerably larger than English Walnuts of the same age, which stand near them. They were heavily loaded with tassels of bloom, but the nuts, which form in hanging clusters on the tips of the young wood, had not yet appeared. The Pecan, Mr. Briggs thinks, might be made a profitable tree, although the Almond, where it succeeds, is better. A handful of last season's growth, taken from the sack without selecting, was finer in flavour and larger than any imported which we have ever seen. The Pecan is a handsome and fruitful tree. Small trees must be chosen to plant, as large ones are hard to move safely.

A Fig Orchard.—In Yolo County, not far from the snug little town of Winters, there is a Fig orchard of some twelve acres in extent. The location is level, soil a good loam, 15 ft. above the water. The variety mainly used is the black California Fig, which has dried most easily. Indeed, one is surprised to learn how little trouble has heretofore been taken. The Figs have merely been allowed to ripen, fall on the ground, and dry there. They are then picked up, rinsed in warm water, sacked, and sold in bulk. If, in this rude way they pay at all, it is evident, we think, that by careful preparation and packing in small boxes, they would yield a handsome revenue. The temperature in the neighbourhood of this orchard was over 105° Fahr. on the three first days of last June, so that the summers may, without exaggeration, be called warm.

New Early Peaches.—This month there is an abundance of good and cheap Peaches, but none of our readers will have forgotten how high priced are the earliest Peaches whose arrival is with much ardour published by the daily press. Some time in May, earlier or later according to the season, the first Peaches appear from the vicinity of Putah Creek, Pleasant Valley, or Marysville. Briggs' Early May, a well-defined seedling of Californian origin, also the Amsden and the Alexander, both eastern Peaches of good quality and colour, are by this time well known. Another new Peach, as yet but little known, is Hale's Advance, a seedling which originated on Putah Creek. It is quite as early as Briggs' May, and is somewhat larger. If it were not a shy bearer, and liable to sport, in other words, not yet of a fixed type, it would be termed an undoubted acquisition; as it is, it deserves experimenting with. The Waterloo and Brice's, both of which have received mention heretofore, are being tested in this State, and may possibly fruit next season.

A Cherry Orchard.—Early in May we visited the orchards of Messrs. Bassford & Sons, near Vacaville, Solano County. It is a beautifully improved and sheltered place, at the head of a ravine, and is fitly named Cherry Glen. We saw acres of beautiful trees, well grown, well trained, and loaded with ripe fruit. The leading variety grown is the Black Tartarian, for years the standard variety in our markets. Next in popularity come the Royal Ann, or Napoleon Bigarreau, the Elton, and the Mayduke. All these we observed in full perfection. The finest early Cherry is the Purple Guigne, a variety of quite recent introduction into this State. The Cherry trees are trained low, with trunks of not more than 2 ft. in length, and the side buds are allowed to grow, forming a shelter of sprouts around the trunk. The heads present a very uniform appearance, and are kept cut back evenly on the top, so as not to become unmanageably tall.

Protecting Grapes.—Mr. Scarborough, of Cincinnati, has communicated to the secretary of the Ohio Horticultural Society the following method of protecting and maturing Grapes, as used by Mr. Gotlieb, of Cincinnati. Just after the young Grapes were set, he enclosed 2500 bunches in bags made of yellow Manilla paper. The bags were fastened by two or three pins. The cost of the bags, pins, and labour was about one-third of a cent per bag, but on a larger scale would be proportionally less. The advantages claimed are protection from insects, finer flavour, and immunity from rot. Muslin bags may also be used, and would be serviceable for several years.—*California Horticulturist.*

A Happy Old Pear Tree.—At a recent entertainment in a school at Chicago a letter was produced written by Mr. Longfellow, in which he said, in answer to a letter sent to him:—"I can only send you and the boys and girls under your care a friendly salutation. To those who ask how I can write 'so many things that sound as if I were as happy as a boy,' please say that there is in this neighbourhood or neighbouring town a Pear tree planted by Governor Endicott 200 years ago, and that it still bears fruit not to be distinguished

from the young tree in flavour. I suppose the tree makes new wood every year, so that some part of it is always young. Perhaps that is the way with some men when they grow old; I hope it is so with me. I am glad to hear that your boys and girls take so much interest in poetry. That is a good sign, for poetry is the flower and perfume of thought, and a perpetual delight clothing the commonplaces of life 'with golden exhalations of the dawn.' Give all my sympathy and my good wishes."

THE FLOWER GARDEN.

SINGLE AND DOUBLE FRENCH ANEMONES.

THE diversified floral hues which the ordinary *A. coronaria* assumes, combined with its elegantly cut foliage, place it amongst the most popular of border flowers; and the length of time during which the blossoms continue to be produced considerably enhances its value. Those represented in the annexed illustrations are known as French kinds—sorts that are largely grown at Caen and in other places in France, and which are considered to be superior to the Dutch varieties. There are now a host of kinds of Anemone representing almost every shade of colour, from pure white to intense purple and the most brilliant scarlet. They have, too, a striking variation in the duplicity of their blossoms, from the single forms pure and simple to the compact dense rosettes of the best double forms, and the Chrysanthemum-flowered kinds, in which all the stamens are converted into narrow petals, which incurve so as to assume a globular form. The Poppy Anemones, as those here represented are generally called, may be grown in any ordinary garden soil, though they succeed best when planted in a light loam enriched with well-decomposed manure. The border on which they are grown should be thoroughly drained, and the soil before planting should be dug at least 1 ft. in depth. The tubers should be planted either

to protect the borders in which they are planted with Bracken, straw, branches, or similar material. Propagation is effected either by dividing the tubers at the time of planting, or by raising plants from seeds, which in some seasons are produced plentifully. The

Double French Anemones (Vilmorin).

seedlings generally flower the second year, and it is an interesting occupation to watch for those which may possess more merit than the existing varieties. G.

Single French Anemones (Vilmorin).

in October or from February to the end of March; the former date is the best, as the flowers are produced earlier and the plants are more robust. The advantage of spring planting is that a succession of bloom is obtained until June. When the foliage is dead and the tubers thoroughly ripe, they should be taken up, carefully dried, but not in the sun, and stored in a cool airy place till the time of replanting arrives. During severe weather in winter, it will be necessary

THE BREAKING OF TULIPS.

MR. Laxton asks (p. 80) "whether the seedling Florist Tulip, when fertilised solely by its own pollen, will require the usual period to break." There is no such thing as a set or usual period in this unique physiological change that is sure to occur sooner or later in the life of a Florist Tulip bulb. Any offset of a Tulip still in breeder form may break before or after the mother bulb. It may break while yet too young to bloom, showing that fact in advance by the change in its solitary leaf from a solid to a mottled green. If the mother bulb has "broken," say in the current year, the offsets which it has formed this year will be broken also, and be perpetuations of the exact strain of the parent bulb. Those thrown off in the previous year or years will go on in their own independent paths as so many breeder forms of that same sort, till in their own uncertain turns they also "break," and in so doing form so many other strains of the same name as the original bulb that was noted for good, and named once for all, at its maiden bloom any number of years back. It matters nothing, so far as breaking is concerned, whether the flower has been fertilised with its own pollen or not. Presumably, the advantage of a complete cross with another variety in the same class will have been secured by the raiser of thoroughbred seedlings, but he can place no confidence in there being any exciting cause of quicker breaking in this important operation.

I have raised seedlings of the Florist Tulip from time to time within the last twenty-five years, and sometimes both parents were breeders, in other cases one was a breeder and the other a rectified flower, while in other instances both parents were broken flowers either feathered or flamed. In all these cases, as any Tulip raiser knows it would be, the vast majority of seedlings began to flower as "breeders" or selfs. Some, in the course of the years of their bloomless childhood, showed by their mottled Grass that their first bloom

would be a "break;" whilst in instances more rare, a seedling would break just when it first bloomed, and so, like those mentioned immediately before, could be said never to have had a breeder at all.

Perhaps this record of an experience with the Florist Tulip will help to show that Mr. Laxton's second question whether "the seedlings are fixed from the period of their first flowering" cannot be answered in the affirmative except in cases where the maiden bulb has happened to bloom for the first time as a broken flower. There can then be no other strain of that sort possible, all subsequent off-sets being but an increase of that particular strain. Hence it is only such increase as is given off before a break, *i. e.*, while the parent is in the breeder state, that can produce fresh strains, as being so many breeders that have yet to break.

I have been tempted sometimes to cross a Tulip, breeder or broken, with its own pollen, because of the extreme beauty of the parent, and as wishing for more flowers of that stamp, but the effect has not been to make the produce break perceptibly either more or less freely than any complete cross. Distinct as the classes of our Tulip are, yet a pod of seed from any one will give seedlings in them all, together with a large proportion of intermediate flowers, useless to florists, and called tricolors because of the colours of more than one class being mingled in them—*e.g.*, the base of a bizarre with the ground of a hyblemen, breaking into a yellow, violet, and white permanent condition. Old David Jackson once sowed a pod of seed from Aglaia, a venerable scarlet and white flamed and feathered sort that requires a few days to bleach the creamy tint out of its base. Who did not feel for honest, patient David when these seedlings bloomed as a shoal of yellow selfs? FRANCIS D. HORNER.

Kirkby Malzeard, Ripon.

ALPINE PLANTS AT EDINBURGH.

HAVING derived much pleasure from perusing, in THE GARDEN of the 21st ult., the two very interesting accounts of Alpine and rock plants grown in Yorkshire and in Kent, I have thought that a list of some of those which I lately saw thriving and flowering on a rockery in the nursery of Messrs. Dicksons & Co., Pilrig Park, Edinburgh, after the past severe winter and backward spring, might be of interest to readers of THE GARDEN who cultivate these beautiful hardy plants on this side of the Tweed. I may mention that the Messrs. Dickson informed me that they had constructed the rockery on which the plants were growing solely for the purpose of keeping up a supply of stock of Alpine plants for their nursery, and that they had made it by placing large stones at irregular intervals over the surface of several oblong mounds of earth, as many compartments for the plants as possible being left between the stones. Although the soil of the mounds did not appear to me to differ in any respect from that of the ordinary nursery ground, the plants were all growing most luxuriantly, and were in many cases covering the stones with their foliage and flowers.

The following is a list of the plants, the greater part of which were in flower at the time of my visit:

Achillea Clavennæ umbellata	Erigeron atro-purpureum	Polygala Chamaebuxus purpurea
Allium McNabianum	Erius hispanicus	Primula cortusoides (of sorts)
Moly trinetrum	Erodium macrodentum	Manesavi
Andromeda polifolia tetragona	Geranium arvenum	capitata
Antennaria hyperborea tomentosa	cinereum	furiosa
Anthyllis montana	Geum coccineum fl.-pl.	luteola
Aquilegias (various)	Globularia vulgaris	Munroi
Arenaria balearica purpurascens	Gnaphalium leontopodiium	scoticæ, &c.
Armeria maritima alba	Helianthemum vulgare, &c.	Ranunculus speciosus uniflorus
Astragalus hypoglottis albus	Houstonia cœrulea alba	Rhododendron ferrugineum
monspessulanus	Iberis corifolia	hirsutum
Aubrietia Cambellii grandiflora	gibbaltarica	Rosa bracteata
Hendersoni, &c.	superba	pyrenaica
Caltha palustris fl.-pl.	Tenoreana	rugosa
Campanula Allioni garganica	Iris obiensis, &c.	Saponaria ocyroides
butlla	Lilium monadelphum, &c.	Saxifraga cœspitosa
Cardamine latifolia pratensis fl.-pl.	Linum flavum	lurta
Cheiranthus alpinus Marshalli	Lithospermum prostratum	granulata fl.-pl.
Coronilla minima	Mimulus cupreus	Guthriana
Cytisus Arduini purpureus, &c.	Myosotis palustris	longifolia
Daphne Cœneum, &c.	Orobanchium	Mawiana
Dodecatheon elegans	Jerdoniae	Wallacei, &c.
Mentha Drummondii	Peonia tenuifolia	Sedums (various)
octopetalata minor	Papaver alpinum	Symphytum bohemicum
	Pentstemon nitidus	Trollius europæus, &c.
	secundiflorus	Veronica Allioni
	Phlox frondosa	austriaca
	Nelsoni	Guthriana
	subulata	pectinata
	setacea	rupestris
	s. atro-purpurea	saxatilis
	verna	Grievii

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Terrestrial Orchids.—These, I think, of all kinds should be grown in duplicate collections, each series being rested alternate years by having the flowers pinched out. I examined many dozens of roots of flowering and non-flowering plants of *O. pyramidalis* last week, and, other things being equal, invariably found that the non-flowerers had made the finest new bulbs for flowering next year.—B.

Brodiaea volubilis.—In THE GARDEN of last week (p. 80) this plant is said to be flowering at Kew and at Ipswich, but is described as diminutive in bulk and height. This is not a necessary condition. I have had one flowering in my garden for the last month. The bulb was in the same bed with *Aquilegia chrysantha*, the latter a bushy plant 4 ft. or 5 ft. high. The *Brodiaea* had been neglected and overlooked until, after finding its way to the *Aquilegia* support, it was seen overtopping the stake by nearly 1 ft. It has shown no leaves, but the stem, irrespective of coils, is upwards of 6 ft. in length and the thickness of an ordinary goose quill. I find the stem is now separate from the bulb, having died away from the root upwards; but the flowers are as fresh as ever, supported by about 18 in. of stem, which remain perfectly sound, and apparently there is a prospect that the seeds may ripen.—T. H. A. H., South Devon.

Veronica Traversi.—This highly ornamental shrubby Speedwell is now in full beauty. It is about eight years old, and forms a bush 4 ft. in diameter, and about 2 ft. in height, now completely covered with pure white flowers. It withstood the winter of 1878-9 in one of the northern suburbs of London without the slightest protection, and never lost a leaf. It is a hardy evergreen shrub of close symmetrical habit, and is well adapted for the front of a choice shrubby border, or as a single specimen on Grass. Its leaves, which are arranged in a decussate manner, are of a beautiful deep green colour, and are about the same size, or a little larger, than those of the common Box. The flowers are borne in great profusion upon terminal racemes, and being light and feathery, are well adapted for cutting. A small cluster of these, with a flower of the double Gem and a spray of *Thalictrum*, would be useful where material for button-holes or very small vases is in demand. This plant is one of the easiest possible cultivation, striking freely from cuttings, and not at all fastidious as to soil and situation. I have known it for years, but always had a doubt as to its hardiness. The past winter has, however, definitely settled this matter.—B.

Begonias at the Stanstead Nurseries.—The rapid progress that has been made with regard to the improvement of tuberous-rooted Begonias is admirably shown in Messrs. J. Laing & Co.'s collection, which is now in perfection. Not only does it comprise most of the varieties of merit that have emanated from Continental and English raisers, but also a large number of kinds the result of skilful hybridising and judicious selection practised here during the last few years. A variety of methods of growing them is also well exemplified, especially that of placing them in hanging baskets, or on pedestals, &c., for which some are admirably adapted, as their long, pendulous branches have a very graceful appearance. Large breadths in open quarters are devoted to these plants, and though the present season has not been so favourable for them as previous years, still they are very effective grown as outdoor decorative plants. Although the present season's novelties are very beautiful, and in most cases show a marked advance on the older kinds, yet there are many of the latter still unsurpassed as regards size, colour, and form of flowers. Of these, Cleopatra, Massange de Louvrex, Baronne Hruby, Admirer, J. H. Laing, Marquis de Salisbury, Trophy, are good kinds. The new double-flowered sorts are numerous, and include some strikingly novel colours. Comtesse II. de Choiseul, one of these, has received several first-class certificates during the present season. The flowers are about the size and form of those of the better known Gloire de Nancy, but are of a paler rose hue, changing to a deeper shade as they become more expanded. Clovis is another handsome form, the petals of which are imbricated, and considerably fringed at the edges—quite unlike the other kinds and very attractive. Similar to this is Marie Bouchet, but it has flowers of a deeper tint. Pœoniflora, Clément de la Haye, M. Keteleer, Phosphorescent, and Comte de Flandre, are very distinct kinds, vigorous in habit, and free flowering. The pure white-flowered variety, Reine Blanche, ought not to be omitted, as it is the finest of this colour yet raised, and the same remark applies to a new white double-flowered seedling which has not yet been named, and which, no doubt, will show its character more fully as it becomes more advanced.—W. G.

Common Baneberry (*Actea spicata*).—Although the flowers of this are by no means showy, it is, nevertheless, a very desirable border plant, and one which, on account of its clusters of

deep red berries which stand well above the finely-cut foliage, is at this season very attractive. There are also white and black berried varieties, but neither is so good as the red kind. A group of these interesting subjects at their best may now be seen in Mr. Ware's nursery at Tottenham.

Atkinson's Hybrid Pink (*Dianthus Atkinsoni*).—This hardy perennial Pink is the most brilliant of all the hybrid Dianthus. It grows about 1½ ft. high, and produces a profusion of flowers of 1½ in. across, of an intense crimson colour, the margin of the petals being sharply toothed. A fine specimen of it is now in full beauty in Mr. Parker's nursery at Tooting; it measures 2 ft. across, and the mass of blossoms produced by it is quite dazzling to look upon.

Great Dark-winged Orchis (*O. purpurea*).—Most of our native Orchises are very pretty, and this particularly so. It grows about 1 ft. high, and has broad root leaves from 3 in. to 6 in. long, bright green and spotless. The upper part of the flower-spike has a dark appearance on account of the numerous deep purple bracts with which it is furnished; from the axils of these spring the densely-arranged flowers, which are larger than those of most of the other kinds. Their ground colour varies from nearly white to a rosy-lilac, the lip being of a rosy hue, copiously ornamented with raised deep

Orchis purpurea.

purple spots. As an indigenous plant it is somewhat rare; it is chiefly found in Kent, where it inhabits copses and open woods in chalky soil. For cultural directions and list of other hardy Orchids see page 565, vol. xiii., of THE GARDEN.

National Water Supply.—As a step towards the establishment of a national water supply museum it has been decided to hold an exhibition at the Alexandra Palace during the next few months. This exhibition will be arranged in the following sections:—(1) The physics and chemistry of water; (2) rainfall (including tables of periodical averages); (3) catchment basins, with apparatus for studying percolation and evaporation, current meters, &c.; (4) geology and hydro-geology (including well-measuring apparatus); (5) water-works and filter beds, well-sinking and boring apparatus; (6) distribution of water—pipes, taps, and household appliances, waste preventers, &c.; (7) water examination—chemical analysis, microscopic examination, and examination of clearness; (8) filtration—cistern, table, and pocket filters; (9) hardness in connection with washing, cooking, brewing, and tea and coffee making; soaps in connection with washing; and methods for testing and lessening hardness; (10) water in connection with the spread and origination of disease; (11) antiquarian illustrations; (12) statistical tables; (13) pollution and its prevention; (14) literature; (15) artificially aerated waters and cooling appliances.

MR. KNOWLES, late gardener to Lord Belmore at Castle Coole, has been appointed gardener to G. H. Morrell, Esq., Headington Hill Hall, Oxford.

THE KITCHEN GARDEN.

HISTORY OF THE CUCUMBER.

By H. G. GLASSPOOLE.

THE Cucumber is known to have been cultivated for more than three thousand years. In ancient Egypt it was extensively grown, and is so at the present day; the succulent nature of the plant enabling it to resist the drought of the sandy plains, while it flourishes well in the richer soils watered by the Nile. The want of this vegetable was one of the grievances complained of to Moses by the Israelites in the wilderness; we also find it mentioned in other parts of Scripture. The Cucumber is mentioned in a particular manner by some of the early Greek writers on plants. Theophrastus, writing on the Cucumber, enumerates three varieties—the Beotian, Scythian, and Lacedæmonian; the last, he states, thrives better with watering than the others. We are told that the farmers of those days considered that if their seed was steeped in the juice from the root of the Cucumber it would be protected from the ravages of insects.

Cucumbers grown in the neighbourhood of Antioch were considered by the ancient Greeks the finest. Columella, one of the oldest Roman writers on agriculture, gives directions to his countrymen for forcing this plant by artificial means. Those who wish to have them early, he says, should plant the seed in well-manured earth, put into Osier baskets, that they may be carried out of the house and planted in warm situations when the weather permits. The baskets may be put upon wheels so that they may be brought in and out with less labour, and as soon as the season advances the baskets may be sunk in the earth. Pliny states that in Italy the Cucumbers are small, but in some countries are remarkably large. Those from Africa are most prolific. He mentions that by nature the Cucumber has a wonderful hatred of oil, but has a great affection for water. Of this fact, he says, we may be satisfactorily convinced in a single night, for if a vessel filled with water be placed four fingers distant from a Cucumber it will have descended into it by the following morning—but if the same is done with oil it will assume the curved form of a hook by the next day. This same author tells us that the Emperor Tiberius was so fond of Cucumbers, and took such pleasure and delight in them, that they were served up at his table every day all the year round. The beds and gardens wherein they grew were made upon frames so as to be removed every way with wheels, and in winter during the cold frosty days they would be drawn into certain high-covered buildings exposed to the sun, which was admitted through frames or lights covered with lapis specularis, probably talc or some transparent mineral, which the Romans knew well how to split into thin laminae, so that light might be transmitted through it. This appears to be the earliest account of forcing plants which we read of in ancient times.

The Romans, from the remains of their villas found in this country, appear to have been acquainted with the art of heating their rooms with flues and hot water, and from this we are led to believe that Cucumbers and other vegetables were extensively forced during the days of Roman splendour. Pliny mentions that a new variety of this plant had accidentally been produced in his time in Campania, the fruit of which was of the form of a Quince; it did not grow hanging, but assumed its round shape as it lay on the ground; the seeds from this produced similar plants. The name given to this variety was *Melopepo* (Fée says that this is the Melon, the *Cucumis Melo* of Linnaeus). Pliny appears to have considered this vegetable unwholesome in an uncooked state, but when boiled and served up with oil, vinegar, and honey, it makes a delicate salad; he also recommends a pinch of the seed beaten up with cummin and taken with wine as a good remedy for a cough.

We have no precise date when the Cucumber was first cultivated in England. It may have been introduced with other fruits and vegetables at the time when the Romans were masters of this country. According to a note in Gough's "British Topography," vol. i. p. 134, it was, with the Melon, commonly cultivated in the reign of Edward III. (1327), but in consequence of the wars between the Houses of York and Lancaster the cultivation of Cucumbers, like other plants, became neglected, and at last entirely lost. It was re-introduced at the latter part of the reign of Henry VIII.

Our old friend Gerard mentions them thus in his Herbal (1596): "There be divers sorts of Cucumbers, some great, others lesser, some of the garden, some wild, some of one fashion and some of another. There be also certain long Cucumbers which were first made (as it is said) by art and manuring, which Nature afterwards did preserve, for at first when the fruit was very little it is put into some hollow cane, or other thing made for the purpose, in which the Cucumber groweth very long by reason of that narrow hollowness, which being filled up, the Cucumber increased in length. The seed of this kind being sown bringeth forth not such as were before, but such as art has

framed, which of their own growth are found long and oftentimes very crookedly turned, and therefore they have been called Anguine, or long Cucumber." This old author also gives the earliest direction in this country for making hot-beds for Cucumbers. He directs that they should be covered with mats over hoops, as glasses were not known at that time.

Lord Bacon, who wrote about 1598, says Cucumbers "will prove more tender and dainty if their seeds be steeped in milk. The cause may be for that the seeds, being mollified in milk, will be too weak to draw the grosser juices of the earth, but only the finer." He adds, "Cucumbers will be less watery if the pit where you set them be filled half way with chaff or small sticks, and then pour earth upon them: for Cucumbers, as it seemeth, do exceedingly affect moisture, and over-drinketh themselves, which this chaff or chips forbiddeth." He also states that in his day "it was the practice to cut off the stalks of Cucumbers immediately after bearing, close by the earth, and then to cast a quantity of earth upon the plant that remaineth, and they would bear fruit the next year, long before the ordinary time. The cause may be for that the sap goeth down sooner and is not spent in the stalk or leaf, which remaineth after the fruit; where note, that the dying in winter of the roots of plants that are annual, seemeth to be partly caused by the over-expense of the sap into stalks and leaves, which being prevented, they will superannuate, if they stand warm."

Parkinson, in his "Paradisus," 1656, tells us that "in many countries they do eat Cucumbers as we do Apples and Pears, paring and giving slices of them as we would to our friends of some dainty Apple or Pear." The Cucumber was not generally cultivated till almost the middle of the seventeenth century, and it is stated that the first successful forcer of this plant in England was Thomas Fowler, gardener to Sir Nicholas Gould, of Stoke Newington, who presented a brace of well grown fruit to King George I. on New Year's Day, 1721; the seeds from which they were raised were sown on the 25th of September. Some years ago the Cucumber was cultivated in large quantities in the outskirts of London, and it is stated in Dr. Wynter's "Curiosities of Civilisation" (p. 229) that 14 acres might be seen under hand-glasses in a single domain, and that it has been known that 200,000 gherkins have been eaten in a morning for the pickle merchants. It is also stated that Cucumbers have refused to grow well around London ever since the outbreak of the Potato disease. In London's time large quantities were grown in the fields of Hertfordshire, without the aid of glass, for the London markets during the summer months. The village of Sandy in Bedfordshire has been known to furnish 10,000 bushels of Gherkins in one week for pickling purposes. The Cucumber, notwithstanding its extensive use among all classes in this country, is considered unwholesome by most medical practitioners. Dr. Doran, in his "Table Traits," mentions that in the days of Evelyn (1699) the Cucumber was looked upon as only one remove from poison, and adds that it had better be eaten and enjoyed with that opinion in memory. Abernethy also gave a quaint receipt for its use, which was to peel the Cucumber, slice it, pepper it, put vinegar to it, then throw it out of the window. The extent to which the Cucumber is consumed not only by the inhabitants of Egypt and the south-west of Asia, but also in European Russia and Germany, would scarcely seem credible in this country. A correspondent of the *Daily News*, in the summer of 1874, returning from the fair of Nijni Novgorod, was struck with the profusion of water Melons and Cucumbers every where offered for sale. Pyramids of Melons and water Melons, like cannon balls in an arsenal, were heaped up in every direction, and as for Cucumbers, you could not help fancying that a plague of them like locusts had descended upon the earth. You never see a Russian peasant at dinner but you see the lump of black bread and a Cucumber. The Cucumber seems certainly a singular dish to be so national in a country with a climate like Russia. It is the last that one would have selected a priori for the post; but this is only one of the great many singularities one meets with. The Cucumber costs about the thirtieth part of a penny about the Volga; perhaps this fact will explain the anomaly. Some writer says there used to be a great annual fair at Leipzig for Cucumbers, when the streets were heaped up a story high with that precious element of German cookery. In Germany barrels of half and also full grown Cucumbers are preserved from one year to the other by immersion in deep wells, where the uniform temperature and exclusion from air seem to be the preserving agents.

Nothing can be more agreeable to our olfactory nerves on a hot summer's day than the refreshing and cooling scent of a fresh-sliced Cucumber, but perhaps it is not generally known that in the art of perfuming it finds its way to the toilet table under the form of cold cream and milk of Cucumbers. The large seeds of this tribe are employed instead of almonds in making cheap sugar-plums. Tartary has been assigned as the native country of Cucumbers but upon what authority is equally questionable with that of the Melon. No modern traveller appears to have found it wild.—*Science Gossip*.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Early Cauliflowers.—We are now cutting Dean's Early Snow-ball Cauliflower sown last spring, beating the Early London and other Cauliflowers which have stood all the winter. The last promise to be good, but they will not be in general cutting for another fortnight.—J. M., *Chamber*.

Mushroom Culture in Cellars.—This mode of growing Mushrooms in cellars is very successfully pursued by Mr. Hudson at Gunnersbury House, in the cave-like recesses of an unused cellar, and without the slightest heat except that derived from the stable manure used in forming the beds. In this way large quantities of excellent mushrooms may be obtained throughout the greater part of the year, and it is moreover a profitable mode of utilising such places which often exist in connection with old mansions.—G.

Guano in Wet Seasons.—The effects of guano as a manure on growing crops are most apparent in a season like the present. The ground is now in such a wet state that it almost prohibits one from using liquid manure, and therefore the value of guano becomes most fully felt, seeing that where manure is required one can strew a little of it from time to time over the ground, into which it is washed almost immediately. I have on a cold border some rows of Peas, which some time ago looked sickly, but after giving them some guano in a few days I could see an improvement in them; the same thing happened with Onions and other vegetables. It seems to give a warmth to the soil, which is of great importance this sunless season. Where good guano can be obtained it will hold its own against any kind of artificial manures, plentiful though they be in our markets.—J. C. F.

ANSWERS TO CORRESPONDENTS.

Fruitless Peach and Nectarine Trees.—About three years ago I had my garden wall, which was very old and dilapidated, faced with Portland cement and then wired for my fruit trees. I also use copings during hard frosty weather. The aspect is south. For the last three seasons I have had no fruit, and this year the Peach, Nectarine, and other trees are most shabby. Is there any cause for this except the weather? Are the wires bad for fruit trees? and is it also a mistake to have faced the old wall as I have done? if so, is there any remedy? I should be very thankful for advice.—R. F. C. [Neither cement-faced nor wired walls are injurious. Were the trees injured during these operations, either by trampling the roots, bruising the bark, or allowing cement to get mixed with the soil? If not, then the main cause of their present condition is the bad seasons, three of which we have now had consecutively. The late long-protracted cold and wet have severely crippled many trees that were formerly healthy, hence no wonder that weakly trees have succumbed. I would recommend that the drainage of the border be made effective; next, that all inert surface soil be cleared off and replaced with good fresh loam, and if this be done, and the trees be kept free from aphides, which generally attack them in the earlier stages of growth, and the shoots be kept thin, so as to derive the full benefit of sun and exposure in getting properly matured, then—bad seasons excepted—they must grow and fruit well.—W. W. H.]

—The bad weather is the cause of the unsatisfactory condition of "R. F. C.'s" trees, and not the Portland cement or wire trellis, neither of which, I am convinced, from the lengthened experience I have had with both, are the least to blame for the mischief. We have a wall covered or faced just in the way in which "R. F. C." appears to have had his done, and when the seasons are at all favourable we always get as fine fruit there and as plentiful as we do elsewhere, the only difference being that it is a trifle later in ripening, through the white colour of the cement not absorbing, or attracting, quite so much heat as red brick. There is one important matter in connection with wired walls, and that is, the trellis should be kept close, so as to prevent all draughts behind, as it is these cold currents of air that affect and retard the healthy progress of the trees. The only instance I ever saw in which the wire injured the wood was when it had been tied too tightly, thereby causing great pressure on the bark, and this brings on gumming or canker, which soon spreads and kills the young shoots affected. The only way to preserve Peaches and Nectarines in health, whether on walls or trellises, is to keep them perfectly clean, and afford them proper protection from the inclemency of the weather early in spring. Trees are nowhere looking well this season, as they not only got injured by frost, but they have been paralysed with cold and wet ever since, and it is hardly to be expected that they will have time now to complete their growth and properly ripen their wood.—S. D.

Buckland Sweetwater.—Could you give me some advice as to the treatment of a Vine which I have? It was planted four or five years ago, and the sort is Buckland Sweetwater. In the same house there was planted at the same time a Black Hamburgh which has always done well, and last year carried and finished well sixteen bunches. Now to my surprise the Sweetwater has never even showed fruit; it makes a fair amount of wood, which always gets well ripened. I have seen somewhere that this Grape is considered to be a shy bearer; it certainly has proved so with me. Now what is the best course to adopt? could it be inarched with a vine known to be fruitful? A friend of mine has one which is particularly so, and although he has seen mine the only answer I get from him and others is, they see no reason why it should not fruit. Hence my appeal.—A. PEARL-FLEX OXE. [The Buckland Sweetwater is one of the very few varieties of Grape Vines that bear best as it gets old, so do not get impatient, it will yet serve you well; but meanwhile do not prune too closely, cut back to the plumpest eyes only, and these will be certain to produce "shows." Of course by this system of pruning ugly spurs are created, but what of that if fruit be obtained? Besides, it is a very easy matter to run up a new rod occasionally to replace these.—W. W.]

Window Flowers for Winter.—We are afraid that the list of plants suitable for the purpose named by "Rose" (p. 94) is a somewhat restricted one. It is difficult to have much flower in winter without the aid of heat. Hardy succulent plants such as many of the Cactus tribe, *Echeveria secunda* and

secunda glauca, *Sempervivums*, *Rochea falcata*, *Aloe variegata*, &c., make good plants for windows in winter; so do *Aralia Sieboldii* and many dwarf evergreens. Cuttings of zonal *Pelargoniums* taken now would grow into size by autumn, and probably flower if the weather was sunny and warm; but warmth is necessary to expand their flowers. Such varieties as *Vesuvius*, *Madame Vanher*, *Christine*, &c., are suitable for the purpose. Some late-rooted cuttings of *Chrysanthemums*, seedling plants of *Primula sinensis*, and *Cinerarias* would do. Alpine *Auriculas*, *Polyanthuses*, and *Primroses* would be very useful for spring; but it is too late to sow seed now, and get the plants into a flowering size by spring. Of common seeds sow a little *Candytuft*, *Nemophila*, *Limnanthes*, *Silene pendula*, *Sweet Alyssum*, *Eschscholtzia*, &c. The variegated American *Cress*, *Daïses*, dwarf *Sedums*, and *Ivies* ought also to be tried. Zonal *Pelargoniums* during winter require to be kept warm and moderately dry. All window plants are greatly helped if the leaves be sponged over occasionally.—R. D.

Diseased Peaches.—What is the matter with the Peaches which I have sent? They have been planted in an inside border four years, and have always done remarkably well until this season. The disease first began in one tree; the first sign was a brown speck, then the bit came out of the leaf and left a hole; it began at the bottom of the tree and went upwards, and from one tree to another. Some of the fruit became as if pricked with a pin, and a kind of gum oozed out. The trees have until recently been quite free from red spider; but, owing to trying drier treatment, I see there is a little on them now. The leaves come off as badly as in autumn. There is a good crop of fruit, but I think it would be better taken off, so as to save the trees. I have examined the roots, and they seem quite healthy.—A. G. [Your failure is attributable to a soured and stagnant state of the border. We had the self-same disease in a late house four years ago, and cured it by lifting the whole of the trees, and making an entirely new border; since then, though the same trees were replanted, there has not been the slightest indication of disease. I would recommend the adoption of the same remedy in your case, making free use of drainage and of lime scraps and charcoal in the soil. If the operation be done carefully early in October, the trees will fruit next season, as well as if they had never been moved.—W. W.]

Gooseberry Caterpillars.—How am I to get rid of these? My Gooseberry bushes are quite ruined by them.—CONSTANT READER. [There are various ways of getting rid of these caterpillars, the most effectual at this season being that of dusting them over with Hellebore powder; which being of a poisonous character should be well washed off by the garden engine before using the fruit. Prevention, however, is better than cure; and a good dressing of lime, forked in or scattered over the ground in autumn or winter, prevents the grubs from hatching; and if used with soot or manure as a mixture, it is of great benefit to the land. I used to be much troubled with caterpillars, but since I have adopted the above-named remedy, I have not seen one in the garden. A smart shake of the bush will bring numbers down, when they may be killed on the ground by the back of a spade; and these left on the leaves picked off by hand. Anyhow, they should be exterminated at once by one or other of the means mentioned, so as to get rid of their further increase.—J. S.]

Early Beatrice Peach.—I should be much obliged if some of your subscribers will give their personal experience of this Peach; mine is that, though about five weeks earlier than the best mid-season Peaches, it is quite worthless. Rivers's Early York seems also a very inferior Peach. Dr. Hogg, three weeks earlier than the above, is of very fair size, good colour, and of excellent flavour.—A. SUBSCRIBER. [In what respect is it worthless? my experience is that, though small, it is a finely flavoured Peach, a most profuse bearer, and the earliest variety known. I prefer Early Louise because it is larger, equal in flavour, and only a few days later in ripening. The faults of both are that they are so tender in the skin, they will not travel well, and are therefore not suited for those who have to send their fruit any distance away. Early Rivers is better than either of the above, being larger in size, firmer in texture, and exquisite in flavour, but it is a week later in ripening than Early Louise.—W. W.]

Imported Orchids.—Some time since I bought several lots of Orchids as imported, principally *Celogynes* and *Cymbidiums*. These are now making young growths, but do not seem to be pushing roots. Should they be potted when the shoots begin to grow, or should I wait until new roots show themselves? To any experienced Orchid grower who will answer this question I shall feel deeply indebted.—W. B. [Pot them at once, as in both cases roots proceed from the base of the young shoots, and it is very important that these young roots should have something to run into immediately they come forth. Allowing imported *Celogynes* and *Cymbidiums* to lie about is a mistake; they should be potted immediately it is possible to distinguish deal portions from those that are alive.—J. C. SEYERS.]

Transplanting Bracken.—I have a piece of woodland, into which I want to introduce Bracken. The soil is healthy peat, subsoil sandy. What is my best mode of procedure?—G. S. [Carefully dig up some of the black underground creeping roots and replant them thickly at about 3 in. deep. In digging the roots up care should be taken to select only those which have a green bud at the tip, as without it the roots will not sprout. The best season in which to carry out the operation is March or April.—G.]

Water Lilies.—How am I to plant Water Lilies in a running stream? and what sorts would you recommend me to plant, and when?—P. B. [Water Lilies or any kind of deep water plants may be planted in baskets in sufficient soil, and weighted at the bottom with stones. There are no better kinds than the common native Water Lily (*Nymphaea alba*), and its varieties, especially the Rose-coloured kind. The North American sort (*N. odorata*) is also a desirable kind. Though not so hardy as the common Water Lily, it has the advantage of its blossoms being sweet-scented. There are several other kinds, but as they are somewhat scarce and closely resemble those mentioned, it is not necessary to enumerate them.]

Woodlice (p. 94).—Woodlice seek dry shelter, and may be readily entrapped by laying flower-pots on their sides, containing a wisp of hay or straw and some pieces of boiled potato as a bait. Every morning they should be emptied out and destroyed, either by throwing them into hot water, or casting them to fowls, which are very fond of them. Toads, too, are capital aids in freeing hothouses from these pests, but they cannot be expected to effect a quick clearance. Being much like Beetles in their habits, I should think they would take the same vermin powder, at any rate it is worth trying, and if they should devour it, that would get rid of them at once.—S. D.

Heating (p. 94).—The cheapest and, according to my opinion, the best mode of heating is to use the large, square, or other shaped rain-water gutters that may be had at a low cost and quickly jointed together by screws and red and white lead. All that is necessary is to build up 4½ in. piers to support them at the joints, so as to keep them firm and immovable. By using these there is no occasion to have a tank, or go to any expense whatever, besides which there is no loss of heat, as these gutters, being up clear above everything, give it off from

every part, and being open at the top, there is no lack of moisture. The only thing with these is that, of course, the pipes connected with the same boiler must be kept on the level of the gutters or rather not above them, as if they were higher the water would run out. To form a covering above on which to place the soil or whatever is used for a bed to grow or plunge the plants in, slate is the most permanent, and answers the purpose best, as it is not only imperishable but is strong and a good conductor of heat. Boards or planks are the reverse of this, and require continual renewal, the warmth and moisture being very destructive to wood when placed in such a position. In making the floor of the bed the slates should be so laid as to prevent steam getting through between the joints, as this is injurious to the roots; at least, it so soddens the soil as to render it unwholesome for them to feed on it. Cucumbers sometimes find their way into the water in tanks, but they like more wet than Melons or most other plants.—S. D.

Lilies and Rabbits.—"J. M." (p. 72) asks for a safeguard against rabbits. Let him try a piece of tarred rope tied to the top of the stake to which the Lilies are fastened. Let the ends of the rope hang loosely to the ground. I have found this a safeguard against hares and rabbits in the case of all kinds of young fruit trees, and it may answer equally well as a protection to Lilies.—J. H. II.

Begonias.—T. H. II.—The flowers of *Begonias* sent, though good, are not superior to other varieties in cultivation. The double white Snowflake is not full enough to be termed a good double, but the pure white single form is beautiful and quite worth perpetuating.

Grapes.—G. H. G.—We see no mildew; it is merely a case of scalding.

Names of Plants.—F. T.—*Pinus excelsa*. G. W.—1, *Erigeron macranthum*; 2, *Veronica longifolia alba*; 3, *Oenothera biennis*; 4, *Iris xiphoides*. *Bourne-worth*.—*Scilla peruviana*. C. B. K.—3, *Browallia Jamesoni* (yellow flower); 4, *Escallonia florida*; 5, *Leucothoa salicifolia*. W.—1, *Crucianella stylosa*; 2, *Viola lutea*; 3, *Campanula rotundifolia*; 4, *Dianthus Carthusianorum*. G. P.—They all belong to the *Noisette* group, except the pink, which belongs to the *Danask* section; but there is not sufficient material to name accurately. H. K.—1, *Lythrum Salicaria*; 2, *Gillenia trifoliata*; 3, *Lythrum trinestrin*. C.—All selected forms of *Larkeps*, but we cannot undertake to name them. D. R.—1, *Malvastrum Munroanum*; 2, *Callirhoe pedata*; 3, *Hypericum empetrifolium*. A. B.—1, *Anemone rivularis*; 2, probably *Crambe palmatifida*. N. E. L.—Next week. E. R.—Varieties of *Iris levigata* (I. *Kaempferi*). S. J.—Apparently *Hydrophyllum virginicum*, but cannot name from such a scrap. *North Devon*.—1, *Oenothera fruticosa*; 2, *Delphinium Ajacis*; 3, *Thalictrum rugosum*. N. B.—1, a species of *Oncidium*; 2, *Odontoglossum hastulabium*; 3, *Kivina humilis*; 4, the common Canadian Water Weed (*Elodea canadensis*). *Essex*.—1, *Hemerocallis fulva*; 2, *Oenothera Youngii*; 3, *Veronica longifolia*; 4, *Veronica longifolia rosea*; 5, *Bletia hyacinthina*; 6, *Catananche coerulesa*.

Question.

Melons Splitting.—In a two-light Melon frame I have at the present time a plant of *Scarlet Gem* and *Lord Beaconsfield* respectively under each light. The fruit on *Lord Beaconsfield* is in a satisfactory state and approaching maturity, while the fruit on *Scarlet Gem* (of which there were four) is split, not from the stalk, but across, showing the pips. The fruit is quite hard. I gathered one two days ago, and then cut it, but it was not sufficiently ripe to eat, although it had become much softer, and this morning I found another fruit split into segments, presenting the appearance of a very full-blown Tulip. Is it of any use allowing the other two fruits to remain on the plant? or should I cut them and start the plant again? Both plants have been treated alike.

Horticultural Implements.—In the remarks (p. 87) alluding to the heavy clumsy wheelbarrows in general use in private gardens, it is seemingly inferred that there is not a lighter and equally efficient barrow made; but that is a mistake, inasmuch as there are several kinds in existence which obviate the objection complained of, and notably the *Tubular Wheelbarrows*, invented by Mr. Peirce, of Oxford Street. These are larger and quite one-half lighter than the ordinary wooden barrow. They are made of wrought iron with a shallow, roomy body, the frames consisting of tubular wrought iron, and the handles of the same material, convenient to the hands, and fitted with wrought iron wheels; or if the noise caused by these is objectionable, wheels constructed of wood can be fitted to them. To prevent rust the entire barrow is galvanised, which avoids the necessity of a continuous application of paint. Another noteworthy point is that the wheel is placed more under the body of the barrow than is usually the case, thereby considerably lessening the weight of the load on the hands of the workman. Similar kinds of barrows fitted with solid iron frames and wooden handles are also made, but these are heavier. With regard to garden ladders I must say those in general use are anything but light and convenient. Quite as efficient ladders as those seen in French gardens are, however, made, though they are not sufficiently known. These are also made and supplied by the firm just named; they consist of tubular wrought iron in 6 ft. and 12 ft. lengths, which fit together in a telescopic manner. They are considerably lighter and stronger than those made of wood, as a ladder 12 ft. long weighs about 16 lb. A modification of this is the convertible step ladders, which are fitted with joints, and so arranged that they may be used as an ordinary 6-ft. pair of steps, and are very convenient. In Peirce's Pole Ladders one side fits into the other, making them much more portable than the ordinary form.—W. G.

Wheelbarrows.—These as made in Middlesex generally partake of an awkward box character, the entire side and handle being made out of a single slab; the handles are deep and narrow, and most uncomfortable in the hands of a workman during the whole day. These barrows are not enduring but collapse rapidly when one part gets loose or decayed. I have a barrow of an upright oblong shape made eight years ago that has done a great deal of work, and that will yet do much more. It is made of Ash with round comfortable handles, and has a 2 in. wide iron wheel. With care such a barrow will last many years, and it is light and pleasant to use.—A. D.

SELF-ACTING FERRY BOAT.

We copy the following sketch of a self-propelling ferry boat from the "American Agriculturist," thinking it may interest some of our readers. It is used in crossing streams in which there is a strong current. The boat is a common flat-bottomed "scow," but it would be more effective with a side-board to be let down the same as the centre-board of a sailing boat. The boat is attached to the guide rope, stretched across the stream, by pulleys and tackles, as represented in the engraving. When the boat is parallel with the guide rope it is stationary; when one of the tackles is let out the boat takes a diagonal position, and, the current striking the side of it, pushes it

Self-acting Ferry Boat.

across the stream. By having long ends to the tackle, which can be fastened to the posts on the banks of the stream, the tackle may be drawn up, even when the boat is on the opposite side of the stream, and be brought over for use without much labour.

LOXFORD HALL.

THE garden at Loxford is one of those which, though somewhat devoid of natural features and elaborate design, has been rendered interesting by means of the cultural skill that has been bestowed on its contents, from those in the shrubbery border to the occupants of the plant and fruit houses. Comparatively small quantities and great variety is the style of gardening practised here, except with regard to the specialities in florists' flowers, such as Picotees, Carnations, Pinks, Auriculas, &c., with which Mr. Douglas is prominently associated. Of these there are large collections, especially of the latter, which occupy several roomy frames, and, it is needless to add, are all making vigorous growth, especially the earlier potted plants. The Picotees and Carnations were growing in convenient span-roofed houses, which are wholly devoted to them. At the time these notes were taken but few blooms were expanded, but the show of buds looked promising, and no doubt they will be in perfection by the date of the special exhibition of these charming flowers at South Kensington. Pinks in outside borders were very gay with their many-coloured blossoms varying from pure white to crimson, and the combination of both colours in the prettily laced varieties, all of which should be grown in every border, was also charming.

The conservatory was very attractive, many of the usual decorative plants being in bloom. Amongst them were fine examples, from 3 ft. to 4 ft. across, of the showy *Kalosanthes coccinea*, forming huge masses of brilliant colour. Seldom is this fine plant met with grown to such perfection, though, on account of its simple culture and adaptability for decorative purposes, it is unsurpassed amongst summer-flowering greenhouse plants. It is very variable in colour; in some the flowers are pale pink, in others deep crimson, with every intermediate shade. Large thriving specimens of *Lapageria* drape the roof and walls of this house, the rosy and white blossoms hanging in graceful profusion. Australian plants and Heaths are grown here extensively. One huge plant of *Erica Cavendishi*, several feet through, and particularly noteworthy, is maturing its growth in the open air.

As is now generally the case flowering plants in stoves and Orchid houses were not conspicuous, though in the latter the lovely *Dendrobium* (*D. McCarthiae*) was in flower; also the beautiful *D. formosum*, which thrives here remarkably well, as, indeed, do all that section of the genus with black-haired stems. Two of the finest *Oncidiums* in cultivation were also beautifully in flower, viz., *O. macranthum* var. *hastiferum*, and *O. Lanceanum*; the latter Mr. Douglas finds to succeed best under basket culture. The cool house class of Orchids were well represented, and we were pleased to note that the hardy *Cypripediums* were receiving special attention, including as they do nearly all the kinds in cultivation. The singular Golden *Satyrinum* (*S. aureum*) from the Cape of Good Hope was in flower, and seems to succeed well in a cool airy house with plenty of moisture, such as that in which the gorgeous *Disa* thrives. A choice collection of Filmy Ferns is an interesting feature, and amongst them are good plants of *Toodea Fraseri*, *superba*, and the elegant new *T. plumosa*, a plant which well deserves to be in every collection. *Gleichenias* are valuable decorative plants, especially the twining-stemmed kinds, such as *G. semivestita*, *microphylla*, &c., of which there are here some admirable specimens. *Adiantum Farleyense*, *amabile*, *gracillimum*, *trapeziforme*, *concinnum*, and its variety *latum* are capital exhibition kinds, and as such they are grown here, also *Davallia Mooreana*, a Fern universally admired.

The Vineries were well stocked with good crops of fruit. One house of Muscat of Alexandria deserves especial notice; it was filled with one Vine only, which was planted outside near the back wall in an oblong border about 4 ft. by 2½ ft., and 3 ft. deep, enclosed by a wall. It is bearing about forty bunches of unusual size, both as regards bunch and berry, and so evenly matched that there is not one but would make a creditable display at an exhibition. Pine culture is practised on a moderate scale, as is also other ordinary indoor fruits.

Hawthorns on the Heights.—During the last few days I have walked from Windermere through Low Wood and Troutbeck to the top of Kirkstone Pass, and thence down by way of Ambleside. I shall probably haunt the region for some time to come, in order to enjoy the flowering of the Thorns. There are thousands of these on the roadside and on the slopes of the fells, and you can trace them to the top of the mountains, where they are stunted and deformed, and scarcely yet (July 19) in full flower. But on the lower levels they are full out, and they literally make the wilderness to blossom as the Rose. Some of them are dense masses of the purest white flowers, but very many have flowers of a soft creamy-pink, and a few are warmly tinted with a pleasing rose-pink. Between this date and the 1st of August these thousands of Thorns will be at their best as regards flowering, and when their berries begin to ripen they will make the mountains glow as with fire.

The Lady Fern.—Probably the finest display in the British Islands of the lovely *Athyrium Filix-femina* is to be seen on the route from Troutbeck to Kirkstone, where occur the thousands of Thorns referred to above. The botany of this region is peculiarly interesting, but the Lady Ferns dominate in the undergrowth and constitute a very powerful feature. They extend as it were in grooves or avenues for miles, and generally speaking the growth is superb. I measured one frond and found it over 40 in. in length. The soil in which the finest tufts are found is scarcely more than moderately damp at any time; on the other hand it is never dry, for the frequent fine flowers peculiar to the district keep the vegetation bathed in moisture. The Lady Fern is often planted in wet soil, but we never so find it in the places where it attains its greatest luxuriance.

Rhododendrons in August.—Any of your beloved compatriots of the great metropolis who in the month of June missed seeing the Rhododendrons in bloom, and are now pining under the pressure of regrets, may recover their cheerfulness by tripping to the lake district, where in the warmer parts Rhododendrons were not fairly in flower until the middle of July, and in the colder places will be just about right in the first week of August. On the 26th of July I saw some very fresh and flowery clumps in that glorious valley at Millbeck, which makes a world of its own under the dark shadows of the Langdale Pikes. All Rydal and Grasmere way, all Patterdale and Pooley way, and all Mardale and Hawes Water way, there will be splendid displays of Rhododendrons up to the middle of August, but by that time they will be quite over Windermere and Coniston way. Nine-tenths of all the Rhododendrons in these districts consist of *R. ponticum* of a somewhat common type, but they grow so freely and flower so grandly that one scarcely desires anything better. But, as a matter of course, the gardens that show us valuable coniferous trees and highly-kept lawns and parterres, can also show us hybrid Rhododendrons of the finest pattern; and the man who would gladly go mad upon the subject should pitch his tent near one of the lakes, and then proceed to play the prodigal son in riotous Rhododendronism.—*Gardener's Magazine*.

"This is an art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare*.

GOLDEN YEW.

SEEDLINGS AND GRAFTED PLANTS.

GOLDEN Yews of different types are favourites for planting for ornamental purposes, their shining golden foliage producing a striking effect anywhere in conjunction with other shrubs. They are propagated by grafting in the case of named varieties, but the golden Irish and pyramidal golden Yew come true from seed as regards colour, and I think there can be no doubt that seedlings will make by far the handsomest plants, and where planted for specimens, as they frequently are in parterres, they are every way to be preferred. Grafted plants can only be kept in shape by training and clipping; but seedlings grow of the desired shape without assistance, and also look less formal. Perhaps a good deal is owing to side branches being selected for grafting, but, whether or not, it is a fact that the grafted plants which one generally sees are one-sided or mis-shapen in some way. I was particularly struck with this fact the other day in looking over a collection of some 7000 golden Yews, of all shapes and sizes, in the Handsworth Nurseries. Many of these were grafted specimens, but they could not compare with the seedlings, which varied a little in habit, but in every case formed shapely bushes, and many of them were perfect models of symmetry. The seedlings are, too, by far the best growers. Wherever such subjects are planted on open lawns the seedlings are undoubtedly to be preferred. I am acquainted with not a few pretty old grafted trees in private gardens that look at this day just as they did when planted, and that is like a bushy side-branch stuck into the ground. Such trees rarely or never make a leading shoot, but continue to push branches in a horizontal direction—making disproportionate lateral development and no top to speak of. Some grafted plants of the golden-leaved variety growing in favourable exposures here on the lawn, and planted some years ago, exhibit this tendency in a remarkable manner. They have made dwarf, squat bushes, and will never be anything else apparently. One tree measures 6 ft. across to the extremities of the branches and 18 in. in height; a second measures 11 ft. across by 2½ ft. in height; while a common Yew, propagated in the same way, measures 15 ft. across and is only 5 ft. high. For forming a hedge quickly Yews of this habit are excellent, as they naturally grow close to the ground. Probably this habit of grafted specimens results from the propagation of side or branch shoots more than from leaders, but on that point I offer no decided opinion. The great supremacy of seedlings over grafted plants is, however, worth pointing out in the case of all such habited plants.

J. S. W.

FAMOUS TREES OF HERTFORDSHIRE.

By THE REV. CANON GEE.*

THE Beech is expressly said by Cæsar not to have been found in Britain, and its Welsh name, "Fawydd," is taken to be an adaptation of the Latin *Fagus*. Indeed these, our old Roman masters, are thought to have naturalised here the Chestnut, Lime, Sycamore, Box, and Laurel. But they do not lay claim to have introduced the Oak, and we may safely declare the Oak to have been English in pre-historic times. No one can doubt that it thrives well with us and takes a giant's grip of our soil. It is said that even Americans, accustomed to the giant trees of their forests, yet find an unmatched stateliness and grace in the English Oak. Our climate suits it. No one ever heard of an Oak as being affected by the severity of a winter, whatever that severity may be. We may say of the Oak that its gnarled and knotty trunk is engendered by the rigours of our Northern skies. So very long has the Oak been among us that we are scarcely aware that he seems to have had an elder half-brother; at least, that much of the oldest Oak timber in this country is not of the same kind as that now in use. What we call Oak timber now is the wood of the *Quercus pedunculata*. This has its fruit stalked and its leaves sessile. The other Oak, the *Quercus sessiliflora*, has its fruit sessile and its leaves stalked. This latter is the Oak which furnished timber to some of our oldest buildings—notably to St. Alban's Abbey and to Westminster Hall. The old wood is so far unlike our modern notion of Oak timber, particularly in the absence or indistinctiveness of the silver grain, that it was long considered to

have been Chestnut. Now, the distinction which I have just laid down seems to be recognised and to entitle this old timber to be called Oak. I may mention here that at the hospital of St. Cross, near Winchester, I myself saw Oak of a very singular, dark grain, which was commonly attributed to the way in which the wood was cut. The extreme length of each plank was only 5 ft., and it might all have been cut crossways. A natural question arises at once with regard to the Oak—viz., as to its extreme age. I mean as to the age which it would attain if left to itself, or as to the age of some patriarch of our acquaintance. I do not see how this can be ascertained except by documents, and documents will not go back as far as we desire. Granted that an Oak marks its growth by natural indications, yet when growth ceases these indications stop. I cannot tell upon what grounds the Saley Forest Oak in Northamptonshire is so confidently pronounced to be 1500 years old. We can make no experiments for ourselves in this direction, unless we would repeat the failure of the good old lady, who, having heard that a tortoise would live 100 years, bought a young specimen, that she might judge for herself. I conclude that the only approach to investigation would be to notice carefully the growth of an Oak still growing, and to calculate in what time, proportionally, an old Oak would have attained its girth, and then allow a proportionate time for decay. Of course this growth would vary much from the influence of soil and aspect; still something may be done in this way. Our Lord-Lieutenant, a lover of trees and an observer long before I took up the subject, has given me his experience with regard to trees at Gorhambury. He summarises his conclusions as being, that an Oak increases in girth ½ in. per annum, and a Cedar 2 in. in the same time. But in the memoranda which he kindly furnished there is a difference between the Oaks of which he gave me the measurements. I do not know what experience the poet Dryden had of trees. He most likely gives us the general opinion of his own day in laying down poetically that an Oak's duration is 900 years:—

"Three centuries he grows, and three he stays,
Supreme in state, and in three more decays."

Elms.—I string together a few remarks on other trees generally. I have spoken of Elms as foreigners, but I admit that they were naturalised in the times of the Heptarchy. Like the old family of Coplestone—

"They were at home
When the Conqueror came."

They have given Saxon names to many English villages, as Elmham, Elmwood, Elmsthorpe, Elmstone, Elmstead, and Elmsley. The Elm's failing is to become hollow at eighty years of age, and at that time its arms and roots both become brittle. It has a special beetle to itself called the Elm-beetle (*Scolytus destructor*), and its great value is for such positions as alternate wet and dry conditions, e.g., for pumps, troughs, conduits, water-wheels, and water-gates. If the Elm be originally an immigrant, it has since become an emigrant also. Perhaps it was from his own personal connection with this country that Philip II. of Spain planted the avenues of Madrid with English Elms. Learned men differ as to the origin of the name Wych Elm. There are three derivations proposed. 1. From the Saxon word *wich*, a village or town, as Sandwich, Middlewich, &c. This would make the Wych Elm to be "the village Elm." There is this much to be said in support of the idea, that the Wych Elm does ripen seed; so that it may be thought to have been the earlier or more recognised Elm. 2. From the word *wych*, meaning a box or press, such having been made originally of such wood. Our modern word *hutch* would be a corruption of this, and *wych* is applied in old writings to the ark of the testimony, as also to provision boxes in daily use. We have in old writings "wyches for cheeses." 3. From a superstitious notion that witches frequented this tree, dancing around it or dwelling under it. So far as I can distinguish the original orthography, it seems in favour of the second meaning, which would derive the word from *wych*, a chest or box.

Beech.—The Beech tree peculiarly claims the county of Bucks as its own. In Herts it has more variety in its way of growth than any other growth which I have observed. The Beech close to the Langleybury Parsonage, which seemingly has always stood out by itself, is a model of what a fully-developed tree may become. It scarcely seems to have lost a twig from the first. It was carefully protected in Mr. Whittingstall's time. The hardest thing that can be said of it is, that it is too perfect to be picturesque. An artist would choose a tree more twisted and reflected. At Ashridge you may see the contrary form of elegance which a Beech will take when crowded in its nursery and, as the expression is, "etiolated" by too close proximity to its neighbours. Then it will run up straight as an arrow and upright as a dart. He who does not go to see the King and Queen Beeches at Ashridge does not deserve to sit under trees or biographers of trees. These royal trees, girthing only 11 ft. or 11 ft. 6 in.—the lady is the stouter—ran up, I am assured, 85 ft. before pushing a branch. If you journey thither, mind that you go

* Extracts from a paper read before the Watford Natural History School.

straight to the trunk and stand close up to the very stem. Then look at all the glory of the olive-grey, smooth, clean shaft.

Limes are known by their employment by all carvers, and notably by that prince of carvers, Grinling Gibbons, in the production of his choice works. It is said that the wood is not only smooth-grained and beautiful in its enduring colour of pale yellow or almost straw or creamy white, but that it is also insect-proof. I would inform any one who may lately have had a Lime blown down, or who, as myself, have been compelled to cut down a Lime, that it should not be sold cheap. It is worth at least 2s. a foot as it lies, and is employed to make the sounding-boards and linings of pianos, for which its little tendency to warp makes it valuable.

Ash.—Of Ash I will only say that Gilpin, having pronounced the Oak to be the Hercules of woods, calls the Ash the Venus. I myself always reserve the title of Lady of the Woods for the Birch. Gardeners, it seems, in some places time the planting out of their bedding material by the appearance of the Ash leaf, and remove it when the leaves fall. It is a peculiarly tough wood, and the stoutest oar, tool-shaft, or lance-handle is always made of Ash. But it is considered a dull tree, coming out late and going off soon, and without any bright colour on its rather thin foliage.

Chestnut, whether Horse or Spanish, should always be spelt with a "t" in the middle, in honour of its derivation from Chataigne (French) and Castanea (Latin), both of which words come from the city Castana in Pontus, whence Chestnuts first came into Europe; as Cherries came from a neighbouring town, Cerasus, now Kerasaun. I particularly admire in large Spanish Chestnut trees, as at Ashridge, the twist, as of a rifle barrel, which the bark takes, giving the effect of a spiral column, and making the tree look larger than it really is. I was surprised to find one tree that I measured to be only 14 ft. in circumference. And there is at Abbott's Langley a singular instance that the Horse Chestnut will take root with its branches and spring out again, as does the Banyan, thicker than where it touched the ground. The road having been raised formerly under the large Chestnut on the lawn of Langley House, this process may clearly be traced where the earth has been lifted up until the branches touched the soil. They have taken root and sprung up in renewed vigour. The interest of this tree is so great that it throws literally into the shade the Cedars on the lawn.

Larch, &c.—I might leave out the Larch as a member of the excluded Fir tribe, but I would like to say a few words of this tree as being a tender nurse to the Oak. In the only forest of which I know anything—the Forest of Dean—people prepare for planting, or I fear I may say sowing, Oaks by planting Larches. These spring up soon and form a screen and shelter for the more valuable seedlings. By the time that the Oak can stand alone the Larch is valuable as a pole, and is then removed, to the planter's immediate profit, thus fulfilling the saying that "Larch will buy you a horse when Oak will not buy you a saddle." Still, as Sir Walter Scott says, "Plant trees, good trees, they'll aye be creeping while ye are sleeping."

Individual Trees.—Now I am liberty to notice trees in Herts, famous either for grandeur or story. There are trees famous for their girth, implying age, and generally involving decay. Some of our most venerable friends are mere shells. There are others which stand erect in stalwart strength, and are solid and massive trees. Comparisons are odious; but I think we ought to do justice to the really vigorous and more natural trees, for the greater girth will always be found in those which have been polled or pollarded. I do not want you to look at a tree as do some of my simpler neighbours, in whose minds at once rises the consideration of what it would fetch when down. "I'd be bound to say, sir, that there are four load of timber in that tree. Why, I recollect when a water-wheel at such a mill wanted a new axle-pin, master got £50 for just such a hoak." No; I would deprecate so commercial a view of the glories of our county. I would rather ask you to look at a grand old Oak as Smeaton, the engineer of the existing Eddystone Lighthouse, studied an Oak when the third edifice had to be placed on that storm-beaten rock. Then it is said it struck him that if he could imitate the proportions of a tree which weathers every blast he might hope that his work would stand. He figured to himself a model tree with a real waist, which would encourage the waves to curl over and discharge themselves innocuously. On those lines he built, and the continuance of his erection to this day shows that his labour was not in vain. Well, we will distinguish the old knotted and gnarled patriarchs from these their worthy congeners as best we may. But applying ourselves to take only the girth of a tree we are in some indistinctness, how to measure, or how to compare measurements. At what height shall we take the girth? Shall we be bound to take it at a certain arbitrary height, though not the most favourable to the particular tree? I think not. I understand that we are to get the greatest girth that can fairly be measured, after clearing the root knobs or

earth knots. This, for our own comparison, should be taken as nearly as possible at the same height in all trees. I approve of Lord Verulam's rule of thumb. He always measures a tree at the height of his own waistcoat pocket, he standing on the best side of the tree for a ground level. Do what you will trees will not oblige you by coming into a competition upon terms of exact quality. I have found two trees of which the girth of one was the greater, but it was a hollow sinuous growth, while the less tree met the tape evenly and closely on all its sides, and on that account seemed really the finer tree.

Then, what shall we lay down as our unit of fame? What size shall make a tree famous? I distrust some of the extreme measurements that are given. I have sceptical doubts as to that tree in Hatfield Park, which, according to the *Quarterly Review*, measures 48 ft. in circumference. It is the Oak called the Lion Oak, that tree has been measured for me, and its measurement reported as 32 ft. I myself have never been able to measure more than one tree all the way round that measured more than 30 ft. in circumference. That tree was the Yew in Crowhurst Churchyard, in Sussex, not in Herts. It has a door in the side, and eight persons go in, and, squeezing tight, declare that they are able to sit round it inside. I would suggest that we take 20 ft. circumference as our starting-point, and that we make it our business to be on bowing terms with all trees in West Herts of that girth. You need not be afraid of an inconveniently large acquaintance, while you will not be overwhelmed with everybody else's favourite tree.

The largest tree that I know of, and seemingly the oldest in Herts, is the Spanish Chestnut at Little Wymondley, near Baldock. It is now the wreck of a wreck. There is not a half of its circumference standing, though a print at High Elms, of the year 1790, shows the tree as then perfect. An original girth of 42 ft. is claimed for this Chestnut, and possibly may have been attained, but if so the tree must have projected on the fallen side and would not be anything like a circle with what is left. It is still a grand old tree, and one is ready to believe that it was standing at the time of the Conquest. There is no mention of it, however, in the Doomsday Book of the parish. Next to the old Chestnut at Wymondley, the largest girth that I know is of a pollard Oak in Moor Park, that measures 25 ft. and another near it measures 23 ft. There is also in this park a prostrate Lime mentioned in Johns' book as among the largest in England. It must have been a fine tree, though, like the Codicote tree, its size lay in the space that it covered, rather than in its height or girth. Close behind it, and in the avenue or row skirting the park, is another Lime in full vigour, girthing 23 ft. This is a beautiful tree. There are two Beech trees in Cassiobury Park, going to the Swiss Cottage, both of which reached my standard of fame. Lord Verulam writes me word that the Kennel Oak, at Gorhambury, measures 23 ft. The Queen Oak measures 20 ft., and he has a Lime which measures 22 ft. He gives also as just below my standard (being 19 ft. 10½ in.) the Kess Oak, the origin of which title his lordship thinks is, that the Oak was cased or fenced. By-the-by, do you care to know that the many Gospel Oaks in the country had their names from the fact that, in perambulating the parishes, the Gospel for Rogation Day was formerly read when the beaters of the bounds reached that particular Oak? I will state there is no tree in my list, but examples of it exist somewhere, reaching at least my unit of fame—a girth of 20 ft.

How to Estimate Height.—Now, with regard to height, you may say, "It is all very well to measure girth, but how are you going to measure height?" Who is to tell us whether a tree is 130 ft. or 140 ft. high? I can give you two rules of thumb, which will at least assist calculation. This is one. Supposing your tall friend to stand out well in the open; set by the side of him a stick of ascertained height, say of 6 ft. Watch at the proper hour the length of shadow cast, both by your 6 ft. rod and by the tree. Then calculate in proportion the height of the shadow-casters; e.g., if the tree's shadow be twelve times the length, take its height at 72 ft. Or, take three laths, join two of them at a right angle, and make each lath containing the angle to be of the same size. Then unite the equal sides with a third, subtending the angle. Now hold it level and opposite the tree. Walk away until your eye looks up the third and long side precisely to the summit of the tree. You may now consider yourself to be standing at the apex of an enlarged triangle, of which the ground line is one side and the erect tree another. You measure the ground line, and in so doing you measure the height, for it equals the perpendicular which you thus get. We then tried our triangle upon the tallest tree that I know about here—on the Spruce in the Cassiobury Woodwalks, and found the height to be some 135 ft. Timber trees are not very high if Brown, in "The Forester," be correct in giving the following as the mean average height of trees: Oak, 45 ft.; Ash, 38 ft.; Beech, 45 ft.; Birch, 47 ft.; Elm, 44 ft.; Lime, 44 ft.; Poplar, 48 ft.; Fir, 57 ft.; Chestnut, 44 ft.; Sycamore, 37 ft.; Yew, 16 ft.

The Panshanger and Grimston Oaks.—I have reserved as an example of a tall tree the Panshanger Oak, which is now, I regret to say, "in a very poor way," and not long for its present lofty position. The ground appears to be undermined beneath it. The whole height, as given me by a timber dealer's measurement, is 73 ft., but I distrust his measuring to the very top of what he would call waste. Indeed, another measurement gives twice this, 140 ft., as the extreme height, but that again has not my confidence. The branches, he states, stretch southwards 60 ft., and northwards 35 ft., making a shelter of some 100 ft. in diameter. All accounts agree that it increased rapidly in the later years of its growth. According to Clutterbuck, between 1719 and 1805 it added 480 cubic ft. of timber to its contents. A certain Mr. Barker, timber measurer, of Bishop's Stortford, says that this growth had not ceased in 1795; further, that in fifteen years from 1710 it had increased only 1½ in. The value of the tree, as containing seventeen loads of timber at £15 per load, with top and bark, the valuer, Mr. Ellis, in 1811, places at £225.

There is another and a nearer tree, an Oak of this same character, which I wish to commend to you. It is the Grimston Oak at Oxhey. This tree, insufficiently known, stands a few yards from Oxhey Chapel. It measures 17 ft. in circumference, and 24 ft. in "length," which means, I suppose, the length of its branches. I should have taken it to be about that number of feet to the branches. It was planted by James, second Viscount Grimston, who died in 1773. The tradition of the family, Lord Verulam tells me, is that his great-grandfather planted this tree with his own hands. Supposing him to have planted the tree some twenty years before his death—his eldest son was twenty-six years old at his death—you get a fair idea what a well-grown Oak would become in 120 years' time.

I would like to mention an Ash in my parish, not because of its extreme size, but because I do not happen to know a finer, and because it is a very well-grown tree. It stands at the Hyde Lane Farm, in Abbot's Langley parish, and is 12 ft. round. It has a fine, clear, straight stem, appreciated only by standing directly underneath the tree. It once, I am told, had a narrow escape from the usual fate of trees, becoming the axle of a water-wheel. It then, many years ago, said the old top-sawyer, my informant, contained three loads of timber.

Queen Elizabeth's Oak.—I have now to speak of those trees which, without reference to height or girth, are famous from historical associations. Foremost among these stand out Queen Elizabeth's Oak at Hatfield. Half-way down the avenue leading from the house towards Hertford, and surrounded by a fence, and not in vigorous health, or of a very remarkable bulk, stands this tree, which I myself years ago visited with reverence and brought away a leaf (I would not have broken off a branch) to be preserved among such mementoes of our history. On the morning or afternoon of November 17, 1558—for Mary died between 4 and 5 a.m.—Elizabeth was sitting under this tree when a deputation arrived from the council to apprise her of her sister's demise and to offer her their homage. She fell on her knees, and exclaimed in Latin, "*Domino factum est illud, et est mirabile in oculis nostris.*" "It is the Lord's doing, and it is marvellous in our eyes."

The Boscobel and other Oaks.—Noting the late season of the year, November 17, at which this hardy Queen had seemingly sat out-of-doors, I hope that it will not be impertinent of me to correct here a mistake of which I have certainly heard a young lady guilty with regard to another famous Oak tree. "Ah!" said an accomplished fair one to me on a chilly May morning, when the spring was very backward, "King Charles could hardly have been hidden in the Oak on the 29th of this May." No, my dear miss, nor was he hidden on the 29th of any May. The battle of Worcester, as the battle of Dunbar—Cromwell's two crowning mercies—was fought on September 3, his dying day, and said to be also his birthday until Mr. Carlyle and others produced the entry showing that he was born and christened in St. John's parish, Huntingdon, in April, 1629. The entry into London took place on Charles's own birthday, May 29, and then in memory of the Boscobel transaction the Oak leaves were worn. Of this Boscobel tree, let me say (before I leave the subject) a descendant is said to exist in Gadebridge Park, but my enquiries after the truth of the tradition have been unsuccessful.

I have not quite done with Queen Elizabeth and her connection with Herts and Hertfordshire trees. There is another domain in Herts or its border, only less closely connected with this royal lady than Hatfield. Look into the index to Miss Strickland's "Biographies," and you will find some half-dozen references to Ashridge. I have heard that the house at Ashridge stands partly in one county and partly in another. The parish church, Little Gaddesden, where the Bridgewater family lie buried, is in Herts. Of the Ashes which gave name to that ridge only one remains, as far as I could observe on my visit the other day. Under this tree, or one of its fellows,

we may think the Princess Elizabeth also sat, and so very likely used to sit the *bons hommes* of Ashridge—the hermit priests who formerly owned that beautiful spot, and who lie in the church which the house itself includes. It will be next in chronological order to notice the Oak Wood in Gorbamby. This is a wood at the back of the house specially so called. When Lord Chancellor Bacon was in financial difficulties, it was suggested to him that he should cut down this particular wood. "What! man," said he, "would you have me pluck out my own feathers?" And so the trees escaped, and some, I believe, are now standing. The circumstance is told in most Lives of Lord Bacon, as if it applied to Oaks generally, and they are spelt with a little "o." Lord Verulam tells me that the tale hangs round the particular Oak Wood, as distinct from another, Brook Wood, &c. I come to Moor Park to notice two traditions with regard to trees there. Moor Park was owned once by Cardinal Wolsey, perhaps in virtue of his connection with St. Albans as Abbot *in commendam*. There is a tree which, Lord Ebury tells me, goes still by the name of the Cardinal's Oak. He described to me its exact situation. Lord Ebury thinks that it had its name rather from the fact of the Cardinal's having sat under it than having planted it. It is too old, according to Dryden's lines, to have had its beginning only some 350 years ago. The other Moor Park tradition is as to the beheading of certain trees there. The estate undoubtedly belonged to the Duchess of Buccleuch, who is introduced into Scott's "Lay of the Last Minstrel" (canto i, introduction). This was Anne, Duchess of Buccleuch and Monmouth, representative of the ancient Lords of Buccleuch, and widow of James, Duke of Monmouth, who was beheaded in 1685. And, says the tradition, on her husband's execution, she beheaded sundry of the forest Oaks in the Park.

I would try to enlist on your parts a feeling of conservative preference for the older kinds of trees. I think that our old English trees have got such a character of their own, and give such a character to the landscape, that there is a loss when their monopoly of the fields is largely invaded. I grudge to see some of the foreigners prominently introduced into what I venture to call "our parks." I know a park a few miles hence where the *Arancaria imbricata* is pushing its hard puzzle-monkey branches into the air. *Deodaras*, *Wellingtonias* (or, as they are now called, *Sequoias*) are following up the invasion; and I can imagine these colonial gentry will look down upon Oaks and Elms in the days of our grandchildren. I am aware that this objection is narrow, and a like narrow-mindedness, 200 years ago, would have kept out Cedars. Happily, a passing expression of complaint has little effect either way. I would only press my stricture so far as to urge that large planters shall not introduce these strangers in too large a proportion, and so alter the character of the English forest scenery.

THE DWARF JUNE BERRY.

(*AMELANCHIER CANADENSIS* VAR. *ALNIFOLIA*.)

We have had a single plant of the Dwarf Juneberry for five years, and the more we see of it, the more we like it. In bloom it is as pretty as many of the *Spiræas* which throng every garden, and in fruit it is one of the most luscious-looking shrubs in cultivation. Now, when we can procure ornamental plants—whether shrubs or trees—that are in every way as ornamental as those which do not bear edible fruit, why not give them the preference? *Exochorda* (*Spiræa*) *grandiflora* is a shrub everywhere praised for its beauty. Its flowers are larger than those of our Dwarf Juneberry, and it grows to twice the size, being, indeed, when fully grown, a small tree. But in other respects it is in no wise superior. The leaves of both plants are similar, resembling those of the Pear. Now, the Dwarf Juneberry is in fruit far more attractive than *Spiræa grandiflora* is in bloom, so that counting the fruit as worthless, we should still prefer the former, could we have but one. But the fruit is edible. It is sweet and juicy, and while twice the size of Huckleberries, is not inferior to them. It begins to ripen the latter part of June, and continues for ten days or more. The berries are first green, then nearly white, then red, then purple, and finally, when fully ripe, a dark blue. Often all these colours are seen upon a single raceme and our readers may judge for themselves that when, as at present (July 2), in the specimen before us, a peck or more of this fruit is ripening upon a single bush not over 5 ft. high, it is as ornamental as any plant can well be. We have compared *Spiræa* (*Exochorda*) *grandiflora* with the Juneberry, because they bear a decided resemblance to each other. *Amelanchier canadensis*, the botanical name of the Juneberry, varies remarkably. Gray gives half-a-dozen different varieties, of which ours most nearly resembles *Alnifolia*. We have just selected leaves to show their dissimilarity, and we find the following forms or outlines: orbicular, ovate, oval, obovate, oblanceolate, spatulate, oblong, and elliptical. All are mucronate—some nearly

entire, some finely, some coarsely serrated—some serrated only near the apex, some half-way, and some entirely down to the petiole.—*Rural New Yorker.*

TRANSPLANTING.

The advantages to be derived from transplanting large trees and shrubs are so numerous that they commend the system to the attention of all those who aim at speedy effects in the adornment of their parks and pleasure grounds, or desire to produce immediate shelter or an effective screen. By a judicious application of the system the growth of a lifetime may be anticipated, and situations the most exposed may at once be clothed and rendered attractive. These advantages have commanded for it the attention of eminent men of all ages, as the writings of Pliny, Cato, and Seneca, among the ancients, and the practices of our own Evelyn, of Lord Fitzhardinge (Treasurer to Charles II.), of Louis XIV. of France, and of Sir Henry Stewart in the early part of the present century, abundantly testify. But in some of the cases recorded the outlay was so greatly disproportioned to the results obtained that the practice of transplanting trees of a large size came to be regarded as a luxury within the reach of the wealthy only.

A Greek physician, named Anatolius, who lived in the reign of Constantine, is the first whose writings display an intimate acquaintance with the scientific principles upon which successful transplanting depends. He recommends those who would "remove a large tree to advantage, to open around it a very deep trench or pit, not to injure the branches, to leave the whole of the roots entire, to place it carefully in the new pit, covering up the roots with a quantity of good mould or manure." And modern practice has shown that a close adherence to the above rules will ensure success in ninety-nine cases out of every hundred; for, by a proper selection of trees and soil, by careful manipulation and quick removal, and a moderate amount of subsequent attention, it is almost impossible to select the wrong season for transplanting large evergreens, though the end of the summer or the early autumn is undoubtedly the best, and next to that the spring. Deciduous trees, also, may be thus safely transplanted at any time, except just at the height of the growing season. A warm, moist soil, with a careful watering and liberal mulching, will ensure the safety of large evergreens, even though they may be removed in the middle of summer.

The machines employed in the removal of live trees of large dimensions have varied greatly in construction, and as most of them were made to carry the trees in an upright position, they were generally unwieldy in size. That employed by Louis XIV. in transplanting trees from Versailles to the Bois de Boulogne was long afterwards shown as the wonder of its age. The transplanting machine of Brown, a celebrated landscape gardener of the last century, was among the first constructed to carry the trees in a horizontal position; and it was with a machine of this kind that Sir Henry Stewart effected the wonderful transformation in his park and grounds at Allanton, in Scotland, somewhere about the beginning of the present century. In construction, his machine very much resembled the "janker" or "jigger," now so extensively used in clearing falls of timber. It consisted of a long and strong pole fixed to an iron axle, and mounted upon high wheels. At the opposite end of the pole was a small wheel which worked upon a pivot, and which was removable at pleasure. After the tree had been properly prepared, the machine was brought alongside and placed upright against the trunk, to which the pole was firmly lashed. By affixing cords to the extremity, the tree was somewhat forcibly wrenched from the soil, occasionally at the expense of a considerable number of its roots and smaller fibres. A horse was then attached to the axle of the machine, the roots and branches being tied up to prevent further laceration, guide ropes were put on, and the tree was moved into its new quarters.

Though great success attended the dexterous use of the above machine, preference is now generally given to those which remove the trees in an erect position, with either a small or a large ball of earth

attached. In the practice of Brown both the head and the roots of the tree were much cut away and mutilated; in that of Sir Henry Stewart both were left as entire as possible. In the latter case a trench was opened at a considerable distance from the bole, and by means of the "tree-picker" the soil was carefully removed from between the roots, which were afterwards wrapped up to preserve them from injury. The tap-root was severed, and some of the other large straggling roots were cut away.

For the safe removal of trees with either large or small balls of earth attached, the machine shown in the accompanying illustration is admirably adapted. A represents an end view, B a view of the machine from above, and C a side view with the tree in position for removal. These illustrations so clearly show the principles of the construction and working of the machine that a lengthened description is unnecessary. In order to obtain a proper command of the ball a trench is opened out around it at a distance proportioned to the size of the tree, and of sufficient depth to undermine most of the roots. Iron bars are next driven underneath the ball parallel with each other; stout packing boards are placed around the ball and well braced together; chains are attached to the bars and guide ropes to the trunk of the tree or the lower branches; the windlasses are put in motion; the tree being raised high enough to enable it to travel safely over the land, a horse is put into the shafts, and the machine with its load is brought immediately over the prepared site, when the whole is lowered into position, the boards and chains removed, and bars withdrawn. In this manner trees of from 12 ft.

to 15 ft. high, and 8 ft. to 10 ft. in the spread of their branches, may be removed with a small ball; and others from 15 ft. to 30 ft. in height, with a proportionate head, with a large ball. It may scarcely be necessary to observe that to prevent accidents all materials used in chains, ropes, &c., should be of the best quality. In raising trees with a large ball stout planks should also be placed under the wheels of the transplanting machine, which may otherwise sink deeply into the soil. The conditions upon which the successful transplanting of large trees mainly depends are—1st, selection; 2nd, preparation; 3rd, removal; 4th, replanting; and 5th, and by no means least, after treatment.

I.—The selection of a tree is not less important than that of a suitable soil in which to place it. And the future growth of the tree will depend very much upon the nature of the subsoil. If possible, no tree should be removed into a poorer soil than the one in which it was reared; but, by a proper preparation of the land, by trenching and drainage, and a liberal use of good composts, defects in the soil may to some extent be remedied. For situations of considerable exposure, such as those generally occupied by single trees, a tolerably stout trunk with a fair thickness of bark, a compact and good-sized head, and abundance of fibrous roots, are the main essentials. Without most of these protecting properties vigorous growth cannot be looked for.

II. Trees intended for removal from sheltered spots should be so opened out and exposed beforehand as to secure a gradual thickening of the bark and a hardening of the sap vessels, as well as a proper density of head. Then a trench should be cut round them at a sufficient distance to preserve a considerable portion of the roots

B.—View of Transplanting Machine from above.

A.—End view of Transplanting Machine.

intact, such trench to be afterwards filled up with a good and moderately light compost. In the course of two or three years this will be filled with an abundance of fibrous roots. At the same time some good manure may be scattered over the whole space between the trench and the trunk. If the head requires any pruning to balance it, now is the time to perform the operation; but the less the cutting of branches the better for the tree. A proper preparation of the soil consists in a thorough trenching and draining where necessary, with the addition of some quicklime and clayey matter for light lands, mild lime and sandy soil for the aluminous, and quicklime with peat Moss for loamy lands. But where the transplanter has the advantage of a soil combining the adhesiveness of the aluminous with the friability of the siliceous he is fairly independent of all previous preparation beyond holing for the reception of the tree.

III. During removal the greatest care must be taken not to injure the head, break the bark, or unnecessarily amputate or lacerate the roots. A trench should be opened outside that previously cut round the roots, so that the newly-formed fibrous roots may be taken up uninjured. Where the janker is used and the roots are laid bare the greatest care should be taken to preserve them as entire as possible, and as the unbearing proceeds the smallest fibres should be carefully handled and turned in towards the trunk. When the tree is removed with a ball of earth every precaution should be taken to get well under the roots, to secure all, packing as tightly as possible, and to move slowly and carefully over the ground.

IV. The soil below should be well consolidated before the tree is lowered upon it, and if the bed be made slightly concave or somewhat disked so much the better. All straggling roots should be carefully arranged by hand, and torn ones cut off with a clean section. Where the tree is removed without the ball, the soil thrown in among the roots should be finely pulverised, and only small quantities added at one time, the roots being arranged in tiers according to their positions upon the column. In order to fill up all spaces, water may from time to time be dashed on with considerable force. This will carry the fine earth underneath better than either treading or ramming. With a well balanced head a tree properly placed will seldom require the artificial support of stakes and cords. The thickest and heaviest side of the head may with advantage be turned to the principal exposure. A good ramming after the turf is laid on will be beneficial.

V. Mulching will generally be found the best after-treatment for trees of a large size. Too much watering often does mischief, but when applied it should be thoroughly done. The roots of the Oak, Beech, Birch, and some other trees are very susceptible of drought and of frosts after removal. Wherever upon very wet and retentive soils the trees are at first merely pitted or holed in, the spaces around should receive a good trenching during the following season to permit of the extension of the rootlets, and provision for carrying away redundant water should be made at the same time.

Puckley, Kent.

A. J. BURROWS.

EVIL RESULTS OF FOREST DESTRUCTION.

The immense rush into the great Wheat fields of the north-west of America is justly a subject of gratulation for a hungry world; but do the people of the United States in general, and of Minnesota in particular, understand what the effect is likely to be on the forests, which are so essential to the welfare of every civilised country? The people scattered on the limitless prairies understand very well that forests are not created in a day, and that it is far easier to preserve those already grown than to raise new ones. Minnesota has now probably 10,000 square miles of forests, growing on lands not otherwise considered very valuable; but the fact that they have produced, and are still capable of producing, good timber, shows that these lands are by no means the least valuable part of the State. Are they now being justly dealt by? This is a question of national importance, and one vitally important to the inhabitants of the prairies. To any one who visits a logging camp in the north-western or central part of the State, both the present waste and the future danger are obvious. Two-thirds of every tree felled for lumber is left where it falls, to become kindling wood for future forest fires, destined to consume from ten to twenty times as much timber as is floated down the rivers. This process has only to be carried on a few years to make an end of the lumber business, and leave nothing but tall blackened stumps amid herbage and brush, which gradually become overgrown and formed into prairies. Of all graveyards, there is none so doleful and desolate as a cremated forest. In a hundred or more years it may become a smiling Wheat field, but in the meantime it remains an awful monument of human folly.

The Government creates a railroad corporation, endows it with timber land, and allows it to ravage as it pleases, at the risk of burning up all that the Government itself desires to retain. Government officers take some pains to stop the stealing of timber, but they adopt no satisfactory measures for the preservation of the forests, though every square mile would well repay the salary of a man to watch it, and see that nothing is either wasted or burnt unnecessarily. The forests of the State are generally interspersed with lakes and meadows, furnishing abundant food

for cattle, and in these forests settlements might very easily be formed, which, by the aid of the animals in keeping down the luxurious growths of Grasses and Watercresses, would preserve the young-growing timber on the public lands from destruction either by fire or by irresponsible marauders. Such settlements should be in sufficient numbers to use up or export for fuel all those parts of trees which are not considered fit for the saw-mill. By a wise and efficient policy of protection, the forest lands of Minnesota would support a considerable population, and supply a continually increasing amount of the most valuable building materials for Nature, with a little assistance, always improves upon herself, and though it is impossible to conceive any subject more worthy of the immediate attention of the enlightened and thoroughly scientific representatives of the people, they at the present time have not been sufficiently aroused to the importance of preserving what purifies the air which men breathe,

C.—Side view of Transplanting Machine with tree in position.

prevents the rivers from drying up, repairs and mainly builds the houses, and supplies fuel for the inmates. History records numerous instances of countries rendered uninhabitable by being denuded of trees; and years ago Lindley adduced many cases from France of the wells of a whole district drying up, Olive crops failing, inundations occurring, and many other calamities following the reckless destruction of forests.

A. J. BURROWS.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

The Snowdrop Tree on Light Soil.—Mr. George Paul informs us that a small bush of this tree has flowered freely in his nursery at High Beech, where the soil is light; whereas in the Cheshunt Nurseries, in the richer and stronger soil, old specimens of the same tree have never bloomed. We have before noticed the tree flower well on poor light soils. Perhaps this has something to do with the fact that it is so seldom seen for a tree of such singular beauty.

Moving Hollies.—Apropos of the moving of Hollies, it may be interesting to note that a number of these plants, which were sent to the Agricultural Show at Kilburn by Mr. George Paul, and which remained there ten days or so, look now quite healthy in their quarters. The changes were equivalent to two transplantings at midsummer.

Leafage of the Oak and Ash (p. 86).—Did any one ever know the Ash in leaf earlier than the Oak? I have not. I have watched the two trees for many years, and have always found that the Oak is earlier than the Ash by one, two, or even three weeks. It should be remarked that where the Oak can root deeply the Ash can do the same; therefore, the same influences operate upon the roots, and consequently upon the trees in either case. As a rule, too, it is found that trees are more susceptible of leaf action than of root action, or, to put the case more clearly, of leaf influences than of root influences. This is seen in the case of a plant that has its head under glass and its roots in the open air, the extra warmth found in the house promoting growth weeks earlier than would be the case if both head and roots were in the open air.—A. D.

Magnolia grandiflora.—This is undoubtedly the finest of all our wall or pillar plants. The south front of the mansion here is completely covered with creepers, but towering above all, and clothing the lofty pillars that support the central porch, is this Magnolia, beautiful as regards its shining foliage even in the depth of winter, but doubly so now, when covered with masses of buds in various stages of expansion, quite loading the atmosphere with fragrance. Unlike many of our most showy climbers, that so quickly fade, owing to their blooms all expanding simultaneously, this Magnolia continues to expand for many weeks in succession; in fact, the autumn frosts generally cut off the latest crop of blooms. I am well aware that many complaints of flowerless Magnolias are heard annually, and I would recommend any one wishing particularly to flower this fine wall plant to note the conditions under which ours succeed so well. They are planted in the soil under our terrace walk, which, from constant traffic, is as hard as soil can possibly become, and, being a naturally clayey loam, it takes the stoutest of tools even to move it when once it is well consolidated. The aspect is full south, on the steep slope of a hill, so that the sun's rays are concentrated, not only by the huge building behind, but by the hill, clothed with trees, beyond, so as to effectually shut out the north winds. Yet, during the late long winter and still more inclement spring, we had a full share of frost, so that Myrtles, Escallonias, and similar dwarf plants beneath the Magnolia, were very much cut up. But, beyond losing a good many leaves, the result is rather beneficial than otherwise, as the long period of rest has apparently induced a more than usual display of bloom buds.—J. GROOM, *Linton Park, Maidstone.*

Olea ilicifolia.—This is a beautiful evergreen shrub, somewhat like the Holly, with very dark green foliage, and a good close habit. It is perfectly hardy in Mr. George Paul's nursery at High Beech in Epping Forest, and promises to be, and is, a first-rate evergreen. The variegated kind is well known, but this green form is much handsomer, and more valuable for general planting.

Variegated Tulip Tree.—We notice this in Mr. George Paul's nursery at High Beech. The variegation is for the most part a marginal band, which leaves the greater part of the surface of the leaf green and healthy, therefore this is likely to be what is called a "good variegation," as distinguished from those which end in disease or death.

Azalea amœna.—We have long known this pretty little shrub to be quite hardy, although it is so often grown in greenhouses, and so frequently forced; but we have not seen it grown so well as a

hardy shrub as in Mr. George Paul's nursery at High Beech. There it forms neat little bushes from about 15 in. to 18 in. high, and is quite a sheet of flowers in spring. We hear that a white variety of this valuable dwarf shrub is in cultivation, and if so it will be a great gain. The plant deserves a place in the rock garden, as well as among choice dwarf shrubs.

THE FLOWER GARDEN.

PINKS AND CARNATIONS.*

CARNATIONS are said to have been introduced into England in an improved form from Poland by Gerarde in 1597, and 360 distinct sorts are reported to have been grown in this country in 1676. Hogg and Maddock were the first to take up the cultivation of this fine flower with the intention of raising seedlings and producing plants for sale. Good seedlings at that date were few and far between compared with what are produced now-a-days, thanks to cheap glass and other modern improvements of our time. Hogg stated that a florist who succeeded in raising six good Carnations in his lifetime was to be considered fortunate. This, compared with what has been done by such raisers as Headley, Turner, May, Hooper, and others, shows the vast progress that is being made in the production of new kinds—even taking into account that Carnations are not grown nearly so much as they ought to be. Beginners should commence with the most vigorous and cheap varieties, as many of the prize sorts have been propagated from layers for the last thirty or forty years, and therefore much of their original vigour is lost. Carnations should be planted in well prepared ground, into which has been worked plenty of good old manure; in short, the nearer the ground is half-and-half, *i.e.*, half soil and half manure, the better they will grow and flower. They should be planted from 12 in. to 15 in. apart, so as to afford room for layering every shoot, and they should be staked as soon as they start to spindle up, as the flower-stems are very brittle. If for competition, the buds must be thinned according to the strength and character of the variety, and before expanding many of the sorts require a piece of bast tied round the pods, giving it only a single knot, so that as the flower opens the bast slips gently off; they should also have a stiff paper card cut up to the centre put round the bloom, so as to keep it in form. Blooms for competition require to be protected from rain and bright sunshine. Layering ought to be commenced as soon as the flowers are on the wane, and the layers require to be as little handled or dressed as possible. In fact, it is much better neither to clear the shoots of leaves nor cut the tops off the foliage, but just to give the stems a nick half-way through and then turn up the tops for $\frac{1}{2}$ in. or so. After pegging them down, cover with $\frac{1}{2}$ in. of sharp pit or river sand mixed with a little fresh loam, and give them a slight watering through a fine-rosed watering-pot every evening when the weather is dry for two or three weeks. If layered early, they will be rooted in three or four weeks, when they can be removed and the strongest planted out in beds. If the winter is very severe, they should be slightly protected with branches, mats, or a slight mulching of stable litter. The smaller plants can be potted for sale, and if for home use they may be kept either in small pots or set in cold frames close to the glass, where they can at all times have plenty of light and air during winter; nothing is worse for them than a close frame or house. The frames in which I have wintered thousands of plants have had a current of air blowing through a ventilator 1 in. wide back and front under the sash, even when the thermometer indicated 22° of frost; and yet I have not lost a single plant, and have not had a single spot visible on the foliage of any of the plants thus treated.

Modes of Raising Carnations.—If from cuttings, they require to be about 3 in. or 4 in. in length, and they should be put into pots or a cold frame in very sandy loam, and not subjected to much heat. They should, however, be supplied with plenty of water, shaded, and kept close for a few weeks. If put in a cold frame in September they will be found well rooted in spring. Tree Carnations, a class of the greatest use for winter, spring, and early summer decoration, are best raised by means of cuttings. They can either be grown in pots or in a cool greenhouse border, where they can be subjected to plenty of light and air; and, for winter work, a little fire-heat will prove beneficial. In this class there is no lack of fine varieties, thanks to the labours of Mr. Robertson, Seacot, Leith, who has raised many thousands of seedlings, and who has been fortunate enough to have secured a number of gems of various colours (both selfs and stripes). If raised from seed, they should be sown in pots or in a cold frame in May and June, and the

* Read at a late meeting of the Scottish Horticultural Association, by James Grieve, Pilrig Park, Edinburgh.

young plants should be pricked out when about 2 in. in height. These will make bushy plants fit to plant out in September; they will stand the winter with a slight protection, and flower the following season. All small and weak seedlings ought to be potted and kept in a cold frame, as it is very often the case that the finest varieties are obtained from such seedlings.

Enemies of the Carnation.—Wireworms must be carefully sought for at potting and planting-out time; Potato or Carrot baits put into the pots or beds should be looked over every day and all the wireworms killed. We have ourselves to blame in some measure for the ravages committed by such pests, as we use all sorts of soil if supposed to be new or fresh. All ground may be considered to be new if none of the same tribe of plants has been grown on it before, and by using plenty of good old manure from a spent hot-bed we can easily make it fit for crops of all kinds.

Classes and Properties of the Carnation.—1st. Flakes, *i.e.*, flowers with two colours, the stripes running through the petals lengthwise; 2nd, Bizarres, *i.e.*, flowers striped with not less than two colours and the ground colour, making in all a three-coloured flower; 3rd, Picotees, which can be either white, yellow, slate, or any other shade, with an edge round each petal of a distinct colour, broad or narrow, the flowers being free from all spots or blotches on the surface; 4th, Tree Carnations, which are profuse flowerers of various colours, and free from all bursting of the flower-pods; 5th, Cloves; this is a class of self-coloured flowers, much admired for their fragrance, profusion of bloom, and hardness; the form of the flower should be half a ball, the petals large, broad, and of fine substance, and quite smooth on the edges; the colours should be rich, clear, and well defined, and the petals smooth and without confusion.

The Pink.

Pinks are considered to have been produced from *Dianthus deltoides* and *D. plumarius*, both natives of this country. They are therefore much hardier and dwarfer than the Carnation, and produce flowers in the greatest abundance. In order to grow them well for show purposes, the ground requires to be very rich and well prepared the year beforehand, and to be planted early in autumn as soon as they can be got rooted after August 12. They can be grown to great perfection when planted 9 in. by 9 in. plant from plant every way. If the winter is very severe, they are none the worse for a little litter being put over them, especially after the new year before the days become long and bright, and cold east winds and slight frosts occur at night. In spring the beds in which they are grown will be much improved by stirring their surface a little, and giving them a top-dressing of fine old manure and a slight dusting of guano. As they push up their flower-spikes they should be staked, and if for competition the buds should be thinned, as a number of varieties produce buds too freely. Flowers for competition require to be shaded from rain and bright sunshine.

Where seed is wanted they should be protected from wet, and as the flowers decay the withered petals should be removed, as they encourage damp, and also form a harbour for insects. Seed requires to be sown early in June in pots, or in the open ground, and saved only from some of the finest and most constant varieties, such as have a vigorous hardy habit of growth. I have found it advantageous to kneec or slightly break the flower-stems, an operation which induces the pods to fill better. Pinks are also easily propagated by pipings or layers. Pipings can be taken off when the bloom is on the decline and put into a spent hotbed or cold frame, where they should be kept close and well watered, and shaded for fifteen or twenty days. I have also been very successful in rooting them in sand and water in flats in a greenhouse or frame. When rooted it is best to prick them off into a frame or store-bed until they are wanted for sale or for planting out. They are easily layered, and layers make strong plants sooner than pipings. Seeds may be sown early in June either in pots, frames, or in the open ground. At present I have between 2000 and 3000 seedlings from 1 in. to 2 in. in height. These I will plant out in August or September, and they will flower the following July, when I expect to be able to select a number for propagation and proving, as seedlings, which look well in the seed-beds, often turn out, when propagated, to be of very little value. Good Pinks should be large, the petals smooth, of fine substance, and very constant in their marking, and not too full, so as to cause confusion and spoil the symmetry of the bloom.

There is also a class of Pinks suitable for forcing of the greatest service to those who require flowers of fine quality and fragrance early in spring or summer. These are all very free flowerers and vigorous and branching in habit. The flowers are both self striped and belted; nor must I omit the Mule Pinks, a class for border decoration too well known to need description. Concerning Alpine kinds, which are principally grown in pots or in the rock garden, I will only mention that *Dianthus alpinus neglectus* and *D. dentosus* are too good to be lost sight of.

Last of all I must say a few words in praise of Sweet Williams single and double. They are generally sown in May, June, and July, and planted out in autumn or spring, and they will flower profusely when a year old. There is a large number of varieties of Sweet Williams in cultivation, but those known as Auricula-eyed are the finest. The heads and pips of flowers should be large and smooth, and the colour dense and bright. There is also a sub-species known as *Dianthus nigrescens*, with very dark foliage and rich crimson self-coloured flowers. Plants of this when in full bloom studded with white anthers have a fine appearance. There are also a good many sorts which are generally propagated by cuttings; the double variety of *nigrescens* is a dwarf and dense-growing plant. From a hybrid which I have raised between the Sweet William and the Pink I obtained some seed, and from this I have raised a number of good and distinct varieties.

MAKING AND PLANTING ROCKWORK.

THE making of rockwork on which to cultivate rock and alpine plants, and also as an example of good taste and variety in the garden, is a labour often undertaken, but one which is very difficult to execute. Legions of examples of rockwork are to be found all over the country—indeed, in most gardens—in more or less good or bad taste, from the offensive heaps of vitrifications from brick and glass works, to the admirable imitations of stratified rocks on a large scale executed by Pulham, with the assistance of the mason's art and plenty of cement. Indeed, so good is the imitation that one might fancy the quarry brought bodily into the garden, as they move houses in America. The best specimens of artificial rockwork are generally to be found where the natural rock and rock scenery are most abundant—where Nature's materials are at hand, and where Nature is near to show the way. The worst specimens, on the other hand, are to be seen where the difficulties of site and materials are the greatest—where the products of the glassworks are pressed into the service, and where the site would be more suggestive of a brick-yard than of a rock garden. I think one grand flower-show at least can be remembered—an international one—where the rockwork was made of coke. Between Pulham, on the one hand, and the coke rockery on the other, there is room for many varieties of the art and mystery of rock making, and the gap is well filled up. When a rockery is to be made, two primary objects should be kept in view. The first is, that the fabric to be constructed shall be pleasing to the eye, and harmonise with its surroundings,—that it should not look toy-like, too artificial or incongruous, but be an agreeable feature in the garden; and the second is, that it be so constructed that it shall be suitable for the growth of the plants desired to be cultivated on it. A rockery may be a first-rate imitation of a real rock or cliff, showing the dips, stratification, and other features, and yet offering but small facility for the introduction of plants, thus favouring one of the objects at the expense of the other—just as magnificent conservatories are sometimes built in which plants can only languish.

In order that a rockery may not be offensive or incongruous the site must be well chosen. Pyramids of stones on a flat surface, an amphitheatre, symmetrically arranged, fronting a shrubbery or in the corner of a terrace, or in any geometrical position adjoining buildings, are instances of positions where rockwork would be out of place. But given an abruptly sloping natural declivity—if adjoining water all the better, and if the aspect can be varied by bending round an angle, better still—there a rockery may be made. The site may even be artificially improved in deepening the slope, by adding to its height with soil or planting. We do not think that it is at all necessary that a rockery should be an exact copy of nature in any of its forms—either of stratified rocks or the many forms in which the detritus of rock is found. A tasteful piece of rockwork may be made without any very close imitation of nature,—just as a landscape can be thrown on canvas by the painter which at once pleases the eye of taste, artificial though it be, by the truthful look there is about it. A certain amount of Nature's guidance must be admitted, as a matter of course; for instance, irregularity and variety, as if by chance, an orderly disorder in which, like Hamlet's madness, "there must be method." The materials must be natural fragments of rock—not water-worn stones, or stones with any indication of the quarry about them: unstratified rock we like the best. These can be so arranged that an endless variety of little terraces and recesses, and pockets and ridges, from base to summit, can be made to suit any variety of plants, from the shallow-rooting Saxifrage to the deep-rooting Gunnera. Overhanging ledges can be made, with recesses for shade-loving plants. In short, in the construction, our second object proposed—that of preparing suitable positions for the plants desired to be cultivated—must ever be kept in mind.

The most of our European Alpine plants require a permanently moist soil, as every one knows who has trudged the mountain slopes

in search of plants, although many do prefer a scanty soil on cool rocks—which means that no position exists which may not be selected by some plant where to live and thrive, as witness the stone-and-lime wall seen from our window, covered with *Aspleniums*, *Scelopendriums*, *Ceterach*, *Drabas*, *Linarias*, and many more things equally green, if with names more homely. Some require the cool moisture of running water always among their roots, as the *Parnassia*, *Narthecium*, or *Pinguicula*; and if a trickle can be conveyed over some part of the rockwork, it will be the one source of success in many instances. Some will require a sharp shingly soil, as the *Dianthus*, which can be supplied in the shape of the smaller broken chips of the rock, giving an opportunity of varying the construction of the surface. Some plants require a stiff, holding soil, such as the *Primulas*, which can be supplied in little flat terraces formed to catch all the rains. Others, as the dwarf *Veronics*, such as *taurica*, will thrive on dry, sloping ledges; the various *Thymes*, *Aubrietias*, *Erodiums*, and some *Geraniums*, are of this class. Many of the smaller shrubs are most appropriate as rock plants. Ivies of the finer class, such as the variegated, may be made to creep over large blocks, or the pretty *Ampelopsis Veitchii* in the same way. *Muhlenbeckia complexa*, which has stood the late winter on the rockery, is a choice plant for fringing a ledge. The *Kilmarnock Weeping Willow*, in a dwarf form, will spread its long, slender branches over some peak, as well as the *Savins* and *Periwinkles*, *Rock-roses*, and *Genistas*, and many more of a woody character.

We have been supposing the rockery to be on a somewhat enlarged scale; of course its extent and form must be determined by the requirements of the owner, and the nature of the position to be occupied. It may be curved either outwards or inwards, it may be of a long ridge shape and undulated, or it may be in the form of a group of hills and valleys, and need not after all cover an extravagant area, or require by any means an extravagant amount of stones. One of the best managed of this last kind which we have seen is in the grounds at Down House, Dorset. Whatever be the shape, if the rockery has any pretension to be anything more than a mere toy by the side of a walk, provision must be made to give access to the different parts, in order to be able to clean it and attend to the plants, and particularly that the owner may conveniently at any time enjoy an examination of his plants. This can be managed by introducing a pathway, curving and undulating about among the different compartments. These pathways can be made a feature of the rockery itself, and far from spoiling its appearance, can be made an improvement. The pathway itself, of course made with pieces of rock, should be planted with *Sedums*, or *Stellaria*, or prostrate *Pyrethrum*, or any creeping plants not easily destroyed. Sometimes a rockery can be made more imposing, if the scale is large, by having groups of the smaller Pines planted on the higher parts, such as *Pinus Pinea*, *Abies orientalis*, or any of the dwarfed, pendulous forms of *Abies exeelsa*, or plants of the common *Sumach*, *Spiræa Lindleyana*, or indeed any of the *Spiræas*, where they would not interfere with the well-being of the choicer plants below. When a rockery abuts upon Grass, it is always well to have a narrow margin of rough gravel following the undulations of the base, for the sake of tidiness.—*The Gardener*.

NEW MUSAS.

IN the "Catalogue of New Plants, &c.," recently issued by M. Salmiati, of Florence, the following Sumatran Musas are announced as being ready for distribution:

Musa sumatrana (Beccari).—This elegant and quite new Banana-tree grows wild in the virgin forests of Sumatra, along with the wonderful *Amorphophallus Titanum*. Its elongated foliage is of a sea-green colour, and even in the young specimens it is elegantly striped with maroon-red. It produces bunches of cylindrical curved fruits, from 3 in. to 4 in. long of the size of one's little finger. Its flowers are unknown; but the species is well distinguished among all those which produce falling fruits, by its flattened seeds, with sharp and irregularly toothed edges. It is a very ornamental plant, on account of its beautiful foliage, and will succeed on the open ground in summer.

Musa troglodytarum.—The name given to this plant is most appropriate, for it is the Banana tree of the first inhabitants of the forests, *i.e.* the apes. The fruits of these plants, which culture has rendered exquisite and nourishing, are filled in the wild state with an innumerable quantity of seeds, which, although enveloped in a small quantity of sweet and agreeable pulp, render them unserviceable for human nourishment. The present species is of the greatest interest; for while those cultivated under the names of *Musa Sapientum*, *paradisica*, *rosacea*, &c., are forms produced by culture, and do not give seeds, this species is still in the primitive state; and those which man has known how to ameliorate and transform into

very useful plants, are doubtless derived from the latter. The seeds have been gathered on Mt. Singalang, in the island of Sumatra, at the height of 5000 ft. above the level of the sea, where the thermometer in the morning fell to + 10° or + 12° (from 50° to 55° Fahr.). It is a species of great scientific interest, and its beautiful form and superb leaves render it ornamental in gardens, since it will contribute much to their outdoor decoration during summer.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Bocconia cordata.—This is a truly noble plant for shrubbery borders or the wild garden. Its beautiful foliage alone has a grand appearance, but when surmounted by tufts of large, feathery, spire-like flowers, it forms a conspicuous and noble ornament to any garden. It is of very easy culture, and when once planted soon increases so as to form large clumps by means of its spreading underground roots. With us it grows from 7 ft. to 8 ft. high; for mixing with large masses of shrubs it is invaluable, as it comes into bloom after most of the flowering shrubs are over, and gives a cheerful look to what would otherwise be a sombre mass of foliage.—J. G.

Sempervivums.—My plant, supposed to be *S. Pomelli* at the late Manchester Show, has at last flowered, and Mr. Baker pronounces it to be *S. arachnoideum majus*. When this plant was first alluded to at St. Alban's Court (Vol. XV., p. 492), it was represented to be a variety of *S. arachnoideum*, with a good deal of red on the rosettes.—E. JENKINS, *Newton Nurseries, Chester*.

Canterbury Bells.—These comparatively neglected flowers are capable of very good effects. We have a good many planted in mixed beds and shrubbery borders, and at present they make a fine display, loaded as they are with large white and blue bells. They should be treated as biennials; and by sowing a bed every year, and transplanting them in due course to their permanent flowering quarters, one may ensure a fine display, let the season prove ever so adverse.—J. G.

Stevenson's Blue Lobelia.—In a season by no means favourable for bedding plants, this has been most effective. We have a double line of it in ribbon borders, two hundred yards in length, and it forms the most brilliant mass of deep blue imaginable. The plants were all raised from cuttings early in spring, putting about 200 in an ordinary cutting box, and as soon as struck hardening them off, and transplanting them into cold frames until required for planting.—J. GROOM, *Linton Park*.

Amaryllis longifolia alba (syn. *Crinum capense album*).—Plants of this fine Amaryllid in the Newton Nurseries, Chester, have withstood the severity of the past winter in the open ground and are now flowering profusely. The flower-stems are some 2½ ft. in height, and on one spike alone I counted some thirty flower-buds, several of which are now fully expanded. It is growing in a deep rich sandy loam, which it seems to thoroughly enjoy. It makes an excellent companion for some of the earlier flowering Lilies and similar plants in the mixed border.—E. J.

The Flame Nasturtium at High Beech.—*Tropæolum speciosum*, of which we hear so much as a brilliant ornament to Scotch houses and gardens, has been grown in a most interesting way in Mr. George Paul's nursery at High Beech. Mr. Paul has a long row of it in the best condition parallel with a Yew hedge. Stakes are leant against the Yew hedge, up which the shoots of the *Nasturtium* grow, and, by-and-by, they will mingle with the Yew. In such a position their wreathed scarlet flowers will be very attractive. The plants are beginning to flower now, and a little later on they will probably form one of the most beautiful of garden pictures.—V.

Ornamental Grasses.—These are now so largely used in the dressing of epergnes, vases, &c., that the committee of the Ealing Horticultural Society do good service to those who have a taste for domestic floriculture, by offering prizes for the best collections of six kinds of Grasses, shown in bunches. It is very evident that wild Grasses, let them be ever so fresh and good, have little chance against cultivated Grasses, as amongst these are many that are very beautiful. The small and exceedingly elegant *Agrostis nebulosa* is one of the most charming; and there are few who would not find it worth their while to grow a few large pots or pans of some half-dozen kinds, thinning out the plants, as with plenty of room the floral heads are much prettier and better developed than if crowded. I think it is worthy the attention of committees of flower shows to consider the desirability of offering prizes for Grasses in pots rather than in bunches, as this would enable the usefulness of many kinds for greenhouse decoration to be fully displayed. Sorts that grow from 12 in. to 13 in. in height would be the most suitable; they should be grown in frames near the light, to prevent undue height, and should

have plenty of water. Wild Grasses are this season unusually fine and abundant. A walk amidst fields and rural lanes, collecting samples in bunches of all the kinds that are worth gathering, would offer to many a pleasant and profitable way to pass leisure hours. Gathered now, they need full drying, and then they may be employed for vase and flower decoration all through the next winter.—A. D.

SCENE IN THE LATE MR. HEWITTSON'S GARDEN AT WEYBRIDGE.

TRUE taste in the garden is unhappily much rarer than many people suppose. No amount of expense, rich collections, good cultivation, large gardens, and plenty of glass will suffice: all these and much more it is not difficult to see, but a few acres of garden showing a real love of the beautiful in Nature as it can be illustrated in gardens is very rare to see, and when it is seen it is often rather the result of accident than design. This is partly owing to the fact that the kind of knowledge one wants in order to form a really beautiful garden is very uncommon. No man can do so with few materials. It is necessary to have some knowledge of the enormous wealth of beauty which the world contains for the adornment of gardens; and yet this knowledge must not have a leaning, or but very partially, towards the dry-as-dust character. The disposition to "dry" and name everything, to concern oneself entirely with nomenclature and classification, is not in accordance with a true gardening spirit.

The garden, of which we here give an engraving from a sketch by Mr. Alfred Parsons, contains some of the most delightful and original bits of garden scenery which we have ever seen. Below the house, on the slope over the water of Oatlands Park, and below the usual lawn beds, trees, &c., there is a piece of heathy ground, a portion of which is shown in our engraving, and which when we saw it was charming beyond any power of the pencil to show. The ground was partially clad with common Heaths with little irregular green paths through them, and abundantly naturalised in the warm sandy soil were the Sun Roses, which are shown in the foreground of the sketch. Here and there among the Heaths, creeping about in a perfectly natural-looking fashion, too, was the Gentian blue Gromwell, with some varieties of other hardy plants suited to the situation. Among these naturalised groups were the large Evening Primroses and *Alstroemeria aurea*, the whole being well relieved by bold bushes of flowering shrubs, so tastefully grouped and arranged as not to have the slightest trace of formality about them in any way. Such plants as these are not set out singly and without preparation, but carefully planted in beds of such naturally irregular outline that when the plants become established they seem native children of the soil as much as the Bracken and Heath around. It is remarkable how all this is done without in the least detracting from the most perfect order and keeping. Closely-shaven glades and wide Grass belts wind about among such objects as those we allude to, while all trees that require special care and attention show by their health and size that they find all they require in this beautiful

garden. It is more free from needless or offensive geometrical-twirling, barren expanse of gravelled surface, and all kinds of puerilities—old-fashioned and new-fangled—than any garden we have seen for years.

THE KITCHEN GARDEN.

CULTURE OF SPINACH.

ALTHOUGH Spinach is of easy culture some forethought is necessary in order to have it in good condition throughout the summer. As in the case of salading continuons regular sowings must be made, and a little neglect in this respect soon creates a serious gap in the supply. Frequent sowings and a deeply dug richly manured soil constitute the main elements of success in the culture of this wholesome esculent, and it is the non-observance of either one or the other of these important points, or perhaps of both, that accounts for the difficulty which many experience in maintaining a supply of tender juicy shoots during the summer months. Spinach is largely grown in Germany, where, owing to the severe winter, greens of all kinds are difficult to obtain early in the spring. It and Lettuces have to be relied upon for the first supplies, large breadths of them being sown early in the year, the Lettuces being cooked in much the same manner as the Spinach. It sometimes occurs in this country that a severe winter seriously cripples both the winter greens and those planted for spring use, in which case a few early sowings of Spinach would be found very acceptable. Occupiers of small gardens often commit the error of sowing too much at once. More is grown than can well be consumed when good, a great portion runs to seed, and just at the time when a picking would be very acceptable it is found that nothing but wiry stems and tough leaves remain. The same amount of seed, sown at frequent regular intervals, would furnish a continuons supply.

For the first sowing, which may be made towards the end of February, a warm and well drained spot should be chosen. The ground should be deeply stirred, incorporating with it some well rotted manure. Choose a fine day when the soil works free and mellow, and draw some broad shallow drills about 1 in. in depth and 1 ft. apart. It is well at this season to sow somewhat thickly, as owing to the coldness of the soil the seed does not always germinate freely, and vermin are apt to destroy a great portion of the seedlings as they appear above ground. If later on it is observed that the plants stand too thick, timely thinning must be practised. The ground should be well stocked, but good space is to be allowed between each plant; nothing is gained by crowding. Some good free light soil, such as the knocking out of pots with which some finely sifted cinder ashes have been mixed, will be found better for covering in the seed than the ordinary garden soil. The spring culture of Spinach does not present any great difficulties, the most cool atmosphere which more or less prevails during April and May, favours

View in the late Mr. Hewittson's garden at Weybridge.

its growth and allows it to become fully developed before it manifests any inclination to run to seed. When, however, the hot days of June and July arrive the case is different; then, unless high culture is practised, the plants will go to seed almost before they have furnished a picking.

For summer culture the ground should be at least bastard trenched, forking in some good rich manure. The seed should also be sown in drills, so that a flooding of sewage or manure water of some kind may be administered in hot weather. In order to obtain first-class Spinach in summer, the plants should never, from the time they are out of the seed-leaf, know the need of moisture at the root. A free, unchecked growth must be promoted and maintained. The leaves will then acquire that delicate flavour which is characteristic of, but which is too often found wanting in this vegetable. As I have before observed, frequent sowings are indispensable, and for a small household a pinch of seed sown every ten days or a fortnight would suffice to furnish a picking when needed. In order to ensure germination in dry weather, it is necessary to thoroughly soak the drills before sowing the seed. If the seed is then lightly covered and watered, and a sprinkling of dry earth spread over it, no further attention will, unless very exceptional weather prevails, be needed until the plants are fairly above ground. If these precautions are not taken, the seed is apt to lie dormant until a change in the weather takes place, a blank in the supply meanwhile occurring. I should add that a very open, sunny position should be selected for the summer culture, as, if grown in shady, over-sheltered situations, the growth made is of a weakly description, and the plants quickly run away to seed. For winter use choose a piece of well-drained and sheltered ground, and sow about the commencement of August, so that the plants have time to get strength before the cold weather arrives. Sow in the same manner as directed for the summer culture, and thin out to about 4 in. apart, which will allow of the plants spreading, and will better enable them to resist cold and wet than when growing thickly. Care must be taken to prevent the encroachment of weeds, the growth of which progresses at a rapid rate during the moist days of early autumn. A dressing of soot at this period would also be found beneficial. It is not a rampant, but a solid, compact growth that is most desirable at this time of the year, and soot and lime are the best manurial agents that can be employed for the purpose. They also serve to keep at bay the multitude of small snails and slugs which in the damp autumn days are apt to be so troublesome. The large-leaved Australian variety is very useful for summer culture. If planted in rich ground it grows very strongly, and furnishes a large amount of succulent, though, in comparison with the round-leaved kind, rather coarse leaves. This defect may be means of liberal culture be to a considerable extent removed.

J. CORNHILL, *Buffect.*

RAISING SEAKALE.

IN answer to "J. S. W.," allow me to say that a piece of fleshy root from 3 in. to 6 in. long must perforce have more strength and organisable matter in it than a seed; in fact, it is a plant in itself, lacking only the eyes or buds at the crown to start, and of these it long before contained the germ. I have no fault to find with raising Seakale from seed, as it is advisable to do so occasionally, especially where the roots have been subjected to hard forcing; but it is when pieces are planted from them after undergoing that process that they are weak and sluggish in moving. Perhaps these are the kinds of sets "J. S. W." has tried, and, if so, I do not wonder that he prefers seedlings; but if he will go deep and save the large pieces when digging up the crowns, and try them, I am sure he will at once see how superior they are. I well remember some thirty years ago reading Cuthill's book on "Market Gardening round London," and I think that was about the time when propagating Seakale by means of thongs first came into notice. If the plan had not answered better than seedlings it would not have been so generally adopted in place of the latter method. I have repeatedly tried the two side by side, and I could always get by far the best plants in winter when I used roots, and any one who has dug up a plantation knows how persistently the pieces left in the ground appear above it again and again. If it is the best way to get Seakale from seed, why not Horse-radish? as the habit of the two plants is precisely the same; but it may be objected that the one is grown for the sake of its crown, the other for the fleshy underground stem, and yet you cannot have the former large without the latter being in proportion to it. As regards the distance at which I plant Seakale, and about which "J. S. W." has commented, I may add that although I stated the plants to be 1 ft. apart, the rows are 2 ft. apart, which is quite far enough in ordinary soil to allow the leaves to have full spread. The way in which we manage this esculent here, and which I believe to be as good as any, is to have

plantations one under the other as it were, and to force them at two or three years old, which sets prepared ground at liberty for some other crops and affords a better rotation. In the winter the beds are covered with long stable manure or the straw from the icehouse, which is put on sufficiently thick to blanch the crowns of the Seakale as it grows, and when it is done with for this purpose it is in good condition for littering down Strawberries, to the beds of which it is removed as the Kale is cut. This is better than having to depend on one-year-old plants for forcing, whether grown from roots or seed, as, being so much stronger, the produce is always more satisfactory. S. D.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Late Peas.—In addition to late sowing, there are various ways of delaying the bearing of Peas, so as to convert what would otherwise be a glut into a regular and prolonged supply. It sometimes happens that after a period of cold chilly weather, which seems to keep everything at a standstill, there comes a hot burst of summer which brings such things as Peas all in together. If, in the case of Peas, this change could be anticipated, and the tops of a certain number of the late rows pinched off, the flowering would be delayed for two or three weeks, and if the Peas had not been sown too thickly, there would probably also be a more prolific crop, as many of the shoots so pinched will throw out several lateral shoots that will flower and pod freely during genial weather. The rows should be mulched on each side to keep the soil cool, as well as to keep in the moisture. If the pods are picked carefully from such kinds as Huntingdonian and others of the Champion of England section as soon as they are fit for use, a second crop of pods will follow in due course. I have often had a good late crop in this way from plants that had been allowed room enough to become strong, and so get a good grasp of the soil. If we have now, which is not improbable, a short spell of hot bright weather, Peas and other things will soon suffer from drought unless heavily mulched. This latter process, by keeping the roots cool, enables the plants to draw up a sufficiency of moisture to keep up the foliage of the plants, and prevent a too severe check being given.—E. HOBDAV.

The Best Manure for Turnips.—Judging by the report of the Aberdeenshire Agricultural Association, the question as to the best manure for Turnips seems to have been solved, as far, at least, as Aberdeenshire is concerned. Mr. Jamieson, the chemist to the Association, states definitely, as the result of experiments carried on systematically for three successive years, that the phosphates of lime decidedly increase the Turnip crop, and that cultivators need not trouble themselves to inquire whether the phosphates they employ are of animal or mineral origin. It seems also, from Mr. Jamieson's researches, that soluble phosphate is not so superior to insoluble phosphate as has been generally supposed. Nitrogenous manures have but little effect on Turnips when used alone, but when used in conjunction with insoluble phosphates they increase the crop. The fineness of division seems to assist the crop very materially, and the outcome of Mr. Jamieson's trials seems to be that the most economical manure for Turnips is probably insoluble phosphate of lime, from any source whatever, ground to an impalpable powder. The saving thus effected amounts to about one-third, that is to say, the quantity of manure necessary for an acre of Turnips will cost 20s. instead of 30s.—C. W. QUIN.

Winter Vegetables.—The extreme lateness of the season has a tendency to cause us to forget that the time has arrived for preparing for the winter and spring supply of vegetables and salads. In the case of many autumn crops, even greater care as to sowing at the right date is required than need be exercised with respect to the more important spring sowings, for then a few days one way or the other does not so materially matter. As many crops will be later than usual this year in being cleared off the ground, some disarrangement of the plan of cropping must necessarily ensue; but as Peas, Potatoes, &c., are cleared, late crops of Broccoli, Kale, Savoys, &c., should be planted forthwith. For the earliest Brussels Sprouts and autumn and winter Cauliflowers, it is always advisable to reserve some vacant ground, as if left in seed-beds until the crops are cleared it is too late, even in favourable seasons, to realise from them the full results of which they are capable. The most important sowings at present should consist of the different varieties of Cabbage, which should be now coming up (our earliest are getting forward for winter), and the latest should just be sown. Onions of the Giant Rocca or White Lisbon must be sown at once. Prickly or winter Spinach should also receive attention. We generally sow at two or three different dates, viz., the middle and end of August and early in September, as on some soils Spinach is a precarious but very useful crop. Cauliflowers require great care as to date of sowing; the

end of this month and early in September will be found early enough for mild districts. But for the supply of salading, a good breadth of various sorts of Endive, Cos and Cabbage Lettuces, and Chervil should be got in without delay, for although the summer was late in its arrival, the shortening daylight warns us that the sun's power is already on the decline.—J. Groom, *Linton*.

Sowing Late Turnips.—In many gardens these follow the early or second early potatoes; but of course, they may follow any other crop, or be sown wherever a vacancy occurs. An open situation suits them best, as they become more compact in growth and are better able to resist cold weather; I always think Turnips grow faster and better when exposed to full and free currents of air. If the land is in good condition, solid manures need not be used for the crop; and, if they follow potatoes, the working the land has received in digging them up will suffice beyond the surface culture always necessary to secure a fine tilth for covering the seed. It is best to sow in drills about $\frac{1}{2}$ in. deep and about 14 in. or 15 in. apart. If the land be dry, the drills should be well soaked with liquid manure previous to sowing. This will be of great advantage to the crop; its influence will be felt as soon as the young plants have begun independent action. A sprinkling of superphosphate along the drills when the seeds are sown will also be most useful if the land is not in good order; and even if the land be rich, a slight dressing of this manure is always of great value in an ungenial season, as it is in the early time of their existence that the fly or beetle is so destructive, and a stimulant pushes them on quickly out of the way of that pest. Hoeing, or stirring of the surface, should commence as soon as the young plants can be seen up in rows; and the rows or drills should have a hoe drawn through them, at the same time leaving the plants standing in little patches about 1 ft. apart. These patches will ultimately be thinned or singled out to one plant. Plants that will, under any circumstances, have to undergo some variation of temperature, should not be left too thick, as they draw each other up weakly, and are not so hardy, and the bulbs are not so good, as when each plant has space enough to form a good tuft or crown of foliage. The last week in July or the first week in August is a good time to sow, and the following are good hardy kinds to grow: Veitch's Red Globe, Orange Jelly, and Black Stone. The early White Stone may be sown in small quantities after the first week in August with a prospect of obtaining usable bulbs, as it turns in quickly. At the approach of cold weather in winter, some of the largest bulbs should be taken up and stored in the same way as Carrots or Beet, and they may have a ridge of soil drawn up on each side of the rows to protect them from severe frost.—E. H.

Laxton's Alpha Early Pea.—This is a first-rate Pea; sown a fortnight later than several reputed second early kinds it was fit to gather first. My experience of the very large-podded varieties is that they all take a long time to fill up after they look fit to gather. Generally speaking Peas are a good crop this year.—J. Groom, *Linton*.

The Potato Disease.—During the last week this has spread with alarming rapidity, and as the soil is saturated with moisture I fear we shall suffer heavily, as the crops are late and the tubers soft and immature. We have fortunately a change to finer weather at last, but even the increased warmth of the last few days appears to have favoured the development of the malady.—J. Groom, *Linton*.

—In this neighbourhood, (Huntingdonshire) which is a large Potato-growing district, the disease is already assuming alarming proportions. Even the Ashtop and other early kinds, which usually escape, are in some instances badly affected. The present agreeable change in the weather may perhaps check its ravages to some extent; but under any circumstances there must be a great loss of crop. I should strongly advise all who can to take up their Potatoes before they are badly affected, and plant the land with some crop calculated to be useful either in winter or spring. There is yet time to plant all kinds of winter Greens. As we shall probably have a genial growing autumn, Winter Spinach, Turnips, and Onions may also be sown, any or all of which will at least pay to grow as catch crops.—E. HOBDAV.

Botanic Gardens in Germany.—In Germany nearly every town has its Botanical Garden for furnishing means of instruction in that science; Berlin has two, the larger of which supplies 120 institutions of learning—including 100 common schools—requiring nearly 3,000,000 specimens. The plants are arranged in bundles and distributed in waggons. The flower described by the teacher is illustrated by a living specimen placed in the hand of each pupil. At Heidelberg a new and very handsome garden is being laid out, and in addition the forest trees in the castle yard are labelled with their Latin and German names, also the place whence they come—thus putting "tongues in trees" so that even the most careless observer may gain some useful information.—*New York Tribune*.

NOTES OF THE WEEK.

Zygopetalum Sedeni.—Of the numerous hybrid Orchids that have emanated from Messrs. Veitch's establishment at Chelsea, this certainly ranks amongst the most valuable as a decorative plant, as it flowers when there are comparatively few other kinds in bloom. It is the result of crossing the well known *Z. Mackayi* and *Z. maxillare*, and, whilst it has the free-flowering tendency and robust constitution of both its parents, it is much dwarfer in habit, being only about 12 in. or 15 in. high. The colour of the blossoms is a deep glossy purple, and the lip, which is broad, is of an intense rich purple, beautifully mottled with a lighter hue. It has been for some time in full beauty at the nursery in question.

Gentiana gelida.—In brightness of colour the flowers of this species rival those of the lovely spring Gentian (*G. verna*), and, owing to their being produced in clusters, their brilliancy is much enhanced. It is, moreover, more amenable to cultivation than its better known congener, which is an important point in its favour. It is one of the prettiest plants now in flower on the rockery at Kew, and also in the border collection.

Placards in Epping Forest.—We regret to see that the beautiful glades and nooks here are being defaced by a great number of placards—white boards with black lettering. If these are necessary, which we doubt, they need only be placed at the cross-roads and at important points here and there, and not in quiet parts of the forest within view of each other, as they are near High Beech.

Lasiandra macrantha floribunda.—This showy stove plant we saw finely in flower a few days ago at the Pine-apple Nursery. Its flowers, which measured fully 5 in. in diameter, are of an intense rich purple, and are produced in greater profusion than those of the type. It should therefore be grown in every good collection, as it well repays any extra care that may be bestowed upon it.

Cyananthus incanus.—This pretty Alpine plant is now flowering freely on the rockery at Kew. It differs from the only other introduced kind in having a less vigorous growth and smaller flowers. It has slender, creeping branches furnished with small hairy leaves, and terminated by a solitary flower of a soft, purplish-blue tint. It is perfectly hardy at Kew. It is a native of high elevations in the Himalayas, from whence it has been recently introduced in quantity.

Monarda Bradburyana.—This handsome North American perennial does not appear to be grown much, although it is quite as pretty as the other kinds and very distinct. The flowers on plants of it at Kew are yet in too undeveloped a state to show their true character. Plants of it raised from seed sown last autumn are now about 2 ft. high, and have leaves similar to those of *M. fistulosa*. The flower-heads are arranged in whorls, and the blossoms have long, hanging, three-cleft lips. The colour is rosy-lilac, copiously spotted with deep purple.

Echinacea purpurea.—We have received from Mr. Stevens's garden at Byfleet some remarkably fine examples of this handsome hardy perennial. Its flower-stems, which rise from 3 ft. to 4 ft. high, are terminated by flower-heads, the central florets of which are of a dark brown colour, and form a close, conical boss, on which the golden anthers are shown off to advantage, while the long pendulous straps belonging to the ray florets hang down in the form of a long purplish-pink fringe, thus giving the plant a singular appearance. In order to grow it well, it requires a rich, deep soil in the warmest spots of the garden. It is a native of the Southern and Western United States of America.

Vanda insignis.—In directing attention to this Orchid it is well to state that two plants bear this name, one of which is merely a fine variety of *V. tricolor*. The true plant to which this note refers is a very fine species and somewhat rare in collections. In habit it is similar to *V. suavis* or *V. insignis*. The flowers, however, are very distinct, being of a different form and having a broad open lip of a rich mauve tint surmounted by a pure white crest; the sepals are broad and slightly incurved and deep chocolate in colour, marbled with greenish-yellow. It was in perfection a day or two ago in Messrs. Veitch's nursery at Chelsea.

Ixia and Sparaxis at Tooting.—These charming plants are now making a fine display in Mr. Barr's grounds at Tooting, where they are growing in frames from which the lights have been removed for a considerable time. They contain chiefly varieties of *Ixia* and *Sparaxis*, the flowers of which represent almost every conceivable shade of colour, including the peculiar sea-green tint of *Ixia viridiflora*, with its black centre. It is much to be regretted that these charming plants have of late years fallen into disfavour, for few flowers are better adapted for decorative purposes, and even in a cut state they last a long time in perfection.

Batatas paniculata.—In the Victoria Lily house at Kew this fine trailing plant now forms an attractive object. Its slender branches spring annually from a fleshy stem, and attain many yards in length in the course of the season; its leaves are similar to those of the common Blue Passion-flower, and its flowers resemble in form those of the common *Convolvulus*, but they are considerably larger and of a deep purplish-violet colour. They are produced in clusters, and though each flower lasts but a day its place is taken up by others in succession. It is a very desirable plant, even for small houses, as it does not require much space, neither does it need that excessive heat which some stove subjects do.

Milla longipes.—The brief description given of this new bulbous plant (p. 81) was taken from a cut specimen of it, which was shown by Mr. Elwes at South Kensington. Since then we have seen it growing in masses at Mr. Ware's at Tottenham, in Mr. Barr's grounds at Tooting, and also at Kew, and are now better able to speak of its merits. When seen in quantity in bright sunshine with its starry, white blossoms fully open, it has a pretty appearance, and then the livid purple on the outside of the petals is not seen, which detracts so much from its beauty. The large umbels of slender-stalked flowers, too, are very graceful, and admirably adapted for use in a cut state, a condition in which they last a considerable time in perfection. As it may be freely raised from seeds, and the seedlings flower the second year, no doubt it will soon become widely distributed.

Specimen Fuchsias in Six Months.—One of the finest examples of culture in the way of Fuchsias which we have ever seen we saw the other day in Messrs. Henderson's nursery at Pine-apple Place. The plants, which are now in 6-in. pots, are the produce of cuttings struck in February last, potted on in good loamy soil, and subjected to the treatment which Fuchsias generally receive, except that they have had a dressing of Clay's Manure, which is stated to be very efficacious in stimulating the growth of plants in pots, especially such as are soft-wooded. The Fuchsias in question are 3 ft. high and as much through, remarkably strong and gracefully branching, and last, but not least, loaded with blossoms.—S.

The Late Thunderstorm.—We learn from various sources that the unusually severe storm on Saturday night last did much damage to glass structures, especially at Twickenham and its neighbourhood. At Kew the houses were much shattered by the hail; indeed it is estimated that as many as 25,000 panes of glass have been broken. The occupiers of small gardens for trade purposes, which abound in the adjoining districts, have also suffered heavy losses through glass breakage, and we hear that subscriptions are being raised to aid in repairing the damage.

The number of persons who paid for admission to the Royal Horticultural Society's gardens, South Kensington, on Bank Holiday, August 4, was 11,342 at 2d., = £94 10s. 4d.

Rose Celeste.—This old-fashioned Rose is blooming well with me this year notwithstanding the unfavourable weather we have had. It is rosy pink in colour, and perhaps the most beautiful of all Roses in the bud state.—T. WILLIAMS, *Ormskirk*.

Hampton Court Gardens upon an August Bank Holiday afford one of the most pleasing sights to be seen in a country where so many thousands of people are perforce debarred by their vocation and place of residence from often enjoying the pleasures incidental to a rural or garden life. Tens of thousands of persons, of all ages and classes, the majority unmistakably of the true town type, wander about the broad walks and over the green sward, enjoying the trees and flowers in a way that shows how all pervading is the love of all that is sweet and beautiful in Nature. Hampton Court Gardens are peculiarly rich in trees, and not the least interesting feature is the lines of naturally-grown Yew trees, under the shade of which tired people love to rest. How thankful should the present generation be that these trees were spared from the Dutch shears of olden days. The green sward is in luxuriant condition, and not injured in the least, although thousands of visitors walk over it as they please. In respect of freedom from restraint, Hampton Court Gardens are far before Kew. The bedding plants are, of course, just now a certain source of attraction, though in poor condition as regards bloom. From uninteresting seroll and carpet beds—containing the customary Golden Feather, *Alternanthera*, *Mentha*, *Echeveria*, and a few other plants repeated again and again—one turns with a feeling of relief to the masses of *Lilium candidum*, the charming effects produced by the elegant *Lathyrus grandiflorus* as it runs over dwarf shrubs, and similar combinations. If the whole system of flower-beds were swept away, and the borders filled with grand collections of hardy plants, the gardens would gain greatly by the change.—A. D.

PLATE CXCII.

A GROUP OF NEW CLEMATISES.

Drawn by CONSTANCE PIERREFONT.

From the time when Messrs. Jackman & Son, of Woking, gave to English gardens *Clematis Jackmani* and *C. rubro-violacea*, raised in 1862, down to the present, a constant succession of new varieties has been kept up. Almost every year new forms bearing flowers large in size, perfect in outline, and striking in colour are produced. Clematises are divided into several divisions. Probably they are capable of being grouped into two sections—winter and spring bloomers and summer and autumn bloomers. There is a very great difference between these two, and just because that fact was not sufficiently understood, some who have attempted to cultivate them have failed. Strong-growing types like the well-known *C. Jackmani*, *C. rubella*, *C. magnifica*, and others flower from the growth put forth during the spring and summer, and need to be pruned back rather severely in winter, else there is a natural tendency for the plants to flower farther and farther away from the base as the strongest shoots are put forth from the tips of the old wood of the previous year. What is known as the *C. lanuginosa* type, under which heading are included many very fine and beautiful varieties of great decorative value, flower on short lateral summer shoots, which are not of such a gross character as those of *C. Jackmani* and others, and do not require such hard pruning. The cultivator in training these plants must have regard to the accommodation of the house, wall, or trellis on which he wishes to operate, and the nearer to the ground that he requires to have flowers the greater the necessity for pruning close. The other section is known as the *C. patens* type, *C. patens* being also known in gardens as *C. azurea grandiflora*. Under this heading we get quite a large group of beautiful, free-flowering varieties that produce their flowers much earlier than the varieties of the *C. Jackmani* type, because they flower from buds formed on the old or ripened wood; therefore to cut back the old wood in the case of the varieties of the *C. patens* group as one would that of the *C. Jackmani* type would be to risk the crop of flowers in the following spring. The long shoots that are put forth this summer should be preserved, and the old decayed wood which furnished flowers in May and June only cut away. Some nurserymen mix up these Clematises in their catalogues in a rather haphazard fashion, and purchasers buy without being made aware of the distinction between spring bloomers and summer bloomers, and therefore fail in many instances to get flowers.

The three fine varieties represented in the annexed illustration were raised by Messrs. Jackman & Son, of Woking. Fair Rosamond and Mrs. G. Jackman belong to the *patens* or spring-flowering section; the former has well-formed, blush-white flowers, having indistinct wine-red bars to each petal; the latter is a quite new variety, having large pure white eight-petalled flowers, and pale straw-coloured stamens. They are admirable varieties for pot culture. Robert Hanbury belongs to the *C. lanuginosa* section, and is remarkable for its bold, flat, well-formed flowers, and its soft satiny tint of colouring, which gives the blossoms a peculiarly refined appearance; the colour is a bluish-lilac, flushed at the edges with red, and having the bar slightly tinted with red. It is a comparatively new variety.

The Clematis has been described as a "gross feeder," and in all its stages and modes of growth a deep, rich soil is indispensable. The stock on which the Clematis is grafted is a vigorous grower, and puts forth a large mass of thick, fleshy roots, which not only need to be well sustained by means of rich soil, but also by an abundance of water in dry weather. In spring and summer good mulchings with strong manure should be given, and when the plants approach full bloom, occasional soakings with liquid manure, or dressings of some good patent manure, should also be given. In autumn some rich manure should be forked in about the roots, and some scattered on the surface about the plants, to be washed into the soil by means of the autumn and winter rains.

One very excellent mode of cultivating the Clematis in pots, to flower in May and June. Those who have seen the beautifully grown and flowered specimens which Messrs. Jackman and others are in the habit of showing at the horticultural exhibitions held in London in May and June, cannot fail to have been struck with the adaptability of the Clematis as a pot plant. The spring-flowering sorts are most suitable for this purpose. In the pages of "The Clematis as a Garden Flower" it is recommended that the plants be grown in 10-in. or 12-in. pots, in a rich, loamy soil. In pots of this size the plants should cover sufficiently cylindrical trellises of about 2 ft. high, and 1 ft. 6 in. across. They flower from the well-ripened wood of the previous year's formation, and hence a supply of this wood must be kept up annually. By encouraging a free growth after the flowering season is past, these plants can be forced into bloom by

A GROUP OF NEW CLEMATIS.

placing them in a genial warmth when growth sets in, and they may also be retarded by subjecting them to cold treatment. They should be repotted annually in a rich soil.

Well-established plants in the open air will, if carefully attended to, cover a great space. The budding shoots need to be carefully trained and tied in, placing them as widely apart as possible, as successive shoots and lateral ones will fill up the intervening spaces. If the shoots be not trained in this way they become matted together and are driven in one direction by the wind. There is another great advantage in training them as directed—the larger the space filled by the shoots the better do the plants display their heads of bloom.

A selection of a few leading varieties should include the following of the spring-flowering type:—Albert Victor, Lady Londesborough, Lord Londesborough, Miss Bateman, patens, Sir Garnet Wolseley, Standishi, Stella, The Queen, and Vesta. Those who are fond of double varieties—and they are of great value as conservatory plants for training against pillars and trellises—will find Countess of Lovelace, Fortune, John Gould Veitch, and Louise Lemoine well worthy of culture. Of the Lauginosa type, Aureliana, Gem, Henryi, lauginosa nivea, Marie Lefebvre, Morikata Oke, Otto Frobelt, Symeiana, and William Kennett should be selected; these are perhaps of a rather more tender character than any others, and should therefore have, when planted out-of-doors, open, warm situations, and a well-drained subsoil. Of the grand summer-blooming varieties, some of the most useful will be found to be Alexandra, Jackmani, Lady Bovill, Mrs. James Bateman, Prince of Wales, Rubella, Star of India, Thomas Moore, Tunbridgeensis, Viticella rubra grandiflora (small-flowered, but very distinct and attractive in colour), and Velutina purpurea.

R. D.

GARDENING FOR THE WEEK.

Flower Garden.

Auriculas.—At this season, when all re-potting must be completed as speedily as possible, to those intending to add to their stock either by purchase or exchange, a few words on packing may be useful. The best way is to pack the pots in which the plants are growing in a round basket in an upright position, and hold them in their places by strong twine laced across the basket. Stout sticks should then be inserted in the rim of the basket, and tied firmly together at the top, and over the sticks a mat should be tightly sewn. I have received plants from amateurs badly packed, and I have heard others make the same complaint. In the case of those who have but little experience, the best way to pack is to turn the plants out of their pots, reduce the balls of earth very considerably, and wrap them round with a piece of paper, tying all firmly with matting. The plants can then be packed closely together in dry hay or Moss. There is no danger of any injury if they are packed rather firmly, but if packed loosely, the chances are that many will be injured in transit.

Carnations and Picotees.—The information which I have been able to glean as to the condition of these plants is somewhat unfavourable. One grower from the northern district of Yorkshire writes to say that he will have a number of flowers in by the 12th of August on plants that have been forced under glass, but that his general collection will not be in bloom until September, and finally that he will not be able to put down so many layers as he did last year by 1000. This I can quite believe, as my own collection, under more favourable circumstances, is nearly as much behind. Notwithstanding that the special exhibition of these plants has been delayed for three weeks, the flowers will not be at their best by the 12th of August. Some fancy that growers who have the convenience of forcing houses obtain a considerable advantage over those who have no such accommodation; but I never use artificial heat to get the flowers in in time. It was tried for one day only this year, but I was afraid the blooms produced would be out of character, and so gave up the experiment. If they are placed in a greenhouse, the lights may be kept closer than usual, but I never, even on cold nights, shut the house up entirely. Pay attention to watering as the plants seem to require it.

Hollyhocks.—Where these stately plants have made good growth, they will speedily repay the cultivator for any pains which he may have taken to bring them up to the highest standard. It is some years since we saw an exhibition of Hollyhocks in London, but let us hope that some means may be adopted to have one of these, together with Dahlias, Gladioli, and other autumn flowers. A good exhibition of Roses can usually be had in September; Verbenas, too, come in then and create variety, and so do Phloxes, Pentstemons, and other cut hardy herbaceous flowers. Attention must still be paid to stopping the side growths and to putting in such eyes as have leaf buds.

Pinks.—Beds of these are still gay even now, which is six weeks after their usual time of flowering. There is very little increase from side growths this year, and therefore it will be necessary for us to save all our old plants. Sometimes these do quite as well as pipings, so far as a good display is concerned; but they would not yield such large flowers for purposes of exhibition, although the lacing from old plants is generally good. Seedlings should be pricked out into good soil, and be encouraged to make good growth, so that they may be planted out into their blooming quarters next month.

Pansies.—These are still producing good blooms, and it will soon be necessary to put in cuttings of them. Indeed, it is quite time they were put in if it is intended that the plants are to flower early in pots. The easiest way is to take the very smallest growths that come up from the base of the plants; thick, succulent growths, with hollow stems, are useless for cuttings. Pansies strike best under handlights in a shady place, in a compost of equal parts leaf-mould, fine loam, and sharp sand; keep the lights rather close and shade from the sun until roots are formed. If there is any green fly on the growths dip them in soapy water before inserting them.—J. DOUGLAS.

Stove.

Celosias are amongst the most useful annual decorative plants grown, and at no season do they come in so serviceable as through the late autumn months; the latest sowings will now have made some progress, and attention must be paid as to having sufficient pot-room, as they, in common with all quick-growing plants, if allowed to remain, even for a short time, deficient in this respect, can never afterwards be set to rights. They are naturally disposed to grow higher than often required, to counteract which they should from the first be kept as near the light as they will admit of. Use the syringe regularly to the undersides of the leaves to keep down red spider, to which they are subject.

Table Plants.—Where these are required, there needs to be a continuous supply of young stock coming on, or they soon get too large, and when so used they are very objectionable. Tastes differ somewhat as to the different plants used, but it is generally admitted that the spare-growing, lightest, most elegant plants are the most suitable, amongst which we may be reckoned some of the Palms, of which *Chamedorea graminifolia*, *Cocos Weddelliana*, *C. plumosa*, and *Geonoma gracilis* are the best; add to these, *Aralia Veitchi*, *reticulata*, and *gracillima*; *Croton angustifolium*, confined to a single shoot; the narrow-leaved *Dracenas*, such as *nigro-rubra*, and several of the hybrids of a like character; *Pandanus elegantissimus*, *P. Veitchi*, and the variegated *P. javanicus*; *Cyperus alternifolius* and its variegated form; *Jacaranda mimosaefolia*; *Reidia glaucescens*; and *Terminalia elegans*. These, and anything else employed for a like purpose, should in all cases be confined to a single stem; anything approaching a bushy habit renders them too heavy, and unfit for use. Such plants of the above as can be increased from cuttings, when they get too large, may be cut back, and after the shoots have broken and attained a considerable size, taken off and struck. Palms can be raised from seed or procured so as to keep up a supply from those who grow them for the purpose. With plants to be used in this way another matter of importance is never to get them in too large pots; 6 in. diameter is quite as big as admissible, or necessary, for, with the aid of a little manure water, they can be grown to a size even larger than adapted for the purpose, still retaining all their lower leaves fresh and healthy.

Orchids.

Except as regards the coldest division of Orchids it will have been necessary all along this season to use more fire-heat than usual, and should the weather continue of the same cold unseasonable character through the remaining portion of summer, it will be requisite to still further keep on with a considerable amount of artificial warmth, for without its means not only will the night temperature of even the intermediate or Cattleya house be too low, but the day heat as well, should cloudy weather and cool air, like we have hitherto experienced, continue. This is a matter requiring particular attention, as though growth in these plants can be kept on with fire-heat late in the season, yet it is anything but desirable that they should—with such exception as the naturally latest bloomers—not have completed their growth before the late short autumn days are upon us. Were it not that to save a little labour and a little extra expense, some growers resort to fixed shadings or the glass smeared with some composition it would be scarcely necessary to point out the more than usual mischief caused on a season like the present by these methods of excluding the sun, where up to this time we have not on the average had more than one day's collective sunshine in each week.

Cattleyas and Lælias.—These now, when their young roots have got well hold of the soil and attained more solidity, will bear

a little more water than earlier in the season. It is well to caution beginners that it is much better to err on the score of keeping them a little too dry than too wet at the root; and with the absence that we have so far had of the sun's drying influence, it is well to use some less atmospheric moisture, unless comparatively more air is admitted, with additional fire-heat to allow of this without the temperature getting too low. Late spring-blooming Cattleyas, such as the *Aclandia* section, the different forms of *C. guttata* and *bicolor*, with the still later *C. intermedia* forms, of which *C. Harrisoni* or *violacea* may be looked upon as the latest, should have their growth pushed on as soon as the flowering is over. May I here say a word in favour of some of these fine old species, which, in the rage after new fashionable Orchids, are by many neglected, and things of a far less decorative value or general usefulness grown in their stead. I have seen some of the different forms of *C. intermedia*, when well managed, with the large size they will attain and profusion of flowers they bear, as also the length of time they will last, amongst the most serviceable and effective plants in the whole family of Orchids, and for cutting purposes they are far more suitable than the larger flowered kinds; the darkest form generally known under the name of *C. violacea*; if the flowers are cut whilst young, will last in water for three weeks.

Miltonias again may with truth be classed amongst neglected Orchids that are really worth cultivating. The different forms of *M. spectabilis*, growing as they do to a considerable size in little time, and producing proportionately large beautiful coloured flowers, that last either on the plant or in a cut state for a long time, in addition to their habit of blooming late in the summer, when comparatively few Orchids are in, render them of especial value. One objection raised against this, the thin-leaved section of *Miltonias*, is that they often have a yellow appearance in their leaves, from their inability to bear a full complement of light, much less sun; but I have always found them to keep their colour much better when placed near where the air is admitted, with the addition of large sheets of tissue paper laid on the plants during the day when the weather was bright. With these and a few others that will not bear as much sun as the general stock, I have found this much better than over-heavily shading the whole. *M. Moreliana*, the best form of which has no equal in its respective colour amongst Orchids, should be in even the most select collections; it requires treatment in every way like the others.

Anguloas and Lycastes.—*A. Ruekeri*, *A. Clowesi*, *A. eburnea*, and *A. virginalis* do much the best with an intermediate temperature at the coolest end of the house, their pseudobulbs under such conditions attaining a larger size, and the plants being able to produce a proportionately greater number of flowers than when grown warmer. They will now be in the full season of their growth, and should be moderately supplied with water at the roots. The same applies to *Lycastes*, of which *L. Skinneri*, in its many distinct and beautiful varieties, is one of the best long-flowering plants grown.

Oncidiums.—The different species of these that succeed in an intermediate house, such as the varieties of *O. barbatum*, *O. Barkeri*, the many forms of *O. crispum*, *O. sarcoodes*, *O. Papilio*, and the majority of others that do well with similar treatment, will now also be in the height of their growth. Most of these plants have stout leaves, and will bear more exposure to full light than some things, and I have always found the best position that could be afforded them in the house, resulted in the largest bulbs and greatest amount of bloom. Most *Oncids* will bear when growing more water at the roots than the soft tender-rooted kinds.

Cool Orchids.—The family of *Odontoglossums* and *Masdevallias* are the representatives most worthy of especial consideration in the matter of temperature, but unless where there are a number of houses devoted to Orchids, so as to accommodate those that require different treatment in this respect, it becomes a necessity to grow a good many other kinds with them, some of which are benefited by a few degrees more heat than the plants named like; yet no harm will be done in a compromise of this sort, provided treatment is given that will compensate for this. *Masdevallias* and *Odontoglossums* in common with other Orchids will not suffer through being subjected to a little more heat than they absolutely need, if accompanying it they are grown nearer the glass with a little extra air, as a matter of course using somewhat more atmospheric moisture when the weather is hot and the external air admitted is comparatively dry.

Epidendrum vitellinum and *Mesospinidium vulcanicum* are two of the most desirable and distinct-coloured Orchids grown. Both do much better in the cool division than when kept warmer. If placed at the warmest end of the *Odontoglossum* house they will be found to not only thrive but flower profusely. When these plants are grown in sufficient numbers so as to admit, when in bloom, of being dispersed about amongst the *Odontoglossums* and *Masdevallias*, an effect of colour is produced which is not

equalled by a combination of any other flowering plants that I recollect.

East Indian House.—There will be comparatively few plants in bloom here, but amongst those that will flower from this time through the autumn will be *Aerides suavisimum*, the fine and scarce *A. quinquevulnerum*, with a few *Vandas* of the tricolor and *suavis* section, and *V. cœrulea* later on, as well as other species that from time to time push their flowers later than the usual season. A little care will be required in the use of the syringe, to see that advancing spikes of the above do not get too wet.

Cypripediums.—Most of these that require considerable heat will now be in full growth, including the different forms of *C. caudatum*, *C. hirsutissimum*, *C. laevigatum*, *C. Lowi*, *C. Stonei*, with other kindred species, and the hybrid sorts that need a like temperature. These plants also do better with more light than they often get; their foliage collectively is little susceptible of injury from a moderate amount of sun, and though under such a course of treatment the leaves do not usually get quite so large or long as when more darkened, yet the general condition, and the amount of flower which they will produce, will be more satisfactory. They like plenty of water when growing, and will bear it applying freely when managed as here advised.

Insects.—The maximum temperature at this time required invariably brings with it an increase in insect pests, which will now be troublesome, more or less, as the collection is comparatively clean or otherwise, and in no department of gardening is a thoroughly cleanly course of management, such as is calculated to keep the different insects that prey upon the plants down to the lowest possible point, more conducive to a real economy of labour; where, on the other hand, scale and the most injurious little yellow thrips are not got well under, they cause a never-ending tax on the labour, the plants not thriving as they ought. Far better only grow half the number, if there is not enough time to keep the whole in a satisfactory state as regards this most important as well as labour-absorbing part of the care they need. Respecting scale, its extermination is simply a matter of time and perseverance, as by sufficient attention it may be altogether got rid of. Where yellow thrips exist in quantity, especially among thin-leaved Orchids, such as the greater portion of *Odontoglossums*, it requires time and a determination to get them under, otherwise they do irreparable harm to the young, unfolding leaves, particularly at this season. Species like *O. vexillarium* are most injured by it. Continued sponging and washing are requisite, for this insect is difficult to kill with Tobacco smoke, and this section of Orchids have a great dislike to it.

Ferns.

Where there is a house devoted to these plants, or where they have to be grown along with others, there should always be provision made for keeping up a sufficient number of the kinds most useful for decorative purposes in a small state, by annually potting off a number of the seedlings of those that usually come up from self-sown spores, and by sowing the spores of such others alike suitable for use in this way as need to be so raised. The different forms of *Pteris serrulata*, both crested and plain leaved, are amongst the most hardy and useful plants that can be grown for standing about in greenhouses, intermediate houses, stoves, conservatories, or rooms. So accommodating are they that they will succeed almost anywhere. *Adiantum euneatum* is also one of the best, doing well with either a medium amount of heat or in a cool house, and lasting in a presentably fresh condition for some months in ordinary living rooms. *A. formosum* and *A. hispidum* will both succeed for a like purpose. *Davallia bullata*, *D. Nova-Zelandiæ*, *D. canariensis*, *Nephrolepis exaltata*, and *Pteris cretica* are all extremely useful for using either amongst flowering plants or in any place where elegant green-leaved subjects are wanted. There are but few private places where the stock of the above might not with advantage be increased. All can be raised from spores or by division. The *Davallias* can be propagated by division of the rhizomes when the plants are at rest. I may here observe that all these, as well as other Ferns, can be kept in a vigorous healthy state in very small pots, provided they are regularly supplied through the growing season with weak manure water; by the use of this, even when the roots are so confined that the growth would otherwise be both weak and yellow in colour, the fronds will come sufficiently strong, possessing the desirable deep shade of green. The hardy *Scolopendriums* are excellent plants for employing in like manner, and their distinct foliage is an advantage. Such species as *Lomaria gibba* and *L. cycadiaefolia* should be annually raised from spores, as they are most serviceable in a comparatively small state. To be successful with the latter variety the fertile fronds should be taken from the plant as soon as ever there is an indication in the coverings of the spore-vessels to rise, otherwise the spores will fall and be lost. The fertile fronds should be broken up into small pieces and scattered over pots or pans filled

with a mixture of peat, grit-stone, charcoal, or crocks, with a liberal addition of sand, kept moist, and a sheet of glass laid on the top, placed away from the sun in a little warmth, where they will soon vegetate. Ferns, such as most of the Tree species, that are inclined to get too large in the head for the places they occupy, may, now that their summer crop of young fronds is fully developed, have a considerable number of the old ones cut away. They will also bear washing with Tobacco water to destroy thrips. Should these exist, this is the most effectual method of killing both these insects and their eggs. Where there is scale on Ferns, if it is not kept in check, it becomes an intolerable nuisance, as it spreads with great rapidity to all that stand in contact with, or are overhung by, such as are affected with it.

T. BAINES.

Indoor Fruit.

Pines.—Smooth Cayennes, Charlotte Rothschild, and other winter-fruited Pines that have done flowering, should now be encouraged to make free growth by means of frequent supplies of manure water. If the pots are not plunged too deeply the soil will dry more quickly, and thereby permit fresh stimulants to be administered more frequently than would otherwise be the case, without danger of the soil getting soddened. Still ventilate freely, but shut up early, enclosing plenty of atmospheric humidity. Syringe the plants overhead on the hottest days, but at other times damp the beds, pots, and wall surfaces only. Any not out of flower must be carefully guarded from moisture lodging on the blossoms. Similar treatment must be given to Queens that are intended to show fruit from the new year onwards, and which ought to have completed their growth by, at the latest, the middle of September, when they should be kept drier, both as regards moisture at top and bottom, and a minimum amount of heat, compatible with the maintenance of vigorous health, should also be maintained. Ripening fruit must have plenty of air, and though it is desirable that the soil should now be somewhat drier than for plants in free growth, it should never be allowed to get quite dry, for it is a mistake to suppose that Pines can be roasted into flavour. A notion is prevalent that entirely withholding water from the first indication of colouring improves the flavour; but such is by no means the case, rather the reverse, as those who are sceptical as to this matter may soon learn by making a trial of the two plans. Keep succession stock in free growth for the present, and if a general cleansing and overhauling of the pits and houses has not yet been done, advantage should be taken of fine weather for performing these operations.

Vines.—It will still be necessary to carefully guard against scalding late Grapes that have not yet passed that critical juncture. Give fire-heat at night, and keep the ventilators an inch or two open in order to prevent condensation of moisture, and this, coupled with free day ventilation, will be found to be a sure preventive of the disease. Houses containing ripe fruit should be kept as cool as possible, and if the weather be sunny a slight shade would tend to preserve the colour of the fruit for a longer period. Check any disposition which early Vines may still show towards making fresh growth by persistent pinching, and see to the renovation of the borders as early as circumstances will permit, in order that the roots may get established in the new soil before the close of the growing season. Pot Vines that have completed their growth may be afforded more liberal supplies of air than hitherto, and the fullest exposure to light, but there must be no withholding of water at the roots under the delusion that it tends to assist maturity; in one respect it does, but it is premature maturity, and necessarily hinders the full development of the buds.

Peaches and Nectarines.—Trees from which the crop has been gathered should be regularly syringed, in order to maintain cleanliness of foliage, and if fly be troublesome fumigate with Tobacco paper. Do not hesitate to cut away any straggling shoots that are likely to prove injurious through overlapping others, and which hinder the full action of light and air on the fruiting wood of next season. Keep inside borders well supplied with water, and the trees that are swelling off fruit should have manure water. Soil should be got in readiness for making new borders or renovating old ones, as transplanting and top-dressing should be done as soon as ever there are indications of maturity of growth by the falling of the leaf; there is then no perceptible check as regards fruiting the following season.

Strawberries.—All should ere this be in their fruiting pots, and be growing rapidly. Keep the runners constantly pinched off and never allow them to suffer even slightly in the matter of watering or to become drawn and weakly from standing too closely together. They should be kept free from weeds by pulling them out as soon as perceived, as under no circumstances should the surface soil be broken up; such a proceeding should ever be looked upon as wanton destruction of the best roots of the plants. If, as was recommended in a former calendar, a small proportion of bone manure

was incorporated with the soil for potting, no manure water will be required, as the aim should be the obtaining of sturdy, fruitful crowns rather than an immense profusion of leaves, accompanied as they would be with large sappy crowns difficult to ripen.—W. W.

Kitchen Garden.

When a choice of two evils occurs, it is obviously the best policy to select that which appears to be the less of the two; and, as the Potato murrain has now set in, by far the lesser evil will be to at once dig up all kinds that are anything like full sized: even though some may go bad afterwards, it will be better than leaving them in the ground to be entirely destroyed, as must inevitably be the case this extraordinary season. Whatever may be the predisposing cause of this scourge, it is certain that thundery weather favours its development, for since the severe tempest that occurred on the evening of the 1st and morning of the 2nd inst., the haulm of many kinds has died off alarmingly quick. When the Potatoes are harvested, there will be ample space for all kinds of winter Greens. The planting of Savoys, Kales, Coleworts, and late Broccoli should be completed forthwith, and earlier plantations will now be fit to earth up, a practice at once beneficial both as a protection against wind-waving and as a means of aerating the soil. A last sowing of Cabbage and Cauliflower may now be made on a warm sheltered aspect to stand the winter. These will make good plants for putting out in spring to succeed the late autumn plantings, the produce of seed sown a fortnight or so ago. The sowing of Winter Spinach should not be longer delayed; a deep, moderately rich soil, and a dry situation suit it best, and the plants should not be nearer together than 1 ft. each way. We prefer the rows 2 ft. apart, in order that the ground may be the more conveniently hoed and the produce gathered. Onions of the Tripoli and Giant Rocca kinds should at once be sown rather thickly in drills, to be planted out early in the new year. Of course this plan is practised with a view to the utilisation of ground, there being no valid reason against sowing them sufficiently thin, and where they are to mature, except the question of space, which in most gardens is now fully occupied with winter and late maturing autumn crops; such concentration of space is therefore necessary. Winter Lettuces (Bath Cos) Endive, and Turnips, should all now be sown in quantities more or less according to circumstances. Lettuce and Endive may still be planted out with fair prospects of success. If, as often happens, ground for Celery could not be had in sufficient quantity at the proper time, any planted now will come in admirably for soups, and will save the general stock. It should be planted out thickly, and, like Lettuces, that is all the culture which it will require seeing that it is intended for soups only. Earth up the earliest planted Celery; mulch and stake late Peas; cut Globe Artichokes as soon as they are fit for use—even if not required they had better be cut, and when done bearing, all the old stems should be removed and the ground loosened with forks or hoes. Remove also the seed stems from Seakale, and thin out the crowns if crowded, in order to favour early ripening. Tomatoes are late, but with a continuation of the present favourable weather, they will yet fruit abundantly, and should be encouraged by constantly pinching and training out the shoots, aiming rather at early maturity of a little fruit, than a quantity which perhaps may fail to ripen at a later period.—W. W.

Extracts from my Diary—August 11 to 16.

FLOWERS.—Putting in cuttings of *Alyssum variegatum* for stock. Staking and tying *Chrysanthemums*. Putting in cuttings of *Verbena*s for stock. Stopping *Carnations* in pits. Re-arranging plant houses. Propagating *Pelargoniums* in boxes. Placing *Chrysanthemums* in a sunny position. Putting *Primulas* into their flowering pots out of 3-in. ones.

FRUIT.—Nailing Vines to walls outside. Brushing off Peach leaves in earliest house, in order to ensure the ripening of the wood. Going over Grapes and taking out all shanked berries. Gathering all ripe Apricots. Trenching ground for Strawberries. Netting Plums, in order to preserve them from birds. Planting out bed of Strawberries. Gathering Juneating Apples for dessert. Pruning shoots of Pears on walls. Potting Strawberries for forcing, and layering a few more for planting out.

VEGETABLES.—Sowing Turnips for autumn use between Gooseberries. Sowing Bath Cos Lettuces and Enfield Market Cabbages. Planting Cattell's Eclipse Broccoli. Sowing more Little Pixie, Carter's Early Heartwell, and Daniel's Defiance Cabbages; also Flat Italian and New Giant Rocca Onions. Tying and stopping Cucumbers. Sowing Incomparable and All Heart Cabbages. Thinning out Parsley and Lettuces. Sowing Mustard and Cress; also Hammer-smith Hardy Green and Wyatt's Green Curled Lettuces, and Chou de Milan Cabbages for succession. Pulling up Broad Beans and hoeing and cleaning the ground ready for next crop. Tying and stopping Tomatoes in houses. Sowing winter Cucumbers (Telegraph, Hedsor Prolific, and a cross between Montrose and Lord Kenyon's

Freebearer). Planting Snow's Winter White Broccoli after Potatoes. Digging ground for winter Spinach. Planting ground after Broad Beans with Garnishing Kale and Little Pixie Savoys. Gathering all Scarlet Runners ready for use. Hoeing ground between last-planted Cabbages. Removing superfluous wood from Tomatoes on outside walls.—R. G., *Burghley*.

PROPAGATING.

White Lapagerias.—Last year I stated that in order to secure strong growths annually and plenty of flowers, it would probably be found the best plan to propagate Lapagerias as pot Vines are increased, and in this opinion I am more convinced than ever. It is well known that old plants of Lapageria extend but slowly at the extremities of their shoots after these attain a certain height. The strongest growths come from the root or near it, and these always make most growth during the season. But it is not necessary to have roots to begin with, as young shoots layered their whole length produce shoots from each joint just as strong as those from roots, and at the same time make roots of proportionate strength and size. What can be done with the Lapageria in this way must be seen to be believed. The plan is considered to be a secret by some, and there is one extensive propagator of the Lapageria who closes his houses against inspection; but his plan is no secret. At the Handsworth Nurseries the white Lapageria is propagated for its flowers as well as for stock on a more extensive scale perhaps than anywhere else, and the propagating houses are open to all who choose to go and see for themselves. I saw there during the present week about 1000 plants of Lapageria alba that were not in existence at this time last year, and which are now not much more than six or eight months old. These plants were layered from nine older plants last autumn, and their shoots now average 6 ft. or 7 ft. each, and plenty range from that to 12 ft. I measured them with my foot rule. They will all grow some feet yet, and are now showing flowers. By October there will hardly be less than 10,000 ft. of young growths—all from a few plants, and they are there to be seen, and all in magnificent health. A stock nearly equal to this was cleared out last year; some idea may therefore be entertained as to the demand for this fine climber. The enormous rooting power of the Lapageria may be judged from the fact that a number of plants reserved for flowering purposes from last year's young stock are now in 20-in. pots, set like pot Vines along the front of a low house, and the shoots cover a roof 75 ft. long and 8 ft. high from end to end. Some of these plants have ten shoots or more, and many of the individual shoots are from 10 ft. to 14 ft. in length, and are growing and flowering.

J. S. W.

The Automatic Budder.—If this new implement will accomplish all that is claimed for it (p. 51), it will be a great acquisition to gardeners, but more particularly to nurserymen, to whom it will be worth about six men, according to Mr. Fish, who states that "exhaustive experiments" have proved that professional buddlers will be able to accomplish six times as much work by it as they would by the ordinary method. I can state from my own knowledge that the ordinary work of a professional Rose budder per day of 10½ hours is 600 buds, making and inserting them, a boy doing the tying, as would have to be done after the automatic budder also, I apprehend. Roses are the most awkward subjects to bud, but of fruit trees and shrubs a man can put in 1000 buds per day. In one nursery with which I am well acquainted, where from 70,000 upwards of Roses are budded every summer, besides a proportionate quantity of other things, the above figures represent every day's work for each man. It would appear, therefore, that the automatic budder will enable a man to put in 3600 Rose buds in a day and 6000 fruit-tree buds, or from about six to twelve buds per minute, without allowing for interruptions (?). Your correspondent says the description given in your pages "by no means exhausts, far less exaggerates, its merits." But particulars as to the actual work a man can accomplish by its use would give your readers a much better idea of its usefulness than anything else.—J. S. W.

The Orchis which you have figured and described in your last number as *O. purpurea* is *O. fusca*. With me it does not do as well in the garden as some of the other native species. *O. hircina* is again in fine bloom here, but nothing like as fine as last year, when the stalk was between 4 ft. and 5 ft. high.—H. HARPER-CREWE, *Drayton Beauchamp*. [According to Hooker's "British Flora," *O. fusca* is a synonym of *O. purpurea*.]

"The Parks and Gardens of Paris."—Messrs. Macmillan this week issue a cheaper edition of this book, published at the lower price of the first edition—18s.

THE INDOOR GARDEN.

POTTING ORCHIDS.

THE advice given by Mr. J. C. Spyers (p. 115) as to the desirability of potting Orchids before the young roots push forth, is worth printing in "letters of gold," and young gardeners and amateur Orchid growers especially would do well to bear it in mind. It takes all the skill of a very experienced plantsman to pot an Orchid when its young roots are protruding without serious injury being the result. Even if the tender root-points, with their gelatinous tissues, are not directly, *æ.*, mechanically, injured by abrasures, they are extremely likely to rot off if subjected to a covering of fresh compost. That the thick roots of many Orchids possess a wonderful and little understood power of discrimination in their earliest stages of growth is well known to close observers; they readily pierce the compost if it be sweet and porous and otherwise suitable; but they often altogether avoid it if, as not unfrequently happens, it is stagnant, too close, or otherwise unsuitable. Light, heat, and moisture alike influence the behaviour of root-growth, however, apart from the abstract question of suitable compost; and because we cannot exactly imitate Nature in these things, it follows that we cannot feed our Orchids by aerial means alone, as often happens in tropical lands. In the re-potting of Orchids it frequently happens that the roots cling so tenaciously to the pot that they become broken in shifting. Mr. John Bain, who years ago grew many rare plants to great perfection in the College Botanic Garden, Dublin, found that by placing the plants in a cool temperature and dry atmosphere for a few days, and withholding water at the same time (cautiously, of course), the roots relaxed their grasp of the pot, and could then be re-potted with but little damage. Looking at the rare *Phalaenopsis Esmeralda* in Messrs. Veitch's collection a week or two ago, I found its root-growth to be highly instructive. Its newly-formed and growing roots looked as healthy as possible, and were actually pointing upwards rather than down towards the compost—in a word, the genial moisture-laden atmosphere of the house in which it is growing is more enticing to them than the compost; and precisely the same thing may be noticed in the case of other species of *Phalaenopsis*, *Aerides*, *Vandas*, *Angrecums*, &c. To confine the roots of such plants in a mass of cold, wet compost, where they become blanched and etiolated, is but a very poor substitute for the genial life-giving atmosphere which attracts the roots, and in which they revel in all their plump and vigorous greenness. In Orchid growing the state of the atmosphere is ten times more important than any kind of compost whatever can possibly be; although it must, in most cases, be used for mechanical as well as chemical reasons, yet in the best grown collections we find a minimum of potting material is employed and a maximum of plant-growth is thereby attained. Too much heat and deficient atmospheric feeding has killed thousands of Orchids and other plants also, and the same may be said of large pots of compost, in which hundreds of Orchids are starved or suffocated year after year.

B.

Azolla pinnata.—An instance of rapid growth is well exemplified in this pretty little aquatic, which when received at Kew last autumn was not sufficient, as regards quantity, to cover 1 sq. in., while now it is spread over the surface of some of the tanks, which are several square yards in size; in fact, it appears to be quite a nuisance in the old Lily-house tanks, where it grows most luxuriantly and forms a dense green carpet similar to that of the common Duckweed, but much prettier in appearance, inasmuch as it looks like some of the small-growing *Selaginellas* floating on the surface of the water. It evidently thrives best on the surface of fluid mud, but it also succeeds satisfactorily in water of ordinary clearness and temperature. It is a capital subject for growing in indoor aquaria, and should be sought after for that purpose.—W. G.

Variegated Maples in Pots.—These beautiful fine-foliaged trees make very effective objects in pots or tubs for furnishing large conservatories in summer. We have some of the well-known *Acer Negundo variegatum* about 12 ft. high, and at this time of year their beautifully-marked foliage associates well with the ordinary summer occupants of conservatories; and I have no doubt that the newer varieties of Japanese Maples would be equally effective, as they have the advantage of being very easy plants to manage. Potted in good loam they would last several years, if well supplied with water, and a little liquid manure during the growing season. As soon as the foliage drops in autumn they might be plunged in leaves or tan in any sheltered spot, and remain until they were again required for decorative purposes. In fact, where decorations on a large scale are frequently in request, a surplus stock of such plants as these is ways valuable; as they are equally effective as the choicest

stove plants, and for forming backgrounds to large groups they often become available where, owing to the unsuitable position, one would hesitate to put valuable specimens.—J. GROOM.

THE BLACK AND GOLD WASP-COLOURED ONCID.

(ONCIDIUM CRÆSUS.)

GROWING only 1 in. or 2 in. in height, this is at the same time one of the most diminutive, as well as one of the most beautiful of Oncids. If rarity is any merit in a plant, then this one will for some have an additional attraction. Both pseudo-bulbs, leaves, and flowers are represented of the natural size in the annexed sketch, which we had an opportunity of making at St. John's Wood in April last, at which time a superb little specimen in the well-cared-for collection of Mr. Philbrick bore upwards of thirty fully expanded flowers. It was grown in a pan about 6 in. in diameter, and was much admired by all who saw it when exhibited at one of the Regent's Park exhibitions. The pseudo-bulbs are ovoid and slightly compressed, with indications of being fluted, and each bears a pair of bright green leaves. The flowers are borne two or three together on slender zig-zag spikes, and last long in perfection. The sepals and petals are nearly equal, varying in tint from greenish-umber to reddish-brown, with indications of darker nerves. The lip is of a brilliant golden-yellow (the

wealth of the aureolin no doubt having suggested the specific name), which is further intensified by the purplish-black blotch on its disc; this in some forms takes the shape of a blood-coloured ring around the verrucose crest. Purchasers must bear in mind the fact that only when in bloom can this plant be distinguished from several other forms less desirable, such as *O. Janierense*, *O. oxycanthosmum*, and *O. Janierense superbum*, which pretty nearly approach *O. Cræsus* itself in beauty. *O. longipes*, the Lindleyan species introduced by the Messrs. Loddiges many years ago from Rio, is in all probability the original type of the dwarf-growing race to which *O. Cræsus* belongs; but it is in this last-named species that the wasp-like colours of yellow and black reach their maximum point of beauty. The true plant is said to be Brazilian, and is no doubt, like many other fine forms of well-known and even old species, very rare even in its native habitats. Collectors now in Brazil are sending over *O. curtum*, *O. dasystyle*, and others, but the tiny Oncid we now specially allude to, yet would appear to linger unseen and unwrested from its home in the trees on the lower slopes of the Organ Mountains. To say that a plant comes from Brazil or the Organ Mountains, however, is about as intelligible as it would be to tell a foreigner that *Cypripedium Calceolus* is found in England. We had thought of this little gem as unrepresented in plant portraiture, but there is a plate of it in the second series of the *Floral Magazine*, t. 40, and *O. longipes* is also represented at t. 5193 of the *Botanical Magazine*. All good authorities agree that it succeeds best in a small pot suspended near the light in a moderately warm and airy Cattleys house, and that it should be freely supplied with moisture at the root when growing. Although such a very small morsel, even when in its utmost luxuriance, the flower is very large in proportion to the stature of the plant, if compared with the largest flowered of all the Oncids, *O. macranthum*, *O. Marshallianum*, or *O. varicosum* Rogersi. The quaint little *O. Limminghi*, however, is much smaller in its habit of growth, and bears a flower as large, if not still larger; but in neatness of growth, comparative rarity, and beauty of brown and gold, there is no rival to wrest the palm from *O. Cræsus*. F. W. B.

The black and gold wasp-coloured Oncid (*Oncidium Cræsus*).

ing and flowering most freely in a cool house filled with Tea Roses and Azaleas during winter and summer. The first flowers on the old wood are, of course, late, just being at their best about the middle of July, and the flowers on the young wood, which was extending rapidly, were showing at every joint. The plant is in fine health, and is 25 ft. long, and covers a great part of the roof. It has grown from a small plant in its present quarters, and is not yet three years of age, and is growing in a brick pit 1 ft. deep in a compost of peat mulched on the surface with cow manure.—J. S. W.

CONSERVATORY CLIMBERS.

ENQUIRIES are so often made concerning climbers suitable for conservatories that a few remarks on those which we have at present growing and flowering freely may perhaps be acceptable to such as contemplate planting in similar structures. I may mention that during the late severe winter the temperature of our conservatory ranged from 40° to 50°, heat only just sufficient to exclude frost, as being planted principally with permanent plants such as Oranges, Camellias, Daturas, &c., nothing like a growing temperature is attempted during the winter months. The climbers are planted out in well-prepared borders under the stone side stages which support the pot plants that are from time to time introduced. Taking them at the present time the most striking and fragrant are two plants of

Rhynchospermum jasminoides, that have clothed the pillars which support them from base to summit, as well as a considerable length of the drooping chains which we have festooned with creepers. Such treatment suits this lovely flowering plant much better than pot culture and formal training. Another excellent plant is *Tecoma* or *Bignonia jasminoides*, the deep green foliage of which looks well at all times, and its flowers with their light edges and red throats remind one of those of a *Gloxinia*. *Jasminum azoricum* is at present covered with a cloud of delicate bloom, and *Tacsonia Van Volxemi* is an indispensable climber, the brilliant flowers of which wave with the slightest breath of air. Its rapid growth too, and fine foliage render this plant extremely useful for clothing a lofty roof. *Mandevilla suaveolens* is a good white-flowered climber, but unfortunately it is rather liable to be attacked by insect pests, which in such positions are difficult to exter-

minate. *Metrosideros floribunda*, which bears singular bottle-brush-like flowers of a brilliant description, looks well as a pillar plant. Bunsian Roses, which under glass maintain their evergreen character, are also suitable for such positions, in which their dark shining foliage is very effective. Amongst Acacias some are well adapted for forming climbers; all of them succeed well under conservatory treatment, and they produce a fine display in spring. *Lapageria rosea* and *alba* are quite at home in a cool house, and flower profusely in autumn. The deciduous *Bignonia grandiflora* is also a fine autumn flowering climber, as are also some of the Clematises. We like the brilliant colours of *C. Jackmaui* and similar varieties, and are gradually introducing them and blending them with the evergreen ones such as *C. indivisa lobata*; in fact, many of our brilliant-flowered deciduous climbers might be used in such a way as not to leave unsightly bare spots in the winter, when indoor effects are most appreciated. For covering bare spaces rapidly we use *Cobæa scandens* and its variegated form with good results, as in very lofty buildings vigorous growth is required in order to give them a furnished aspect, while choicer plants of slower growth are growing up to replace them.—J. GROOM, *Linton Park, Maidstone*.

Stephanotis floribunda in a Cool House.—A plant of this in the Handsworth Nurseries, grown for its flowers and to afford a stock, being a wonderful free-flowering variety, may be seen grow-

The Fringed-petalled Hibiscus (*H. schizopetalus*).—One of the most remarkable plants now in flower in Messrs. Veitch & Son's nursery at Chelsea is this tropical Malvaceous plant, which is con-

sidered to be a variety of *H. Rosa-sinensis*, though, from its very distinct characters, together with its geographical source, it well merits specific distinction. It resembles *H. Rosa-sinensis* in its mode of growth, but the leaves are narrower and more deeply serrated. The flowers are 3 in. in diameter, borne on slender drooping stalks about 4 in. long, produced from the axils of the leaves on the upper portion of the branches. The colour of the petals varies from a rich deep crimson to a pale pink tinge, and they are deeply and elegantly fringed and reflexed, much in the same way as a Turk's-cap Lily. The golden-tipped stamens, with the protruding velvety styles, are arranged in a bottle-brush manner on the upper half of a slender tube from 1 in. to 2 in. long, thus giving the flower a singular appearance. It comes to us from Zamzibar, and we hope ere long to see it more commonly grown than at present.

ROSES.

THE BEST HARDY ROSES.*

WE have adopted the following means of determining the comparative merits of different varieties. Taking the five qualities required in the order of their importance, we assign the following number of points to each:—Colour, 24; form, 22; fragrance, 20; freedom of bloom, 18; vigour and healthfulness of growth, 16—making a total of 100 points. As will be seen from the table subjoined, we have no Rose which is quite perfect; our choicest sorts, excelling in some qualities, fall short in others. Where two or more varieties resemble one another, we have only retained the superior sort; thus Ferdinand de Lesseps and Maurice Bernardin are thrown out as being somewhat similar, but inferior, to Charles Lefebvre. This gives a list, therefore, of quite distinct sorts, those which are nearest alike being Alfred Colomb and Mme. Victor Verdier at the head, and they are sufficiently dissimilar to make both essential, even in a very limited collection:

Name of Rose.	Number of Points.	Total.
Alfred Colomb, crimson	24 22 19 15 13	92
Mme. Victor Verdier, crimson	24 22 19 14 11	90
John Hopper, carmine-rose	24 20 14 16 15	90
General Jacqueminot, velvety-crimson	24 16 17 17 16	90
Comtesse de Chabrillant, pink	23 22 17 13 14	89
Abel Grand, glossy rose	23 20 15 16 15	89
Marie Baumann, carmine-crimson	24 22 18 14 10	88
Charles Lefebvre, deep crimson	24 21 16 14 13	88
François Michelon, carmine-rose	24 11 15 15 13	88
La France, silvery-rose	24 22 20 18 3	87
Marguerite de St. Amande, bright rose	24 20 12 16 15	87
Climbing Jules Margottin, carmine-pink	24 19 14 14 16	87
Duke of Edinburgh, bright crimson	24 17 15 15 15	86
Baronne Prévost, rose	23 14 17 16 16	86
Louis Van Houtte, maroon	24 21 20 14 6	85
Paul Neyron, rose	22 19 13 15 16	85
Anna de Diesbach, carmine	24 16 12 14 15	81
Mme. Boll, carmine-rose	24 21 12 8 15	80
Prince Camille de Rohan, dark crimson	24 18 14 12 10	78
Countess of Oxford, carmine-red	24 22 4 14 13	77
Caroline de Sansal, rosy-flesh	23 15 12 14 13	77
Mme. Alfred de Rougemont, white	20 16 14 18 9	77
Peach Blossom, pink	22 16 10 12 13	73
Coquette des Blanches, white	23 10 8 18 12	71
General Washington, reddish-crimson	20 18 4 17 8	67
Marquise de Castellane, carmine-red	24 19 2 9 10	64
Baroness Rothschild, silvery-pink	24 21 2 12 4	63
La Reine, rose	15 12 10 12 14	63
Etienne Levet, carmine-red	24 20 2 10 6	62
Mlle. Eugénie Verlier, silvery-rose	24 20 2 8 7	61

A list of this kind would not be complete without mention of some summer Roses. Though blossoming only once a year, some of them, notably the Mosses, are so beautiful as to be essential to a Rose garden of any size or pretensions. We name the following as the best:—For climbers—Bennett's Seedling, Baltimore Belle, the Queen of the Prairies. Among non-climbers, the most desirable are Persian Yellow, Mme. Hardy, Mme. Plantier, and the following Moss Roses: Crested, Common Moss, Comtesse de Murinais and Salet; the latter, though less beautiful than the others, blooms freely in autumn, and would be quite valuable for that quality alone.

ALFRED COLOMB, which heads the list with 92 points out of a possible 100, is less fragrant than La France, more coy of its blooms than Coquette des Blanches, and does not have the lusty vigour of growth possessed by Baronne Prévost, but for the five qualities no sort altogether equals it.

MADAME VICTOR VERDIER is a sister variety of nearly equal worth.

JOHN HOPPER, always steadfast and true, comes third. Victor Verdier bears him much resemblance in colour and general appearance, but has neither the fragrance nor vigour of constitution to be counted a rival.

GENERAL JACQUEMINOT, notwithstanding a lack of fulness and rotund form, is now one of our oldest, most generally known, and best Roses for general cultivation. Clad in his rich crimson livery, he is still prepared to lead the van.

COMTESSE DE CHABRILLANT, possibly from the length of name, is a variety too much neglected and lost sight of. The flowers are not large, but most beautiful, and are models of symmetry and grace.

ABEL GRAND is another neglected, or at least not well-known, variety of the highest excellence, especially valuable in the fall of the year when competitors otherwise equally meritorious are devoid of even a semblance of bloom.

MARIE BAUMANN! How difficult to depict her charms; original and exquisite in all her features, she claims a choice position in every garden. There is no more beautiful variety than this in the entire list.

CHARLES LEFEBVRE is an improved Jacqueminot in form and possibly colour, though somewhat inferior in other qualities.

François MICHELON, a comparatively new sort, is rapidly gaining favour. It is a seedling from La Reine, bearing some resemblance to that well-known sort, but decidedly superior in colour and form.

LA FRANCE is the sweetest of all Roses; compelled to choose one variety, this should be ours. It is not only the most fragrant, but, with the exception of those Hybrid Noisettes, Madame Alfred de Rougemont and Coquette des Blanches, will yield more flowers during the year than any other sort named. It flowers so profusely that its growth is checked, every eye sending forth a flower-shoot: it is, alas, not very hardy, being the most tender on the list; but though the tops are killed, it will start out again in the spring from the roots.

MARGUERITE DE ST. AMANDE is a worthy companion of Abel Grand, furnishing a general supply of autumn flowers.

CLIMBING JULES MARGOTTIN, besides being of more vigorous growth, seems, if anything, more beautiful than the old sort, from which it is a sport. It is well worth growing for its buds alone.

DUKE OF EDINBURGH is a bright-coloured Jacqueminot, which is saying all that is necessary.

BARONNE PRÉVOST, one of the best of the flat type, is a worthy companion of General Jacqueminot, and a model of vigour and health. It is the oldest variety on the list, having been sent out in 1842.

LOUIS VAN HOUTTE, like La France, is but half-hardy, and is also worthy of extra care. No other sort so nearly approaches La France in fragrance, and when planted in a bed together, the deep velvety maroon of the one contrasts most beautifully with the delicate silvery rose of the other.

PAUL NEYRON is the largest variety known, and although its size detracts from our notions of a refined Rose, it is nevertheless a noble sort for any garden.

ANNA DE DIESBACH, a true carmine, has its rivals of the same shade, but her pure, lovely colour has never yet been equalled by any of them.

MADAME BOLL is almost worth growing for its large, lustrous foliage, but the blooms correspond in size and quality, only are too seldom seen after the June blossoming is over.

PRINCE CAMILLE DE ROHAN is a superb, very dark sort, very well known.

COUNTESS OF OXFORD, a splendid carmine-red, of the Victor Verdier type, is, like François Michelon, rapidly becoming popular, its chief defect being a want of fragrance, which it lacks in common with all the Victor Verdier race.

CAROLINE DE SANSAL is a well-known and justly popular sort.

MADAME ALFRED DE ROUGEMONT and COQUETTE DES BLANCHES are, all things considered, the best white perpetuals we have.

PEACH BLOSSOM, a comparatively new sort, seems to improve each year, and gives a new shade of colour that is very desirable.

GENERAL WASHINGTON, one of the most widely disseminated varieties, does not reach the maximum number of points in any quality. In colour it is somewhat grand, but generally it has somewhat of a faded appearance, being quickly affected by the sun, and seldom seen truly pure. The same may be said respecting form—sometimes superb, but generally with some defect, either a green centre or unsymmetrical. Of fragrance it is almost entirely devoid. It ranks very high as a free-bloomer, but, like La France, this is at the expense of growth.

MARQUISE DE CASTELLANE does not always open well, but gives many large carmine-rose blooms of globular shape that are truly superb.

BARONESS ROTHSCHILD has exquisite cup-shaped flowers, entirely distinct from all others. It is, unfortunately, of stubby, short-jointed growth, and can only be propagated by budding or grafting. This will always tend to make it somewhat scarce.

LA REINE is another well-known old Rose which we cannot yet afford to discard, though now surpassed by so many finer varieties.

* Abstract of a paper read before the Western New York Horticultural Society.

ETIENNE LEVET, somewhat resembling Countess of Oxford, is rapidly finding favour, and, had it but fragrance, would be assigned a higher position.

MIDLE. EUGENIE VERDIER, the last of the list, is certainly one of the most delicately beautiful coloured varieties we have, but here again the lack of fragrance deprives it of a higher position.

We have given the shade of colour in case any one should desire to select from this list, with reference to having but a few sorts quite distinct from each other in tint; but as already mentioned, Roses vary in colour as in form, and we may have two kinds, of precisely the same shade, yet strongly differing in every other respect, and therefore entirely distinct. HENRY B. ELLWANGER.

MR. BAKER'S ROSES.

In the very favourable notice of my Roses at Norwich by Mr. D. T. Fish (p. 82) I am asked to "reveal my Rose secrets." This I will most readily do, but as my blooms are simply the "legitimate outcome of careful culture," and not "nourished into size, moulded into form, and coloured perfectly by some specially rich food," I fear he may be disappointed at the meagreness of my revelations. In the first place, my blooms were not the produce of "dwarf maidens," but were all of them grown on cut-back plants (Manetti), most of which were five years old. It has long been my opinion—and every year's experience tends to strengthen it—that the blooms from cut-back plants are superior in every respect to those from maidens, and more especially so in finish and form. My Rose ground was very carefully prepared in the first place, being trenched to the depth of 2 ft., and made very much like a sandwich, with alternate layers of manure and earth. In this my plants rooted capitally, and they throw up every year strong shoots from the bottom. For example, last autumn I measured some from Charles Lefebvre, which were more than 9 ft. in height, and this season they are still making fine growth; indeed Mr. A. J. Soames, who paid a visit to my Roses a week or two ago, expressed his surprise at my having such strong shoots so early in the year.

About the middle of August I have the greater part of the old wood cut out, in order that the young rods may have plenty of light and air to enable them to ripen properly, and from this wood I get my show blooms for the following year. In November I give my plants a good dressing of thoroughly rotten cow manure; this I have dug in at once, as I do not like it to remain on the surface during the winter. In March, after the pruning is complete, the ground is lightly forked, and after that occasionally hoed up to the time of blooming. As soon as the bloom-buds are formed, I give the plants plenty of liquid manure, composed of sheep droppings, soot, and a little guano, and sometimes, in a wet season like the present, I sow a little guano; but I much prefer the liquid manure.

With regard to protection of the blooms, I have not shaded or in any way covered a single Rose during the whole of the season. On the day before the Norwich Rose Show we had a gale of wind and very heavy storms of rain, and I quite despaired of being able to show my Roses in good condition. However, I directed two men to keep shaking the blooms all day so that the rain might not remain long in them, and in the afternoon the weather cleared up, and the Roses were pretty dry by the time we began cutting at six p.m. We finished staging at 9 p.m., left Exeter at 10.10 p.m., and reached Norwich at 9.10 a.m. on the following morning. I think the cool nights were the cause of the Roses bearing so long a journey so well, as I have found this year that I have been able to cut larger and rather older blooms than I can generally venture to do. I think I have now told Mr. Fish all that I can about my Roses, and I will only add that if he or any other Rose grower would like to pay me a visit, I should only be too pleased to see them. I only hope that they will come either during the last week in June or the first week in July, and then I can generally promise them a sight worth seeing; but at all events I can always promise them one thing, and that is—a very hearty welcome.

Heartree.

R. N. G. BAKER.

Rose Show in August.—Mr. Fish is quite right in saying (p. 82) that when the huge buds at present upon Rose trees do open they will be a sight to see. I am one of the hon. secs. of a flower show to be held here on August 15, and we consider we did wisely in fixing so late a date; certainly we have had the weather in our favour. Now I wish to make a suggestion to Mr. Fish and his friends. The Rose show held last week in Birmingham was too early for this season. It was not a good one in any respect. Here we are establishing a floral and horticultural society seven miles from Birmingham and Walsall and not much further from Wolverhampton. We have the Midland and North-Western lines running through

the town, and without doubt Sutton Coldfield is becoming the fashionable and most popular place of resort in the Midlands. Our flower show is to be held in Four Oaks Park, and if Rose growers will care to help us in our first attempt by sending us a few boxes of bloom for exhibition, the committee here will undertake to receive them, stage them, and return the boxes after the show. We cannot do much more, but it may be of some advantage to the growers; and as our sole object in holding a show is to stimulate a love of horticulture, we shall be perfectly well satisfied if the sight of well-grown blooms promotes a rivalry between our local amateurs and the nurserymen.—JAMES B. CULL, *Sutton Coldfield.*

Tea Roses on High Ground.—The fact that frosts are often far more severe in the valley than on the hill-side is well known to fruit growers. Tea Roses, also, frequently bear witness to the fact that frost is more severe in low ground than on that which is elevated. Mr. George Paul's nursery at High Beech is on much higher ground than his nursery at Cheshunt, and he takes advantage of this to grow a superb collection of Tea Roses at High Beech, where their beauty just now is delightful to see. They are mostly standards in the highest state of beauty and vigour, notwithstanding this most exceptionally severe season. The fact is worth noting by all who have an opportunity of growing these Roses on high or hilly ground. It is fair then to suppose that Tea Roses do not suffer from deficiency of heat so much as from winter-killing. There is no doubt that the valley is the warmest place except at night; but, nevertheless, the fact is worthy of notice that even the slight elevation of these low and beautiful Essex hills makes a great difference in the culture of a most beautiful group of Roses. Even much slighter elevations might be very beneficial to them.—V.

THE FRUIT GARDEN.

SUMMER PRUNING.

In a season like the present, when there is so marked a deficiency of light from the almost constant obscuration of the sun, the importance of keeping the young growth of fruit trees thin cannot be over-rated. In many gardens such fruits as Apples, Pears, and Plums are thin, and the trees are making a good deal of wood; and unless a check, or, better still, a series of moderate checks are given, the systems of the trees will become disorganised through the impetus the roots will receive from a large leaf surface, which is destined ultimately to be removed. It is the delay or neglect of summer pruning which mainly causes the trees to lose their balance, and renders root-pruning necessary to restore it again. When the young summer growth is permitted to run away too much, the produce is usually smaller, as the strength of the tree is carried upwards to form twigs and foliage (all of which, beyond a certain necessary process, is wasteful expenditure), instead of being utilised in increasing the bulk of the fruit. And not only does it act prejudicially in this way, but it shuts out the sun-light, and prevents the creolation of air, without which fruit can neither be large in size nor fine in quality. It is well enough known that the fruits are not so fine on unpruned trees, or where the pruning is neglected, as on trees that are properly cared for. I am not referring now to orchard trees, although in their case, if the necessary skilled labour could be obtained, there is plenty of scope for its employment; but as every man one meets is not competent to perform a surgical operation on the human subject, so many men that are employed in pruning and thinning fruit trees have neither had the necessary training nor possess the necessary intelligence for the work. That over-pruning may be as great, or even a greater evil than leaving the trees altogether in a state of Nature, I readily admit; but no one who understands the subject would seriously recommend either alternative, although one often meets with people who, having practised one extreme, fly off at a tangent to the other.

With trained trees, or those growing in a confined space, the chief aim in the majority of soils should be to keep the roots near the surface, where, in dry summers, mulching could be resorted to for the purpose of supplying the trees with food. The quantity of water evaporated from a good-sized Apple or Pear tree on a warm, bright summer's day must be something enormous, and if this water cannot be found by the roots near the surface, downwards they must go for it; and, as a rule, the damper the soil the more luxuriant the young growth becomes, and the less likely is it to become firm enough to produce at any future time fertile blossoms. There, of course, comes a time, usually sooner rather than later, when root-pruning must be resorted to in order to balance the forces of the tree; but, if the tree had been gradually built up, with its roots kept near the surface by mulching, and its summer growth judiciously thinned and shortened, a good deal of time, and perhaps some dis-

appointment, would have been saved. I was much struck last year by the high colour and large size of the fruit on a number of small Apple trees that had been raised from cuttings several years ago. This year again, although Apples are scarce, the little trees are heavily laden with good-sized fruit for the season. The fruit is finer because the roots are near the surface, and, beyond a certain necessary progress, the whole of the forces of the tree are employed in fruit production, either present or prospective. Trees that annually bear a sufficient crop of fruit do not, as a rule, waste their energies in the production of surplus wood. The crop of fruit steadies them, and acts as the best and most natural check upon exuberance of growth. In the summer management of fruit trees there is plenty of scope for intelligence of the highest order.

Fruit trees vary very much in character: some are robust and vigorous, others are constitutionally delicate. Again, some commence growth early in the season, and require prompt attention; others are later in demanding the cultivator's care. Therefore, it will easily be seen that no hard or fast line can or should be laid down, either as to the time or the mode in which summer pruning should be done. But, speaking generally, the top of the tree should be pruned, first permitting a little more development to the leaders than to other shoots. The strongest shoots should be stopped first, cutting back to about four or five good stout leaves. Some good fruit growers divide the summer pruning into three periods, doing the top portion first, then the middle of the tree, and the bottom portion last. This system of pruning is based upon the known fact that the sap flows more freely upwards in direct lines than laterally or horizontally along the lower branches; and by pruning the top of the tree first, the outlet for the ascending sap is for the time blocked, and its force is directed into the lower branches, in the same way as a current of water may be stopped and turned in an opposite direction by damming up the stream. No doubt, in the course of time, the top will regain its ascendancy, but still, by careful management of the pruning, there should be no difficulty in keeping each portion of the tree under the influence of a rapid healthy circulation, and the balance between the various parts fairly well maintained. And moderate-sized, well matured wood is more likely to be obtained by giving a series of small checks—by dividing the pruning into periods of ten days or so—than by cutting all the young growth off at once as is commonly done.

E. HOBDAY.

KENTISH FRUIT GARDENS.

ON Friday last a party consisting of some fifty horticulturists, chiefly from the neighbourhood of London, made an excursion to Swanley to see the extensive fruit gardens which abound in that district, and also to visit the nursery of Mr. Cannell, which is wholly devoted to florists' flowers. The glass ranges are extensive and form a compact whole so that they can be easily heated. Several of the houses were gay with Pelargoniums of all classes and in endless variety, but more particularly those of the zonal type both single and double flowered. By a method of skilful culture and with the assistance of light houses, so arranged that the plants can be placed near the glass, the whole of the plants, which are of moderate size, are in vigorous health and flowering profusely. The collection of tuberous rooted Begonias was at its best and made a grand display, filling one house entirely. It comprised most of the varieties of merit, of which a few are particularly noteworthy; viz., Wonder, a vigorous-growing kind, dwarf in growth, with foliage similar to that of *B. Pearcei*; its flowers are of good form and size, and are rich yellow in tint with a flesh-coloured tinge in the centre, the tips of the petals being suffused with the same colour. Such beautiful kinds as *Acme*, *Paul Masurel*, *Massage de Louvrex*, look well when grown into large specimens, as does also the chaste-flowered *Queen of Whites*, a very appropriate name for this variety. *Verbenas* receive particular attention at this nursery, as a house filled with the best varieties fully showed. Amongst them might be seen almost every conceivable shade of colour, and their adaptability for greenhouse culture as well as for bedding purposes cannot be overrated. A decided advance, too, has been made in these with regard to size of truss and form of the pips, points well exemplified here. *Abutilons*, *Coleuses*, *Carnations*, in fact all kinds of florists' flowers, are grown more or less largely in this nursery. The present season has rendered it rather premature to comment on the *Dahlias* grown here as there are not many yet in flower, and the same remark applies to the general stock of out-door bedding plants, such as *Pelargoniums*, *Lobelias*, *Alternantheras*, *Calceolarias*, &c., to which a large area is devoted. The *Snapdragons*, however, are well worth a passing note, for they are very gay and represent some remarkable colours, from the purest white to the deepest crimson as well as bright yellow selfs, and in some a combination of several colours arranged in stripes. The stiff marly loam hereabouts is apparently well fitted for the

growth of *Roses*, as Mr. Cannell's collection is looking in fine health and producing an abundance of bloom. There are also large plots occupied by *Strawberry* plants, a fruit to which especial attention is paid here.

After examining the contents of the nursery under notice, the party took a walk through the adjoining fruit fields, the *Strawberry* crops in which are in full bearing. The soil consists, for the most part, of a stiff clayey loam, and apparently not easily worked. Most of the small fruits thrive remarkably well on it, especially *Strawberries*, than which it would be difficult to procure better anywhere, either as regards size, flavour, or productiveness. The kinds principally grown appeared to be *Sir Joseph Paxton*, *Dr. Hogg*, *Eleanor*, *Premier*, *British Queen*, *Garibaldi*, &c. A thin layer of clean straw is placed round the plants about the time when they are in bloom, and this effectually keeps them clean. Gathering the fruit for market by scores of men, women, and children was an interesting operation, as was also the expeditious way in which it was packed in baskets for transit. *Raspberries*, too, are largely grown here, and cover an area of many hundred acres. The crop of these is also heavy. The red-fruited kinds are those grown principally, but only such as are of the *Fillbasket* character. They are cultivated in rows without stakes or other supports, and they did not appear to require any; the canes, being cut back to about 3 ft. at the winter-pruning, stand quite erect and bear abundantly. *Currants*, chiefly the red and black varieties, are grown extensively in the locality, as are also *Gooseberries*, which, by the way, were severely injured by the caterpillar, many of the trees being completely denuded of leaves.

Orchard fruits do not appear to receive much attention in this part of Kent, as the orchards passed through consisted chiefly of worn-out Lichen-covered trees, and the untilled condition of the surface did not lessen this impression. On some of the farms *Potatoes* formed an important crop, and the soil appears to suit them admirably, as more healthy plots of them are seldom seen. The ubiquitous disease, however, has shown traces of its presence, though not as yet to a great extent, and probably the present more favourable weather may keep it in check. For the purpose of cleaning the land, and also to alternate the crops, *Wheat* and other cereals are cultivated, and also *Hops*, fields of which were passed through, and, as far as can be seen at present, a productive yield may be anticipated, though their growth does not seem equal to that made in more favourable seasons. They are, however, pretty free from insect pests.

W. G.

Dying off of Apricot Branches.—Those who take an interest in *Apricot* trees, and watch their progress with a practised eye, may often perceive a few weeks previous to the fall of the leaf a tendency in certain branches to indicate incipient debility by a weakly growth, and a certain flaged and hang-down appearance in the foliage. This is the usual forerunner of the dying away of the branches in the spring. When the sap is on the move, they make a feeble effort, throw out a few small leaves, and then collapse and die. The causes of this are still wrapped in mystery; but I have known it to follow after excessive fruit bearing, and also where the necessary manipulations through the growing season have not been sufficiently gradual, where too much has been removed at one operation thereby checking the abundant flow of the sap, thus causing gumming, and sowing the seeds of future debility. Another great outlying cause is the deficiency of the water supply during the swelling of the fruit previous to ripening, and again after the fruit is gathered, at which time the borders should be well saturated, which will plump up the buds, and cause the wood to look fresh and bright. In the final pruning, therefore, look well, in the first place, to see that the wood has this appearance of plumpness and health, and remove at once any of a debilitated and doubtful appearance. Then look to the condition of the tree, as to its being evenly furnished; and if overcrowded in any part, let it be judiciously thinned out there. The practice of training in plenty of young shoots, will leave a very useful margin to enable the operator to bring up young healthy wood in any needful direction, and also to make provision for prospective vacancies, by leaving as much young wood as possible low down in the centre of the tree as reserve, even at the risk of a little crowding. The trees may then be carefully trained out equally all over the surface, using as few nails and shreds as is consistent with security, and allowing supreme symmetrical training to be subordinate to the general welfare of the tree.—*Florist*.

Heavy Crops of Peaches.—I see in the *GARDEN* of Saturday last (p. 105) that Mr. Cowburn of Sunbury Park gathered 330 dozen of *Peaches* off one tree and 250 dozen off another; is not this an error? I have a large tree which produced 23 dozen fine fruit, and there was no space for more.—R. H. [The figures in question are printed correctly according to Mr. Cowburn's statement.]

GARDEN DESTROYERS.

GREEN FLY, ROSE APHIS, OR ROSE BLIGHT.
(SIPHONOPHORA ROSE.)

THIS insect is one of the large and destructive family called aphides, which is only too well known to all who have given the slightest attention to the cultivation of plants. It may be classed without hesitation among the gardener's worst enemies, as there are few plants which do not suffer more or less from the attacks of some members of this family. Those, however, which belong to the Natural Orders Fumariaceæ, Gentianaceæ, and Iridaceæ are said to be entirely free from them; and Cryptogamic plants and Labiates nearly so. The family aphides contains a very large number of genera and species, which are widely distributed throughout temperate countries, but they are almost unknown in the Tropics. The Rose aphis is unfortunately one of our commonest species, and the injuries which Roses sustain from it are well known to every lover of these flowers (and who is not?). Few Roses are exempt from their attacks, but the Tea-scented kinds and those whose leaves are somewhat evergreen suffer less than others. These insects are often called blight, and many persons assert that when during northerly or easterly winds in dry weather there is a haziness in the atmosphere, that haze is blight, and caused by immense multitudes of

1. Winged female; 2. pupa; 3. larva; 4. ditto just born; 5. wingless female; 6. side view of winged female showing the position of the wings, at rest; 7. profile of head. Lowin; the protosias.

these insects, and urge, as a proof of their theory, the very sudden appearance at times of myriads of these aphides. These insects have not, however, anything to do with atmospheric effects. No doubt they often make their unwelcome presence known in large numbers, and plants may be found covered with them which only a few days before were apparently free from them; but this, no doubt, is due to many of the eggs hatching at the same time, and to the very rapid manner in which their re-production is effected. Most of the females are viviparous, that is, they bring forth their young alive instead of being enclosed in an egg; and so fast do they multiply, that a viviparous female which I was watching gave birth to two young ones within half an hour. This seems, however, to be an unusually rapid rate. Mr. Buckton, in his most interesting and valuable work on the British Aphides (one of the Ray Society's series), states that he has known eight to be born in six hours from one female. One of the peculiarities of this very interesting and remarkable group of insects is that some of the females never lay eggs, but always produce their young alive, whilst others lay eggs and never reproduce in any other way. The young which are born alive begin to produce young in the course of from four to eight days, so that the rate at which they multiply is very astonishing. Prof. Huxley has calculated that the tenth generation alone (not including the previous ones), if all the members survived, would contain more matter than 500,000,000 stout men (more than the population of China), assuming that an aphid weighs 1-1000th of

a grain. Mr. Buckton calculates that the living progeny of a Rose aphis, supposing that each aphid lived twenty days and gave birth to twenty young, at the end of 100 days would be 3,200,000, and at the end of 200 days 10,240,000,000,000. When we consider these figures we may indeed be thankful that, owing to their very numerous enemies, we are not more troubled with these pests. Another very curious fact about aphides is, that the impregnation of one female by the male is sufficient for many succeeding generations, so that a female having paired is not only rendered fertile, but her progeny for many generations also without any intercourse with the males on their parts.

The Rose aphis does not entirely confine its attacks to Roses, but infests Dahlias, Asters, Verbenas, and many other plants cultivated under glass. The injuries it occasions to plants when in large numbers is very great, as it deprives the young and tender parts of so much sap, causing the leaves to crumple up and preventing the buds from flowering properly. Numberless plans have been tried for their destruction, but in seasons favourable to their growth it is almost impossible to keep Roses grown out of doors free from them. Those grown under glass, however, can easily be kept clean by fumigating them with Tobacco smoke. This plan cannot, however, be so easily carried out with Roses growing in beds out of doors; still, by covering the head of the plant with some kind of air-tight cloth, well tied round the stem, the green fly may effectually be killed with the assistance of a fumigator. The cloth should be stretched over a frame, which anyone could make, to keep the buds and young shoots from being injured. Carefully brushing such parts of the plants as are infested with spirits of wine, benzine, or 1 wineglassful of paraffin to 4 gallons of water kept well mixed is very effective, as it kills the flies at once. Simply brushing such parts of the plants does a great deal of good, as many are killed by the operation, and the others, once knocked off, cannot well return (except the winged ones). Crushing the aphides on the trees with one's finger and thumb is a very effective, but unpleasant method of destroying them. Syringing with Tobacco water, or a weak solution of sulphate of copper (1 oz. to 6 gallons of water), or an infusion of Quassia chips (4 oz. of chips should be boiled for ten minutes in a gallon of soft water, and 4 oz. of soft soap should be added as it cools); or 2 lb. of washing soda, 1 oz. of bitter aloe dissolved in hot water, when cold add 1 gallon of water; or 8 lb. of soft soap dissolved in 12 gallons of rain water, added to 1 gallon of Tobacco water; or water in which Tomato leaves have been macerated, are receipts which are much recommended; even cold water when applied with some force is very effective. M. Lachauve, in THE GARDEN of the 10th May, recommends the use of a disc of sheet metal, about 2 ft. in diameter, with a slit from the edge to the centre about 1½ in. wide, fastened to a handle; before using it the disc should be smeared with gas-tar, pitch, or something very sticky. It is then placed under the head of a Rose bush, the stem passing through the slit; the branches must then be tapped to make the aphides fall on to the sticky plate, from which they cannot escape. The difficulty in this plan is to dislodge the insects by merely tapping the branches.

Fortunately these insects have an unusual number of natural enemies. Besides the insectivorous birds, which destroy great numbers of them, several species of small wasps carry them off to fill the cells in which their grubs are bred. The grubs of the common seven-spotted and two-spotted ladybirds, the grubs of the lace-winged fly (described in THE GARDEN of the 1st of March), and of certain two-winged flies very common in gardens, which may often be seen hovering over flowers, and apparently remaining motionless in the air for some seconds together, belonging to the family Syrphide, destroy the aphides with wonderful rapidity. The last-mentioned grubs will suck out the contents of the body of a full-grown aphid in 1½ minutes, and will kill several one after the other as quickly as they can suck them. Numbers of the green fly are destroyed by very minute parasitic insects belonging to the Ichneumonide. These little four-winged flies get on to the backs of the aphides, and plunging their ovipositors into their victims, lay their eggs within them, which soon hatch, and the grubs before long destroy the aphides. Those which contain parasites may easily be recognised by their brown, hard, and distended appearance. Very rapid changes of temperature seems to check the multiplication of aphides. A heavy thunderstorm will often kill thousands, and cold rain is very destructive to them. This season, which has been so unusually wet and cold, the Roses have been particularly free from them in most places. The eggs, which are laid in the autumn, do not hatch until the following spring, when all the aphides which are hatched are wingless females. These in a few days begin to produce young, which are borne alive, and very much resemble their mother in general appearance, but their legs and antennæ are much shorter in proportion (see fig. 4). After some changes of skin they assume the form shown in fig. 3, and after further moultings, either show the rudiments of wings, as in fig. 2, or else are in an intermediate

state between figs. 3 and 5. When in either of these stages, this insect may be said to be in the pupa state. Changing their skins again, they appear as perfect insects, those with the rudimentary wings as alate, or winged females, as represented in fig. 1; those without as apterous or wingless females, as shown in fig. 5. The winged females assist greatly in the increase of their species, for being able to fly they can easily move from one part of a bush to another, or fly off to other plants, founding fresh colonies wherever they may settle. They are not so abundant as the wingless ones, except in the spring and autumn, when they frequently migrate in great numbers. About the middle of September the last generation is usually produced, which consists of males and females. The former are sometimes winged, sometimes wingless; they are very much like the females, but are somewhat smaller. The females are mostly wingless and viviparous. After pairing with the males, they lay their eggs, which are very large in proportion to the size of the insect (nearly half the size of its body), a few together near the buds. They are long and oval, and when first laid pale yellow, but soon afterwards become black. They are covered with a slimy coating, with which the female attaches them to the plant.

These eggs hatch in spring as before mentioned. M. Lachaume, in his article on "Insects Hurtful to the Rose," says that "what naturalists have hitherto taken for eggs are nothing more than the last brood of aphides, which assume a thick black coat in order to stand the winter's cold." This must surely be a mistake, for though some of the viviparous females survive the winter, such accurate observers as Mr. Curtis and Mr. Buckton both speak very positively of the eggs. There has often been much discussion as to the origin of what is usually called Honey Dew, that sticky substance one frequently finds on the leaves of Sycamores, Limes, &c., and also on garden seats which have stood under trees. It seems now to be generally admitted that it is secreted by aphides, which are furnished with two organs, placed near the end of their bodies, called cornicles, through which they secrete a sweet, sticky fluid, which, as the insects are generally feeding on the undersides of the leaves, falls on to the upper surface of the leaves below. The Ant is very fond of this fluid, and will gently tap the sides of an aphid with its antennae in order to make it exude some; as soon as a drop appears the ant at once swallows it. M. Lachaume, in his paper which I have already quoted, states that "ants will suck these insects to death in a very short time." The observations of other entomologists do not, so far as I know, in any way confirm this, nor has a case ever come under my own notice. It would be very much like killing the goose which laid the golden eggs on the part of the ants. The Rose aphid in its earlier stages is almost entirely of a pale green colour, its eyes, antennae, legs, and cornicles being somewhat darker; and the three last-mentioned organs much shorter in proportion than in the maturer forms. Its head is furnished with a long proboscis or rostrum, which is in three joints: when not in use it is carried between the forelegs of the insect. With this instrument it obtains the juices of the leaves or young shoots on which it lives; it is not, however, inserted into the plant, but it serves as a sheath for three long hair-like organs, which the insect can protrude from it, and with which it pierces the leaves with a saw-like motion. These organs are neither barbed nor toothed, but a plentiful supply of sap flows from the incision they make, which the insect sucks through its proboscis with a pumping action. In all its stages the insect derives its nourishment in this manner. After changing their skins, their bodies take a more oval form, and are capable of being very much distended, which is usually the case when plenty of food can be obtained, when the joints of the body can with difficulty be seen; when food is scarce the edges of the body turn up and form a kind of wavy ridge. In the winged state the insect is about $\frac{1}{2}$ of an inch long. The head and eyes are black; the antennae are very long, 2-10ths of an inch, and delicate, and consists of seven joints, the two first being short, stout, and rounded, the third long, the fourth and fifth rather shorter, the sixth short, and the seventh very long and tapering. These last two are nearly black; the others are brownish, with darker tips. The thorax is greenish-black, more or less dark. The body is oval, pale green, with nearly black spots, and cornicles; the latter are long, round, and slightly tapering. The legs are very long. The thighs are green, with blackish tips, the shanks brownish with black tips and feet. The upper pair of wings when open measure about $\frac{1}{10}$ ths of an inch across; they are long, narrow, and very simply nerved. The lower pair are much smaller and the nervures still simpler; on the upper edge they are furnished with a small double hook, with which during flight they are attached to the upper pair. All the wings are slightly iridescent. The wingless females are about $\frac{1}{4}$ of an inch long, and are somewhat pear-shaped. Their heads and bodies are entirely pale green; their eyes are dark reddish-brown; their antennae are brownish, with darker tips to the joints, and are not so long as their bodies; the legs are brownish with darker tips to the joints. This insect is sometimes of a pale reddish-brown.

G. S. S.

ANSWERS TO CORRESPONDENTS.

Fruit Nets.—How can I best preserve fruit nets from rotting? I have tried a mixture of tar and colza oil, but the nets have not dried, though they were dipped some months ago.—E. L. T. [I do not think that it would pay any one to dip their own nets with the view of preserving them, seeing they are now manufactured so cheaply for garden purposes that new ones made in any width or size of mesh may be obtained for the same money at which second-hand fishing nets have but recently been supplied. Mr. Eddy, Porthleven, Cornwall, will supply nets that, if only kept dry when not in use, will last for a number of years. Dipping in tar and oil would be useless expense if the material of which the net is made is not of good quality.—JAMES GROOM, Linton Park, Maidstone.]

Salt v. Worms.—How much salt to the gallon of water may be safely used to destroy or bring worms to the surface of a lawn?—A. B. [Salt is a somewhat dangerous material to apply to lawns. If used stronger than from 4 oz. to 6 oz. to the gallon the Grass will be likely to suffer at first, and later in the season will grow rank and coarse, so that except in extreme cases it would be better to depend on frequent sweeping and rolling, as even if the salt proved a remedy at first, it would soon lose its effect.—J. G.]

Hanging Baskets.—I have just purchased three fancy wire baskets each about 24 in. in diameter to hang in my stove. Will you kindly inform me how to fill them effectively?—J. D. [For covering the outside of basket No. 1, use *Cemimelyna agraria variegata* and *Selaginella Kraussiana*, let a plant of *Russellia jucea* occupy the centre, and surround it with three or four plants of *Cissus discolor*. For basket No. 2 cover the outside with *Tradescantia zebrina variegata*, plant *Begonia foliosa* in the centre, and surround it with *Selaginella uncinata* and *Stenotaphrum glabrum variegatum* planted alternately. For basket No. 3 plant within the margin and the outside with *Panicum variegatum* and *Selaginella Galeottei*, and use *Nephrolepis davallioides* for a central plant. The central plants should be good specimens, such as have been well rooted in 10-in. or 12-in. pots. Line the baskets with a thin layer of tough peat, and plant the outsides before filling them. The first growths of the trailing plants should be pegged to the baskets, but the after growths may be allowed to hang free.—C. M.]

Quick-growing Trees.—What trees are most suitable, on account of their quick growth, to conceal an objectionable background, where the soil is fairly deep and good, in fact inclined to be heavy? and what is the smallest space that should be allowed between each tree, so that it may grow properly?—T. W. H. [For quickness of growth and effectiveness as a screen, nothing amongst deciduous trees surpasses the new Canadian Poplar, cuttings of which will, upon suitable soil, attain a height of 20 ft. in three years. Next to this for producing speedy effect may be reckoned the black Italian Poplar, and the Huntingdon Willow, both of which may be propagated from cuttings. A few pollards of any of these will yield an abundance of croppings fit for the purpose. By inserting short cuttings—say 2-ft. lengths—in front, and then gradually increasing the height of the standards, used up to 6 ft. or 8 ft. for the back row, a furnished appearance will at once be given to the whole space. The distances between the plants or cuttings used should depend very much upon the depth available for the screen. If this be but shallow, thicker planting will be necessary to produce the desired effect, say about 6 ft. from tree to tree; but with greater depth from 8 ft. to 10 ft. will be found enough. If near to some of the larger truncheons, a few plants of the true Irish Ivy (*Hedera canariensis*) are inserted, they will rapidly climb up, and afterwards hang in festoons from the heads of the pollards, thus filling up intermediate spaces, but their growth is slower than that of the trees just named. Norway Spruce in the front lines would be very effective. A good previous trenching of the soil and the addition of some light lime compost will greatly facilitate the growth of the trees; and thick planting, with early and careful stopping, foreshortening, and thinning, will produce a good screen in a very short time.—A. J. B.]

Names of Plants.—A. F.—1, *Centaurea macrocephala*; 2, *Lilium croceum*; 3, *Campylopus latifolia*; 4, *C. nobilis*. *Deron*.—1, *Clematis viticella*; 2, *Fuchsia virgata*; 3, *F. globosa*. *P. R. C.*—1, *Adiantum tetraphyllum*; 2, *Nephridium molle*; 3, *Cheilanthes farinosa*; 4, *Pteris scaberula*. *N. B.*—*Ophiopogon spicatus*. *W.*—Varieties of *Ixia* and *Sparaxis*. *W. L.*—We cannot undertake to name Roses. They can only be named with certainty by those who grow them. *F. W.*—*Cordylone australis*. *S. S. Y.*—The yellow netted-leaved plant is *Lonicera brachy-poda*; the other, *Jasminum officinale*. The small scrap is a species of *Scdum*. *W. H.*—The annual Beardgrass (*Polygouon monspeliensis*). *D. M.*—*Diplacis glutinosus*. *N.*—1, *Sedum Lydium*; 2, *Spergularia rubra*; 3, *Thymus citridomus variegatus*. *Adversho*.—1, *Aspidium venustum*; 2, *Phlebotium aureum*; 3, *Adiantum hispidum*; 4, *Goniophlebium subauriculatum*; 5, *Leucostegia immersa*; 6, *Polygouon pectinatum*; *Polystichum capense*; 14, *Asplenium bulbiferum*; others have numbers misplaced or are too much withered for recognition.

Diseased Rose Leaves.—*P. F. G., Cork.*—Your Rose leaves are badly infested by a fungus named *Phragmidium mucronatum*; the Rose-rust and the Rose-mildew are also present. Cures for these pests are at present insufficiently known.—W. S.

Clove Carnation.—*W. S. C.*—The bloom of your seedling sent to us is large and fine in form, bright in colour, and well worth perpetuating.

Questions.

The Pennsylvania Lawn Mower.—Have any of the readers of THE GARDEN had any experience of this lawn mower, which was introduced last year (1878)? Does it do its work with more ease than those with rollers behind the cylinder? It is said to be lighter, as regards draught, than any other mower. Any information on these points will be gladly received.—J. ALLSOP, Dalton Hall, Hull.

Palms for the Open Air.—Can any of your readers inform me whether *Chamærops Fortunei* (the hardy Palm) and *Corypha australis* would live if planted in the open air in Berkshire; the latter has been in a cool house for some time. Also whether *Bambusa Metake* and *Gymnothrix latifolia* would also live in the open garden.—F. C.

Summer Flowering Orange Crocus.—Mr. George Maw, of Benthall, Broseley, asks us to mention that he received through the post on August 1 from an anonymous correspondent the fresh flower of an Orange Crocus, which appears to be distinct from either of the known autumn-flowering Orange species. As he cannot ascertain either from the handwriting of the address or the post-mark to whom he is indebted for this interesting contribution, he would be much obliged if the sender would communicate with him and give him particulars of the origin of this summer flowering Orange species of Crocus, which is probably new to science.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

THE HEAVITREE ROSES.

It is quite evident that Mr. Baker's Roses were what is called by our Yankee cousins an "eye opener" to the Rose grower of East Anglia, who had not had the opportunity of seeing them at our great metropolitan exhibitions, and it will perhaps surprise Mr. Fish if I say that wonderful as were the blooms at Norwich, he would be still more astonished if he could see them at home. Some time ago I happened to see them at an exhibition at Exeter, and it will readily be conceived that they must be finer in such a case. We all know how fleeting are the hues of some Roses; those exhibited at Norwich had been probably cut twenty-four hours or more, so that some of the bright tints of the scarlets and delicate hues of the pinks had begun to fade; but when brought fresh from the garden, half a mile distant, not having had to endure the jolting and confinement of a railway journey of some 300 miles, it is impossible to forget the beauty of the stand to which I allude. It is not even like seeing them in the garden, for here the very best are culled from an extensive collection of the very best exhibition varieties, each exhibited to the best advantage, and placed so that the Rose lover can take in all their beauty. It is not, however, to be supposed that Mr. Baker is the only exhibitor who can show in this style; his celebrated rival, Mr. Jowitt, of Hereford, is so near him that they have each won the fifty guinea cup given by Mr. Cranston to the National Rose Society, and it was to have been decided this year which of the two was the better man, but by mutual consent the contest, owing to the exceptionally bad character of the season, has been postponed until next year.

There is no secret in the manner of growing the Rose, as practised by Mr. Baker, but there are some plain things which he does not forget, open to every one who attempts, as he does, exhibiting on a large scale, while in one or two things there are points in his favour not within the reach of all. The climate of Devonshire, and of Exeter especially, is peculiarly favourable to the growth of the Rose, soft and genial, generally exempt from severe frosts, although, strange to say, this year it has suffered more than counties usually cold. The greater humidity of the air is also favourable, for, where soil is favourable, Roses delight in moisture; it is only on heavy clay lands that it is injurious to them. Some of the very finest growth I have seen this year has been in Scotland, in places where the rainfall is just double what it is in the south and east of England, where east winds prevail more, and are more trying in their effects.

The soil in Mr. Baker's garden is well adapted for Roses; it is a good rich loam, not perhaps so good as some, such as the deep, unctuous loam of Hertfordshire, or Hereford, or Essex, but still a thorough Rose soil; now although care and skill may to a certain extent improve an unfavourable soil, yet the Rose grower who has one which is naturally good has an immense advantage, as I suppose most persons would recognise in whatever class of plants they are interested. Some soils absolutely refuse to grow good Roses, and others do so with great difficulty.

These are the two points on which alone Mr. Baker can claim a superiority over some Rose growers, certain y not over all; in those that follow it requires only means, and that love without which all else is of little avail. He grows a very large number of Roses, many thousands—how many I do not at present recollect, but it may give some idea of the extent to which enthusiasm will carry Rose growers to state that Mr. Jowitt last autumn huddled 3700 Roses in order that he might successfully compete for the challenge cup; he had whole rows of Duke of Edinburgh, La France, Charles Lefebvre, Marie Baumann, &c., with from 50 to 100 plants in each. Mr. Baker knows which are exhibition kinds, and, instead of filling his garden with doubtful sorts, he goes in for those only which are likely to be useful to him when the day of contest comes round. His plants are all dwarfs on the Manetti alone, I believe—at least, they were so two or three years ago; that he would grow as good on the seedling Brier I do not for a moment doubt, but he is unwilling to discard an old friend for an untried one. It is clear, I think, from the experience of this season, that for early Rose shows the Manetti is alone to be depended on; the seedling Brier not, as the blooms come later on it, and those Rose growers who looked to it to supply them with blooms

were disappointed. Mr. Baker does not keep his plants very long—a couple of years used to be his limit, but I believe now he keeps them longer; thus they have all the vigour of youth, and nothing could be more beautiful than the even rows of plants with which his garden was filled when I saw it.

As to cultivation, he feeds his plants tremendously; the amount of the very strongest manure that Rose trees will assimilate is something remarkable. I have seen some beds with nearly 1 ft. of manure on them, and yet they only seemed to rejoice the more for their very liberal supply. Mr. Baker farms as well as gardens; he is famous as a prizetaker for his breed of Guernsey cattle, and other matters; he has, therefore, at hand what the Rose delights in—the manure from the pig-sties especially; "pity 'tis, but true," that the delicate perfume of La France or Marie Van Houtte should be elaborated from such material, but such is Nature's chemistry, and both size and perfume are obtained in this way. Of course, Roses will grow without such supplies, and equally of course such treatment will not improve the appearance of the garden, but I am not writing of such matters, but only of the way in which these grand exhibition Roses are grown by Mr. Baker and others. Then the bushes are carefully dis-budded; no stem is allowed to carry more than one flower, and only a limited number on each plant. Mr. Fish limits the bunches on his Vines, and thins out his Grapes, and on the same principle Mr. Baker manages his Roses. Lastly, as the time draws near, and the buds most likely to be useful are approaching maturity, they are shaded both from the scorching rays of the sun (but little of this has been necessary this year) and also from rain, which is so apt to damage the leaves. It would, perhaps, be needless to add that to all these things Mr. Baker adds an intense love for the Rose, and is possessed of great energy and perseverance; without these, and the direct personal superintendence which such qualities imply, such success as he has attained is not to be secured.

I do not know whether this will meet Mr. Fish's requirements; there is nothing new in it, but for all that I believe it contains all the information that is to be had concerning the method in which those Roses to which he alludes were produced, and if I have omitted aught, I shall be glad, if possible, to supply the omission if Mr. Fish will notify it.

DELTA.

—Rosarians must feel proud—I can answer for one of the oldest and largest of the brotherhood—and they who wish to be Rosarians must feel thankful when they read Mr. Baker's unselfish, unreserved, and instructive letter (p. 135) concerning the cultivation of the Rose. Very few men would be thus candid, generous, and large-hearted in freely presenting to others the results of a long and costly experience; and all of us, including those whom he has vanquished in our bloodless wars of the Roses, must rejoice in his success. I would ask to make two brief remarks in the same spirit, and with the same intention with which he has written, namely, to promote the popularity and to extend the dominion of the Queen of Flowers: Firstly, that the Manetti stock, on which Mr. Baker grows his beautiful Roses, will not suit all soils; and, secondly, that, although the blooms from "cut-back" trees are, as a rule, the most reliable, because, as a rule, the poor "maidens" are frost-bitten in that terrible season which we persist in calling spring, there are times, nevertheless (all the more glorious because of their rarity), when the bud, uninjured and unchecked in its growth, and attaining the perfect fulness of Rosehood, will exhibit that development of form, colour, size, and foliage as shall make the astonished owner sigh in admiration.

S. REYNOLDS HOLE.

Caunton Manor, Newark.

ROSES ON TREES.

As a pendant to Mr. Ellacombe's paper on Roses on trees (p. 99) allow me to describe a Rose arrangement in my garden which was in great beauty till destroyed by the heavy rain of last Tuesday. I have two large Cratæguses, round-headed standards, growing close together, so that their edges touch, forming, as it were, two gentle hills with a valley between, and sloping down to within about 6 ft. of the lawn. Of these one is *Cratægus Crus-galli*, the other *C. tanacetifolia*. Behind, and partly through these, climbs a very old Noisette Rose—all that now remains of an arched trellis—producing a vast number of bunches of white flowers, six or eight together and about 1½ in. or 2 in. across. The old gnarled stem of the Rose is scarcely noticeable amongst those of the Thorns till it reaches the top of them, whence it descends between the trees in a regular torrent of blossom, in addition to occupying the topmost boughs of the Cockspur Thorn. The general effect is almost that of a large patch of snow between two bright green hills—a combination very common in the higher districts of Switzerland. A smaller plant of the same Rose has recently been trained up a large *Arbor-vitæ* which, from moving, has lost its lower branches for some 4 ft. or 5 ft., and

has its stem clothed with Ivy. It is now festooned with snowy flowers hanging down from and against the dark green of the Arbor-vitæ and Ivy, forming a charming contrast. It seems a great pity that we do not oftener thus wed one tree to another—a stout and strong to a slender and clinging one, as Virgil in the "Georgics" talks of wedding the Vine to the Elm, as is, I believe, done to this day in Italy. Did we do so we should oftener verify the motto that gardening—

Is an art
Which does mend Nature: change it rather: but
The art itself is Nature.

Monkstown.

GREENWOOD PIM, M.A., F.L.S.,

THE TIME OF ROSES.

BY THE REV. CANON HOLE.

THE time of Roses, when the Americans are kind in their arrangement of the weather, and when there is nothing seriously amiss with the perihelion, commences about the middle of May, and ends in November. The tide of our glorious Red Sea begins to flow at the date specified, reaches high water at the end of June, remains in full flood until the middle of July, and then slowly ebbs, until, congealed by bitter frosts, it becomes a Dead Sea, or Mer de Glace, in December.

And as the visits of royal personages are announced on city-walls, so the advent of the queen of flowers is foretold by the mural Roses. These are the advanced guard of the reginal retinue, and a Marshal of France—Maréchal Niel—in all his golden splendour, claims the honour, with handsome invincible Gloire de Dijon for his aide-de-camp, to precede the army. Then the hedgerow Roses, representing the love of a loyal people, line the route of the royal progress:

"The road shall blossom, the road shall bloom,
So fair a queen has left her home."

Where, when, and how shall we see this royal progress best? My reader, if I knew your habitat, I could probably tell you of some *point d'avantage* near to your home; but, not having this information, I will give you a list of our most distinguished Rosarians throughout the country, from the Land's End to the Border, hoping thus to introduce you to some scene of beauty which you can readily reach, and where Roses bloom in all their glory. The Rose merchants will welcome you, of course, because you can no more leave their nurseries without giving an order for Roses than a young lady can leave London without buying a bonnet; and the amateurs, I am sure, knowing them well, will be glad to see you—your quest of the beautiful (not to mention your good taste in reading this paper) being a guarantee to them of mutual sympathies.

In Devonshire, the native home of the exquisite Rose *Devoniensis*, there is the nursery of Messrs. Curtis & Co. at Torquay, whence came the seventy-two Roses which were the first to bloom of all the Roses in England, and consequently to take the highest honours at the great show of the National Rose Society held in June at the Crystal Palace; and also, in this favoured county, there is the famous Rose garden of Mr. Baker, one of the most successful of our generals in the Wars of the Roses, at Heavitree, near Exeter. In Wiltshire, at Salisbury, there is the nursery of Messrs. Keynes & Co., from which some of the grandest of Roses have been sent to our shows; and at no great distance there is the Stapleford nursery, where Mr. Bennett has recently raised some most interesting seedling Roses, and among them, as he announces, that *summum bonum* and roc's egg of the Rosarian's hope—a yellow perpetual Rose! In Sussex there are the Woodlands nurseries, near Maresfield, where Messrs. Wood & Sons have their *rosea rura*, their farm, acre after acre, of Roses; and also the gardens of Messrs. Mitchell, at Piltedown, of long success and renown. In Kent, Messrs. Kimmont & Kidd have recently sent from Canterbury an excellent collection of Roses, for which they won a premier prize; and in this "Garden of England" the amateurs are numerous, notably Mr. Hollingsworth of Maidstone, Mr. Burnaby-Atkins of Halsted, and Captain Christie of Buckhurst Lodge, Westerham (in whose honour Monsieur Lacharme has named one of our most attractive Roses), who realise their favourite in their perfection. In Essex, Mr. Cant, of Colchester, can write *nulli secundus* over the entrance of the Mile End nurseries, when his Roses are in their glory. In Hertfordshire, I saw last year, and on a summer's eve, 40,000 standard Rose trees in one plat (only a moiety of the Cheshunt nursery of Messrs. Paul & Son), glowing in the soft splendour of the setting sun, some of the most brilliant varieties—such as the Duke of Edinburgh, Sultan of Zanzibar, and my namesake, Reynolds Hole—being indigenous to the soil, born in that beautiful garden. Hard by, about a couple of miles, are the extensive and picturesque grounds of Messrs. William Paul & Son, famous for their "pictorial trees" as well as for Roses. These adjoin the Waltham Station, so that visitors by rail pass from the platform into

the nurseries, and, having enjoyed their manifold delights, including many charming Roses sent out by Mr. William Paul, such as Beauty of Waltham, Star of Waltham, May Quennell, *cum multis aliis*, may hire a fly for Cheshunt. The nurseries of Messrs. Lane of Berkhamstead, and of Messrs. Francis of Hertford, are also famous for their Roses. In Middlesex—that is to say, in the neighbourhood of London—the best Rose nurseries are those of Messrs. Lee of Hammersmith, Messrs. Fraser, Lea Bridge, and, just out of Middlesex, in Surrey, those of Messrs. Veitch & Sons at Combe Wood and Kingston Hill. Amateurs abound, but the one who produces Roses most accessible to her Majesty's lieges is my friend Mr. Scott, who brings every morning during the time of Roses, and from his garden nigh to Wimbledon, a beautiful display for his desk at No. 1, Old Bond Street. Passing into Buckinghamshire—and the G.W.R. will take you in less than an hour to Slough—you will find there, in the royal nursery of Mr. Charles Turner, one of the best collections of outdoor Roses, and the best collection of Roses in pots to be seen in England; and near to Slough many amateurs, of whom Mr. Hawtrey is chief; and thence, returning to the rail, you may leave the main line at Didcot, and in the suburbs of Oxford, queen of cities, you may find delightful little gardens of Roses most carefully and successfully tended by college servants and others.

Leaving these pleasant gardens, you must make your way back to the city, and ask Mr. Prince, of the Market Street, to show you his nursery of Roses upon the cultivated seedling Brier, and to explain to you the advantages of the system, which he has himself introduced, by those practical illustrations which put an end to doubt. At Worcester may be seen, in the spacious nursery of Mr. Richard Smith, a most complete collection of Rose trees for sale; and in the neighbouring county, and in the King's Acre Nurseries, close to Hereford, the invincible Roses of Mr. Cranston, such as he exhibited last year at Manchester, to the dismay of all competitors, and to the delectation of those who did not compete. And in this picturesque and pleasant shire many amateurs, true lovers of the Rose, such as the Rev. C. H. Bulmer, Rector of Credenhill, an enthusiastic expert, and the chief founder of the West of England Rose Show; the Rev. Berkeley Stanhope, Rector of Byford; and Mr. Jowitt of the Old Weir, who is reported to be the happy possessor of more Rose trees than belong to any other of his unprofessional brethren. In Warwickshire I have seen Roses in their full integrity in the gardens at Leamington, and Messrs. Perkins & Co. of Coventry have been successful exhibitors. In Northamptonshire, Mr. House, of the Nurseries, Peterborough, is a skilful grower of Roses; but I do not remember, despite the numerous votaries of horticulture, any amateur Rosarian of note. So in the adjoining county, Messrs. Wood & Ingram, of the Nurseries, Huntingdon, are the chief representatives of those who delight in Roses; whereas in Cambridgeshire a most accomplished amateur, Mr. Curtis of Chatteris, divides the honours with Mr. Farren of Cambridge, once an amateur, but now a grower for sale, and so proficient in his clever manipulations that he has budded eleven hundred stocks in a day, thus changing by his legerdemain the common Brier into a thing of beauty; and in Norfolk and Suffolk the amateurs have undisputed sway—*les trois frères*, the Messrs. Fellowes (one of them—E. L.—of credit and renown in the history of Oxford cricket), true scions of a floral family; and Mr. Nichol, gardener at Dringston Park; and Mr. D. T. Fish, being the lord-lieutenants of Queen Rose. And this is the case in other neighbouring counties; the Rev. Mr. Pochin, Rector of Barkby, taking precedence in Leicestershire; the Rev. C. C. Ellison of Bracebridge, and Mr. Arthur Soames of Irnham Park in Lincolnshire. In my own county, Nottinghamshire, we are well represented in both departments, having two nurserymen—Mr. Merryweather of Southwell, and Mr. Frettingham of Beeston—who grow the Rose in abundant perfection; and a troop of amateurs, of whom I claim, in my venial pride, to be captain, and who may be numbered by hundreds among the working men of Nottingham. In their tiny gardens, nigh unto the town, may be found such specimens of their favourite flower as cannot be surpassed in the world; and you shall see many an artisan with a Maréchal Niel or a Charles Lefebvre in his Sunday-coat almost large enough to run away with him. In Lancashire, Cheshire, and Yorkshire, the only amateur of note with whom I am acquainted is the Rev. C. P. Peach of Appleton-le-Street; but there are prince-merchants of the Roses in the two firms of Dickson at Chester, in Mr. May of Bedale, and in Mr. Harrison of Darlington.

Next comes the inquiry, when is the time of roses? at what hour of the day shall we find them in their happiest phase? They are most beautiful, I think, at sunrise, when the queen of the flowers wears her glittering crown of diamond dewdrops; but where is the man who would rise so early in the morning (saving always the M.F.H., to watch the *début* of his young hounds in the coverts), and who shall venture to sing, "Come into the garden, Maud," when my lady sleeps her first beauty-sleep, and doors are locked and shutters are closed, and the other inmates might mistake her for a ghost

or a burglar? and the grass would be dank for her exquisite toes, however high and dry she might feel with reference to her lovely heels. And, therefore, I will invite you, knights and ladies both, to view the Roses when, after a bright warm summer's day, the evening sun is low, when the petals, which have drooped in the noontide heat, revive in all the freshness of their charms, and seem to be rejoicing in their thankful rest.

How, in what frame of mind and body, shall you enjoy this time of roses? After a day's good work, whatever your work may be, after a good dinner, with a good conscience and with a good cigar.

My reader has your time among the Roses inspired you with a yearning to have Roses of your own? If so, you may rely upon the instructions following, as the result of thirty years' experience.

Despise not the day of small things. You must learn your notes before you play a sonata. Devote a bed in the best part of your garden, sheltered but not overshadowed, having an eastern or southern aspect, as a throne for the garden queen.

Let the soil be well drained and dug.

Go to the nearest nursery where Roses are successfully grown, and order the quantity which you require from this list:

Alfred Colomb	Madame Lacharme
Baroness Rothschild	Madame Victor Verdier
Charles Lefebvre	Mademoiselle Annie Wood
Duke of Edinburgh	Mademoiselle Eugénie Verdier
Dupuy Jamain	Mademoiselle Marie Rady
Edward Morren	Maréchal Vaillant
Etienne Levet	Marquise de Castellane
François Michelon	Marguerite de St. Amand
John Hopper	Sénateur Vaisse
La France	Xavier Olibo
Madame Clémence Joineaux	

If this quantity does not satisfy your ambitions, then add:

Ahel Carrière	La Duchesse de Moruy
Annie Laxton	Louis Van Houtte
Baron de Boustettin	Mademoiselle Marie Cointet
Beauty of Waltham	Mademoiselle Thérèse Levet
Captain Christie	Maurice Bernardin
Camille Bernardin	May Quennell
Countess of Oxford	Monsieur Noman
Comtesse de Serenye	Miss Hassard
Dr. Andry	Mrs. Baker
Duke of Wellington	Pierre Notting
Emilie Hansburg	Prince Arthur
Exposition de Brie	Prince Camille de Rohan
E. Y. Teas	Princess Mary of Cambridge
Ferdinand de Lesseps	Reynolds Hole
Fisher Holmes	Star of Waltham
General Jacqueminot	Thomas Mills
Jean Liabaud	Victor Verdier

To these you must add, for some warm border, backed by a wall, the following varieties of the Tea-scented Rose:

Adam	Madame Villermorz
Aline Sisly	Madame Nabonmand
Auna Ollivier	Madame Welch
Catherine Mermet	Maréchal Niel
Cheshunt Hybrid	Marie Van Houtte
Comtesse de Nadaillac	Monsieur Furtado
Duchess of Edinburgh	Niphotos
Duke of Connaught	Perle de Lyon
Devoniensis	President
Homer	Rubens
La Boule d'Or	Souvenir d'Elise
Madame Bravy	Souvenir d'un Ami
Madame Margoltin	

Tell the nurseryman the nature of your soil, and he will judge as to the best stock for your Rose trees. The cost will be about 1s. 6d. each. Plant in November; prune in March. Be liberal with farm-yard manure. When the soil is set, keep it open with the hoe. Look out in May for the "worm i' th' bud," and, having him between your thumb and finger, do not wait to discuss with him the pros and cons of capital punishment. Above all, never be disheartened—only learn to labour and to wait, and you shall surely see in your own garden the time and prime of Roses.—*Time*.

Climbing Roses.—Amongst the many things which we have to talk of as being neglected, climbing Roses certainly ought to find a place. Considering their beauty, it is astonishing how seldom one sees anything like a good effect produced by them. This is chiefly owing to an over-severe manner of pruning, which is also wrong as to the season at which it is done. Climbing Roses, well developed and pruned, so as to be a mass of flowers at this season, might form the finest features of gardens at this time of the year, and yet one may see dozens of gardens without ever seeing a beautiful effect produced by a climbing Rose. The best way is to prune after flowering, and not to prune the shoots made afterwards, beyond a little thinning where that is necessary; in other words, avoid winter pruning altogether, then the shoots made in autumn would flower profusely the following year. Apart from giving them good soil, freedom from neighbours that rob them at the roots is as essential

to climbing Roses as to other things. The bowers, arches, and sheets of beauty which might be formed of them are endless, and will, we hope, some day be more commonly seen.—S.

Roses for the North.—It is well known that there are many varieties of the Rose which succeed well in the south that do not thrive in the north. Possibly, therefore, the following list of good sorts that will succeed in the north in unfavourable districts will be acceptable to your readers:—

Alfred Colomb	Louise Van Houtte
Baroness Adolphe de Rothschild	Madame Fillion
Beauty of Waltham	Madame Nachury
Boule de Neige	Mademoiselle Eugene Verdier
Captain Christie	Maréchal Vaillant
Comtesse de Serenye	Marie Baumann
Dr. Andry	Marquis de Castellane
Duchess of Caylus	Miss Hassard
Duchess de Vallambrosa	Mons. Etienne Dupuy
Duke of Edinburgh	Mons. E. Y. Teas
Edward Morren	Monseigneur Fournier
Etienne Levet	Oxonian
Fisher Holmes	Sénateur Vaisse
John Hopper	Star of Waltham
Jean Liabaud	Sir G. Walseley
La France	Triomphe de France
La Rosière	Victor Vigier

Our soil is heavy and stiff, and the Roses are mostly worked on the Brier. The list includes both new and old sorts that are good growers and free bloomers in such situations.—J. S. W.

FLOWERS FOR HOSPITALS.

THERE is much interest taken in providing flowers for the sick poor, but I constantly hear the time expended in gathering them begrudged. Such complaints certainly emanate from those who do least, as is always the case; but I fancy that if those who make them considered a little, they would come to see that it is a gain of time and flowers to cut them regularly and timeously. Here we cannot afford our gardener's time to be spent on what I can do quicker myself, and therefore I speak from practical experience. Beginning with the earliest blue flowers, viz., *Symphytum caucasicum* and *Anchusa empervirens*, by cutting and preventing seeding we have a longer supply of flowers and are saved the nuisance of seedlings coming up everywhere and through everything, and, like *Papaver orientale*, *Symphytum* roots are not easy to get rid of. *Centaurea blue* and the white *C. montans* should never have a flower wasted, and there will be a second crop in a few weeks. The centre spike of *Lupinus*, *Aeonites*, and *Delphinium* cut before the very topmost buds are expanded ensure a far better crop of side shoots, and in such a season as we have had of wind and rain, had these heavy heads been left, they would have broken down the whole plant or quickly damped off. All agree in the need there is of removing old Roses, and I am sure it is easier to cut them when in perfection and save the litter of fallen petals. I do not believe that flowers last longer in hospitals and in the dwellings of the poor than elsewhere; therefore double Roses should be cut in perfection and not in bud, for they do not expand satisfactorily in water, and have not so much perfume in that state. Single Roses should be sent in bud, but there are few gardens in which these are to be had in profusion. *Poppies* (*Papaver orientale*, *bracteatum*, *spicatum*, and *nudicaule*, so often called *alpinum*) and all *Iris* should always be sent in bud, and I have heard expressions of extreme surprise and delight at the sudden expanding of such buds and the unexpected colours exhibited. In short, granted that the old flower-stalks must be removed by some one for the sake of tidiness and the good of the plants, surely it is better that they should never be allowed to reach an untidy and unsightly state. We perhaps lose a great mass of bloom for two days or so, but we gain a good bargain for our charity in the continuous crop of flowers which we reap, and in tidiness and saving in staking and tying.

I have been asked to send Roses and *Rhododendrons* with longer stalks, and the proverb of looking a gift horse in the mouth has flashed through my memory; but I simply declared that for no hospital should plants be hurt, or the germs of new growth for next crop of bloom be taken. Of course, if the arrangers of the nosegays wish to tie up together a 2-in. stalked Rose and a 2-ft. spike of *Lupin*, they will fail. Our *Lupinus* were very fine, but it would have been pure selfishness had the pang of cutting the centres out not been instantly repressed. In the case of shrubs, a succession of flowers can be obtained in the shape of an ungrudging supply of *Ribes*, *Syringa*, and *Philadelphus*, not a bunch taken here and there, but the wholesale cutting over of a bush or two. The flowers of the *Lilac* should be denuded of their pair of young wood shoots, which do not stand in water and needlessly fill up the baskets. I do not deny that we are at the mercy of

the season in the case of such experiments, but we gain more than we lose.

I would strongly advocate once more the importance of always sending pieces of sweet smelling green plants along with cut flowers, such as Rosemary, Thyme, Lavender, and Gum Cistus, all of which retain their aromatic fragrance, and do not shed their leaves readily when neglected. That there is a want of such in the supplies sent is evidenced by the frequent requests for a basket of some sweet green material to mix with the flowers received. The Willow-leaved Sweet Bay (*Laurus nobilis salicifolia*), sometimes called *Oreodaphne californica*, which is smaller and sweeter than the common Sweet Bay, would be very useful. It seems but little known, and is worthy of all attention. A plant in a pot, 1½ ft. high, is very useful; and where standards of Sweet Bay and Laurel in tubs are used, the Willow-leaved kind would be a good addition and an improvement. I have, however, never happened to see it so employed. It makes an excellent wall covering. There are fine specimens of it at Dalkeith Palace and Newbattle Abbey. Mr. Dunn tells me that the dimensions of the plant at Dalkeith are 8 ft. high and 10 ft. wide; it has been where it now grows about thirty years, and would have been much larger, had it not been trimmed to keep it within its allotted space. If *Choisya ternata* proves to be as hardy (standing out such a winter as the past), it would be another very useful hospital evergreen, as, from its very leathery texture, it is perhaps the most enduring aromatic green-leaved plant with which I am acquainted, lasting any length of time in water.

Wardie Lodge, Edinburgh.

F. J. HOPE.

THE STATE OF KEW.

THE following statements, published in a leading article in the *Gardeners' Chronicle*, a journal never otherwise than friendly in its allusions to the authorities at Kew, will be read with some surprise:

"On Bank holiday (Monday) some 53,000 people visited the garden, but for their own protection sake, as well as for that of the plants, it was requisite to keep the houses closed, a walk through them entailing considerable risk from falling glass and falling rafters. Falling rafters! some will say—and think we are exaggerating. Unfortunately we speak the sober truth. It will come as a startling surprise to some to hear that in palatial Kew—our grand national garden—the finest establishment of its kind in the world—the rafters are in some of the houses so infested with dry rot and so rotten that a thrust with a stick suffices to bring them down. We have often had occasion to notice the disreputable and dangerous condition in which some of the houses are, such as the show-house, No. 4, the tropical Fernery, the succulent-house; but the full extent of the disrepair was not brought home to us till a day or two since, when looking round to see what damage had been done by the hail, we were astounded and disgusted at the dilapidated condition into which some of these structures have been allowed to fall. Nor is this rottenness confined to the older houses. In the T range, in the Victoria-house, which have only been built a few years, the rafters are not only rotten, but they are absolutely dangerous to the passers-by, to say nothing of the risk to the workmen on the roof. All this is so surprising, and so at variance with the general excellence of the administration at Kew—which we have, and justly, held up as a pattern Government establishment—that we quite expect our statements will be received with incredulity; but if any doubt let them visit the houses we have mentioned, and see if they will not then agree with us, that the structural condition of some of the houses is a disgrace and a scandal to a great national establishment. The fetters of red tape, and the indifferent *insouciance* of the Circumlocution Office (not of the officers of the establishment, who can only "represent") are to blame for this condition of things. My Lords, or the Board, or the First Commissioner, or some one, we know not exactly who, is responsible for this disgraceful state of things, which the present disaster at once serves to bring under notice and afford an opportunity of repairing. That in a wealthy country like ours the finest collection of living plants should be allowed to be endangered for the lack of a few pots of paint and a few deals, is an evidence of an amount of ignorance and carelessness on the part of those in authority which we can but stigmatise as disgraceful. For the prevention of railway accidents it has been proposed to make a director or a bishop ride on the engine of every train. To ensure the proper custody of the national property it would seem to need that a Lord of the Treasury or a First Commissioner should pass the night in one of the houses at Kew during such a storm as we have lately experienced.

Pleasant facts these for the public, especially for those who remember the noble liberality of the grant for the garden—

unexampled in any country. It seems hardly fair, however, to blame persons without the garden for the rotten state of houses "built a few years ago," and which must have been constructed with the approval of the garden authorities. Such statements as the foregoing are instructive when considered in relation to the aim, use, and enormous cost of these vast glass sheds, which are quite useless as regards our home wants, and not at all so important, even as they once were, in illustrating the vegetation of foreign lands, which through speedy inter-communication may be said to be now brought much nearer to us than they at one time were.

The Late Hail-storm.—I hope that something will be done to raise a subscription in aid of the sufferers in the Ealing, Brentford, Richmond, Isleworth, Kew, and Twickenham districts through the late storm. Mr. Hawkins, of Bayswater, has a large glass nursery, and his loss from broken glass and damaged plants is set down at something near £1000. Mr. H. B. Smith, Ealing Dean Nursery; Mr. Lane, the Grove Nursery; Mr. G. Weedon, St. John's Nursery; Messrs. Waylett & Son; Mr. Smith, Chapel Road Nursery, &c., are all heavy sufferers. The last four, who are jobbing gardeners and small florists, feel their losses heavily. Many jobbing gardeners, who have put up a little glass, have lost plants as well as glass, and these especially need assistance. At Brentford, Mr. T. Petridge, of the Boston Park Road Nursery, the well known grower of variegated Pelargoniums, is a heavy loser—indeed, well nigh ruined. I am doing what I can to awaken local interest on behalf of these cases, but it is desirable that a public effort should be made, as in the case of the hail storm of 1876; for owing to the adverse character of the season and the slackness of trade, many of the small florists are less able to bear their losses than they otherwise would have been. I know of some who would gladly form themselves into a committee to ascertain damages and administer relief, were any moneys forthcoming for the purpose. Assistance is really urgently needed; and remembering the generous response made in 1876, I trust that a similar feeling will be manifested on this occasion.—RICHARD DEAN, *Ranelagh Road, Ealing, W.*

TREES, SHRUBS, AND WOODLANDS.

CAMELLIAS IN THE OPEN AIR.

AFTER the late long and severe winter, a few words as to how our open-air beds of Camellias are looking may not be without interest to those who contemplate giving these lovely plants a trial out-of-doors. Camellias are at all times, when clothed with healthy foliage, beautiful objects to look upon, and of the beauty of the flowers and the variety of their colours it is difficult to give an adequate description. How to grow Camellias in perfection under glass has so often been discussed that I only need now call attention to planting good healthy plants in open-air beds in soil consisting of the top spit from an old pasture. Our soil is a moderately strong clayey loam, very much mixed with broken stone, locally called *hassock*, a soil that suits Apples, Pears, Peaches, and other fruit trees admirably. In this, when well mixed with leaf-mould or any gritty substance, Camellias grow luxuriantly, but, like the Grape Vine, although it is by no means an uncommon thing to see them dead or languishing under glass, one seldom finds one planted out-of-doors that does not grow freely in any kind of soil. Although green vegetables were severely cut by the frost last winter, and Myrtles and similar tender shrubs looked as if scalded, yet our Camellias continued as luxuriant as possible, and not a single bud dropped. On the contrary, every terminal growth was set with two or three very fine buds. Of course the usual plea will be set up that this is a favoured part of England as regards climate, but there are hundreds of places equally as favourably situated. I may remark that our very best plants stand in fully exposed situations on almost the highest ground that we have, while those planted against walls or under the shade of trees are by no means so luxuriant. I do not wish it to be inferred, however, that the Camellia is suited for exceptionally cold districts, where the thermometer runs down to zero; but our plants were exposed to all the frost that we had this winter, the ice close by them being from 6 in. to 8 in. thick for weeks, and the thermometer in very sheltered positions ranging from 10° to 17° of frost every night. I may add that Laurustinuses were much browned, so that any one who can grow Laurustinuses out-of-doors may safely plant Camellias. Spring frosts are destructive to the opening blooms, but as in many gardens it is not thought too much labour to protect Tulip beds and Roses for exhibition from the inclemency of the weather, it is surely not too much to expect that a little labour might be bestowed upon

a flower that is in some respects unexcelled. I feel sure that hitherto Camellias have oftener suffered from coddling than from any other cause.
J. GROOM.

WOODLAND WORK FOR THE END OF AUGUST.

EVERY operation preparatory to the planting season should now be vigorously carried on. The unkindly state of the land, consequent upon the continuous wet and cold weather of the spring and summer, renders it doubly necessary that during the present season draining, trenching, and holing or pitting should be well in hand. In order to facilitate the escape of water from the over-saturated soil, all open ditches and water-courses in the woodlands should be well scoured out and have their sides closely brushed, so that no impediment to thorough drainage may be interposed. Much of the mischief done to trees even in well established plantations arises from a neglect of this precaution. Instead of the ditches being deepened year by year as the roots of trees strike lower, they are too often allowed to fill up; and the result of this neglect is a slow growth of very inferior timber, especially upon the heavy clay soils which are to be found in various parts of the country.

The transplanting of large evergreens may now commence. Before uncovering the roots of these, see that every preparation is made for their speedy removal and replanting. At this season of the year the great secrets of success are quick transplanting, careful handling, warm weather, and sufficient moisture to start the growth but not to chill the roots. Great diversity of opinion prevails as to the necessity for pruning or foreshortening the head of a transplanted tree of the deciduous kind. This is supposed to be necessary in order to adapt the requirements of the head to the power of the roots, some of which must necessarily be injured, and all more or less temporarily paralysed, by the removal. The head and roots being correlative parts, the healthy growth of a tree must depend very much upon the maintenance of a proper balance between the two; so that when the latter become much lacerated and have to be cut back closely, some foreshortening of branches may be desirable. The maintenance of this equilibrium is more desirable and perhaps more necessary in young trees than in those of larger growth; for after the age of about twenty years the quantity of coagulated sap stored up in the trunk, and awaiting the first influences of spring to put it in motion, makes the tree more independent of immediate root action.

The advantages of early transplanting are many and great, for after the period of the fall of the leaf, though the growth of the season appears to be ended, it is found that as long as the soil remains warm, new fibres are found in it, and through the influence of these and the small amount of evaporation that takes place from the plant during the winter months, the roots become turgid with the accumulated moisture, so that the first warm days and showers of spring cause the tree to start off at once into vigorous growth.

If the head of the tree must be pruned for successful transplanting—and I am by no means inclined to think that this is necessary in the majority of cases—this operation is best performed at the time when the trench is opened out around it and refilled with compost. Action and reaction may thus be equalised. The cause of trans-

planted trees becoming stunted in their growth and attaining an early maturity in their new situations must be either improper treatment before removal, unskilful handling during the operation, or after neglect; or it may arise from unsuitability of soil and situation. An Oak removed into a deep oam with a clayey subsoil; an Elm or an Ash placed in a loamy gravel; or a Beech put into a calcareous gravel, resting upon chalk, will suffer little, if any, from the transplanting. One great source of mischief is placing the roots too deep in the ground, beyond the reach of the necessary heat and the proper action of the atmosphere. Those trees which have been frequently removed in the nursery generally suffer the least from transplanting.
A. J. BURROWS.

The Common Hop as a Climber.—Nothing gives the vegetation of our northern climate a more sub-tropical aspect than

The Common Hop as a Climber.

graceful climbers. Even the common Hop, as represented in the accompanying illustration, makes a capital plant for the purpose if allowed to ramble unmolested. For planting in woods, pleasure grounds, &c., it is admirably suited, as the rich vegetable soil generally found there, and the shade afforded by the trees, conduce to the development of ample foliage and long twining shoots. There are other hardy climbers, too, which could be used with equal advantage, such as *Apios tuberosa*, a North American plant of the Pea family, that bears reddish flowers with a perfume similar to that of Violet blossoms. The common *Tamus* (*T. communis*) is a pretty plant for a similar position, as is also the *Tamus*-like *Hablitzia* (*H. tamnoides*), a plant of rapid growth, and one which is covered for some weeks in summer with a profusion of small blossoms produced in dense racemes. The Cucumber family also yield some graceful climbing plants, for besides our native *Bryonia* (*Bryonia dioica*), there are *Echinocystis lobata* and *Thladiantha dubia*, both hardy and vigorous-growing plants. Several of the species of *Smilax* are quite hardy enough to admit of being grown in sheltered woods, and very pretty climbers they make when well established. The kinds best adapted for such purposes are *S. aspera*, *S. hastata*, *tamnoides*, *S. mauritanica*, and *S.*

excelsa. *Aristolochia Siphon*, as well as *A. tomentosa* and *A. altissima*, should always be included, as they will grow anywhere, but nowhere better than in sheltered shaded places. The Canadian Moonseed (*Menispermum canadense*) is another pretty plant, and one which has a charming appearance in early summer when covered with its long racemes of white feathery blossoms. *M. dauricum* is a kind not sufficiently known at present to speak correctly of its merits, but probably it is as desirable as its congener. *Schizandra coccinea*, a plant belonging to an allied family, and similar to the foregoing Moonseeds in appearance, is also well worth notice, as its small fruits, which are bright red, have a pretty effect. These are but a few of the many plants that could be advantageously used to beautify trees that may happen to have naked trunks in ornamental woods or in the wild garden.—W. G.

Big Trees.—There is at present on exhibition in New York a section of an immense tree which has been brought from California. The *New York Herald* says: "This wonderful specimen of Nature's handiwork was discovered in 1874. It was growing in a grove near

Tule River, Tulare county, California, about seventy-five miles from Visalia. Its top had been broken off, probably at some remote period, and when discovered it was still 240 ft. high. The body of the tree where it was broken was 12 ft. in diameter, and had two limbs measuring respectively 9 ft. and 10 ft. in diameter. The trunk measured below 111 ft. This ancient monarch of the forest is called "Old Moses," after a mountain near which it stood. It is supposed to be 4840 years old, and it is the largest tree that has ever been discovered. The section on exhibition is 75 ft. in circumference, and 25 ft. across. It is capable of holding 150 people in its interior. The interior, as it is now fitted up, is arranged like a drawing room. A carpet has been laid down; there is a piano, sofa, tables and chairs, with scenes from California hung round, and people move about quite freely.

BLUE-FLOWERED HIBISCUS.

(*H. SYRIACUS CÆLESTIS*.)

OUR gardens contain, perhaps, no hardy flowering shrubs—certainly none of the deciduous section—which are more strikingly beautiful than the different varieties of *Althea frutex*, the *Hibiscus syriacus* of botanists. They are perfectly hardy, they are very floriferous, they run into numerous well-marked varieties, and their flowers are in all cases exceptionally showy, so that there are few subjects that can be more safely recommended to the planter, and that may be more satisfactorily introduced to prominent positions in the shrubby borders. We have said that they run into numerous varieties, and we find in the catalogue of M. Simon-Louis upwards of thirty recorded by name, many of them being double-flowered; while M. Lavellé, in the *Arboretum Segrezianum*, remarks that the garden varieties are many.

Beautiful as are the old familiar sorts—that, for example, with white flowers having a deep purple crimson eye—they are eclipsed by this charming blue flowered variety of *H. syriacus*. We have seen it blooming during the past year or two in the nursery of Mr. A. Waterer, at Knap Hill, and have always found it most strikingly attractive; the colour, which sets off the richly coloured eye to much advantage, being one which is generally admired. It is called *Céleste*, or in the latinised form *cælestis*. It forms a free-growing plant, in habit and foliage resembling the other cultivated forms, and is remarkably free in producing its flowers. These are large and well expanded, of a beautiful cerulean blue, the purple-crimson eye remarkably rich, and radiating outwards towards the margin. Everybody who has a place for a choice hardy flowering shrub should plant this, and those who do so will not be disappointed.

Another very fine variety which we have also noticed at Mr. Waterer's is the *H. syriacus totus albus*, a pure white flower, and perhaps the most floriferous of all, the branches being thickly studded, throughout their whole length, by the very distinct looking flowers, which are attractive from their unblemished whiteness. Young dwarf plants flower copiously, and would no doubt form useful subjects for being gently forced into bloom in spring for conservatory decoration.

The two varieties here noticed are comparatively novel, or at least little known in this country, but they both deserve to be widely and extensively cultivated.—*Florist*.

Philadelphus Gordonianus.—This is a most useful and beautiful flowering shrub, one that should be in every collection, especially where there is a demand for cut flowers for filling vases or for bouquet making, almost rivalling, as it does, Orange Blossom in purity of colour. Some object to the common *Philadelphus* on account of its strong scent. The bloom of this is much larger, and it does not possess such a large amount of perfume. To those who have not yet grown this fine shrub I would say give it a trial. It will succeed in almost any soil as a bush. A few days ago I saw a plant of it growing as a standard, a form in which it had a good appearance.—*J. C. F.*

Syringas.—The following is a list of the species of *Syringa* recognised by M. Decaisne:—*A. Eusyringa*: flowers funnel-shaped. 1, *S. vulgaris*, Central Europe; 2, *S. oblata*, China; 3, *S. Euiodi*, N.W. Himalaya; 4, *S. Josikea*, Hungary; 5, *S. villosa*, N. China; = *S. pubescens*, Turczan; 6, *S. chinensis*; = *rothamagensis*; *S. dulcis*; *S. correlata*; *Lilas Varin*, *Lilas de Rouen*; 7, *S. persica* var. *α laciniata*. B. Sub-genus *Ligustrina*: flowers rotate. 8, *S. amurensis*, Mandshuria; 9, *S. pekinensis*, China; 10, *S. japonica*, Japan; 11, *S. rotundifolia*, Mandshuria.

Deutzia crenata in Shrubberies.—This makes a beautiful shrub, and at this season is very useful for furnishing cut

flowers, its pure white blossoms being well adapted for decoration. It also makes a good single specimen on the grass. Some of the old flowering wood should be cut out annually, to allow space for young vigorous shoots that spring from the base, and which produce the finest display of flower.—*J. G.*

THE FLOWER GARDEN.

INSECTIVOROUS PLANTS.

By G. B. CORBIN.

Few, especially those who have visited the New Forest, are unacquainted with the insectivorous properties of the Sundews (*Droseraceæ*), and the tenacity with which the viscous matter exuding from the glandular hairs, with which the leaves are encircled, entraps and holds the unfortunate insect that comes within reach. These are not of the smaller kinds only, but sometimes—as my friend the Rev. H. M. Wilkinson informs me—insects as large as a dragonfly are caught, and their juices assimilated to the plant's well-being; or, again, the Butterwort (*Pinguicula*) acts in a somewhat similar manner; whilst in the water the Bladderwort (*Utricularia*) has an equally wonderful property of entrapping small water-slugs and insects, and, as Mr. Darwin propounds, thrives upon such fare. Certain it is that small creatures are often found inside the bladder-like processes with which the last-named wonderful class of plants are provided; but how much the presence of the insects in such a situation contributes to the plant's well-being I leave for others to judge. In the case of the Sundews it is very evident that the plant absorbs or digests the softer portions of the imprisoned insect, as the dried and rejected skeletons may sometimes be found almost covering the leaves, and the so-called digestive properties of the plant may be proved by placing one insect within its grasp, and killing another insect of the same species and placing it out of reach on some object near. It will be seen that the insect upon the Sundew is skeletonised and sucked dry in a comparatively short space of time, whilst the other dries in the same manner as our cabinet specimens. In the instances above cited the insects seem to have been the unwilling prisoners of the plants retaining them; but other instances have come under my observation where the insects appear to have voluntarily settled upon the plant and died.

A few years ago I saw a plant in the New Forest, some species of Dead Nettle, with many insects attached to its leaves; and last year, in Devonshire, I saw a somewhat similar occurrence, only that the plant was, I believe, akin, to the Mullein. The leaves of the plants in both cases were beset with vegetable hairs, and the insects might have been partially detained by them, but they were as perfect as any in our cabinets. But the most remarkable instance, which induced me to begin this note, came under my observation last July, as follows:—I was strolling in the meadows by a broad ditch where an abundance of plants common to such situations were growing, as Figwort (*Scrophularia*), Hemp Agrimony (*Eupatorium*), Mugwort, (*Artemisia*), &c., and my notice was attracted to the number of flies that were settled upon the last-named plants; and on making a closer inspection I was surprised to find most of the insects were dead. These were attached to the plants in various situations, but in many, if not in all cases, the insect seemed to have settled thereon from choice; some had clasped the points of the leaf, whilst others seemed to hold the smaller stems of the branch in their embrace. Many of the insects were quite perfect, but others were broken from the motion of the plants caused by the wind. At first I thought the smell of the plant had attracted and killed them; but has it ever been proved that this plant is in any way poisonous to insect life? The most remarkable part of this case is that the insects were to be seen only upon the Mugwort, and this only for about 5 yards or 6 yards in extent, whilst other plants growing in the vicinity were free from them. It is true I saw a few scattered individuals upon plants of Mugwort outside this "charmed circle," but within the space above indicated I saw thousands of defunct Diptera and other insects. I picked some portions of the plants, and showed them whilst fresh to Mr. Wilkinson, who, no doubt, can vouch for the correctness of what I describe. It must be understood that the insects I saw had not died from the attack of a fungoid growth such as we sometimes see, but they appeared to be quite fresh, and for the most part perfect. Has any other similar occurrence come under the notice of other readers of the "Entomologist," and if it has, what cause, or combination of causes, was supposed to have led to such an effect? I may mention that the majority of the insects I saw belonged to the yellowish-brown looking creature (*Scatophaga stercoraria*) so commonly found on cow manure, and the like; but this to me was not so very peculiar, since the insect must be as common, or even commoner, than any other in a locality where cattle were continually grazing.—*Entomologist*.

THE FRUIT GARDEN.

THE STRAWBERRY CROP.

THOUGH this has been heavy and the fruit well grown and coloured, it has lacked that rich brisk flavour which is so peculiar to it—a result entirely due to the excessive rains that have aided to produce fruit more than usually succulent, but with a consequent deficiency of quality. Absence of sunshine has not, however, materially affected the colour. It is a fact proved over a dozen times this very cloudy, dull season, that some of the richest coloured fruits gathered have been those from which the foliage entirely excluded the light. Given a kind remarkable for richness of colour, such as Sir Joseph Paxton, or Lucas, or Empress Eugénie, and the colour has been there, even though the fruit was buried amongst leaves and Grass. The prices of Strawberries in the market have been low this season, as far as growers are concerned; but quantity has made the crop a fairly paying one, and there has been less occasion to gather hurriedly, as the weather has been cooler and the fruits have kept longer. This season runners should be produced in abundance, and the crowns formed by the plants for next season should be strong and robust. Thus more perhaps for the Strawberry than for any other fruit the season has been fairly favourable. In most gardens it is the practice to grow several kinds, not only in order to have a lengthened supply of fruit, but also to obtain variety of sort and flavour. All Strawberries in their way are good, but some are better than others: therefore there is wisdom in growing a good number, as the space occupied need not exceed that required for the production of the same quantity of any one variety. Of sorts which I have grown, perhaps the very earliest is La Grosse Sucrée, a free fruiting kind, the colour of which is rather pale, and in shape longish; its flavour is but of medium quality; it is a kind to grow only for the securing of the earliest fruit in the open air. Then comes that universal favourite, Vicomtesse Héricart de Thury, one that is remarkably prolific and early, and which produces first-class fruit as regards colour and flavour, though not so large as is seen on later kinds; it is a grand Strawberry to grow for early crops. Premier is a fine kind, rich in colour, good in quality, and a large cropper. This sort is remarkable for the erect character of its flower-stalks, the bloom being lifted above the foliage, so as to almost hide it when expanded. When in fruit this is also well kept from the ground, and therefore clean. It may well be classed as a first-rate kind for garden purposes. Sir Joseph Paxton is perhaps the most popular of open-air market kinds. It is not only very prolific, but the fruit is large, handsome, of a deep rich colour, and of good flavour. Specially is its colour a recommendation in the market, but it is a good kind for every one. President is one of the best known kinds, and, though less deep in colour than Sir Joseph Paxton, it is nevertheless largely grown for market, especially under glass. It will be long regarded as a first-class kind. Lucas is less known, but nevertheless a grand sort; the foliage is large, of the old Keen's Seedling type, and is shorter in the stalk than most other kinds. It is a very free fruiter, and a late mid-season sort. The fruit is deep crimson-red in colour, roundish, brisk-flavoured, and luscious. It is well deserving of much more extended cultivation than it now receives. Very widely grown is Sir Charles Napier, and by many largely for late pot culture. It is one of the best of travellers, and thus for market work enjoys a good reputation. The fruit is pale red, longish in shape, and sharp in taste. Those who demur to a sweet Strawberry—and tastes differ greatly—will find in Sir C. Napier a Strawberry to their liking. If I were to recommend specially a Strawberry for cottagers it would be Amaten, as it is without exception the most prolific of all others. As a rule, it produces double the crop commonly found on other kinds, and, although it is perhaps too sharp in flavour for the dessert, it is a capital Strawberry to grow for preserving. It is no unusual thing to see a couple pounds of fruit upon a single stool. Dr. Hogg and the Rev. W. F. Radcliffe are well-known representatives of the British Queen strain, producing large richly flavoured fruit, not always well coloured, and as a rule not too freely. These are kinds to be grown where high-class fruit are specially appreciated. Frogmore Late Pine is another of this high-flavoured section, somewhat shy as a fruiter, but producing perhaps the most deliciously flavoured fruit of all. The peculiar old Pine flavour is well exemplified in this sort, and, as it is a late kind, it ought to be in all collections. To the last I have reserved Empress Eugénie, because I wish to commend strongly this kind, not only for common garden culture, but also, if there be such a place, for the wild fruit garden. It is the very best of all kinds to plant down thickly in some out-of-the-way spot where it can grow just as it likes to produce immense quantities of delicious deep red-coloured, medium-sized fruit for the delectation of children and if desired birds. If it were the rule to have some breadths like this in the nooks and wilds that often surround gar-

Funkia Sieboldi.—The Funkias are plants remarkable for their various kinds of variegation and markings. They will grow in any soil, and the cooler it is the better. Many of them have a noble, I may say a tropical appearance, *F. Sieboldi* being, perhaps, the noblest of all. It is just the kind of plant for grouping and massing in parks and similar places. In short it may be said to be a truly regal plant. Most of our fine hardy herbaceous plants are ineffectual, from only being seen dotted about as single specimens. Were the grouping and massing of such plants as the above adopted more generally in our parks and public gardens the result would be much more satisfactory than the filigree work called carpet bedding, which detracts from that boldness and dignity which parks and public gardens should possess. There are numbers of plants such as the above which if looked up and appreciated would render such places independent both of carpet beds and sub-tropical plants.—THOMAS WILLIAMS, *Ormskirk*.

The Shield-leaved Saxifrage (*S. peltata*).—The shield-like form of the leaves of this plant is unique amongst Saxifrages. So distinct is *S. peltata* in this respect that some have referred it to a section under the name *Peltiphyllum*. It grows about a yard high and as much or even more across, and is a remarkably bold and handsome plant. Its leaves, which arise from a very thick and fleshy creeping rootstock, have stout erect stalks, on the apex of which the target-like blade of the leaf attains a foot or more in diameter. The flowers, which are produced in spring a little before the leaves make their appearance, are borne on stalks from 1 ft. to 2 ft. high in loose clusters from 3 in. to 6 in. in diameter. They are individually about ½ in. across, of a white or very pale pink tint. This Saxifrage is a native of California, where it is found

The Shield-leaved Saxifrage.

growing in the neighbourhood and in the beds of quick-running streamlets throughout the Sierra Nevada, from Mariposa to the head waters of the Sacramento. In cultivation it succeeds best in a deep moist border, consisting chiefly of peaty soil. It may be easily propagated by means of division or seeds, which, in some seasons, are produced in abundance. The plant from which the annexed illustration was prepared, is growing in Mr. Wilson's garden at Weybridge, where it has for some years formed a very conspicuous and attractive object. As an instance of its water-loving propensity it may be stated that it is thriving admirably with other aquatic plants on the Wilson Raft, of which a representation has already been given in THE GARDEN.—W. G.

Utilising Dead Tree Stumps.—When a tree in the dressed grounds or shrubberies dies from any cause, a good way of turning it to account is to saw off the small spray-like branches and leave all the forked strong growths; then loosen and enrich the soil at its base and plant Ivy, Honeysuckle or Clematis, training them up until they reach the forked branches, when they will take care of themselves. By this means any one may soon possess large Ivy-clad stumps who might object to its growing on healthy specimens. In shrubberies climbing plants may by this means be turned to good account.—J. G., *Linton*.

Auriculas and Mealy Bug.—I am grieved to see that Mr. Douglas states that many collections have been attacked by mealy bug. Surely Auricula growers will have to "cave in." The woolly aphid is bad enough, but when to that is superadded mealy bug—a most frightful pest in our greenhouses and stoves—their lot is hard indeed.—V.

dens, they might tempt birds to keep to them rather than attack the garden fruit. In any case, to grow a crop for the free use of children and others in the way indicated, Empress Eugénie is the best of all. Laxton's Pioncer comes with a good reputation as a rare kind. If it is worthy of a place amongst the last half-dozen sorts it is good indeed.

A. D.

A PLATE OF PEARS.

WHETHER we consider its delicious flavour, easy culture, and excellent keeping qualities, or its long-continued supply of beautiful fruit, the Pear in its many varieties may justly lay claim to the title of the fruit *par excellence*. To obtain it in perfection, it should be picked from the tree as soon as the fruit has attained its full growth, and just as it begins to turn from green to the ripening condition. When left beyond that period the ripening process goes on in favour of the seeds, and the quality rapidly deteriorates. A Pear ripened on the tree is not fit to be eaten. Even a day or two too long in the summer varieties renders it dry, flat, and insipid. Autumn and winter fruit, after gathering, which it is desired to keep any length of time, is best preserved in barrels or, better, in boxes, containing about a hushel, in a cool or cold, dry place. When desired for use, to ensure its highest perfection, it should be ripened in a dark, dry place in a moderate temperature, and rigidly excluded from the air. Proper thinning on the tree is an essential point in obtaining well-conditioned fruit, and placing it between layers of flannel is a secret in developing colour and flavour that is worth knowing. A Pear should never be eaten warm. Cooled in the refrigerator in summer and eaten at a temperature between warm and cold in winter, it is perfection, and those who have never tasted some of the finer varieties under these conditions have a pleasing lesson to learn. There are Pears and there are Pears. The average consumer, generally speaking, is acquainted with but a few of the commoner varieties to the exclusion of the really fine sorts. The Seckel, Bartlett, Lawrence, Howell, Flemish Beauty, Belle Luerative, Sheldon, Duchesse, and Beurré d'Anjou, are perhaps the best known and most saleable market varieties. These, at least the majority of those mentioned, are but the lower grades of this really delicious fruit, and no more compare with many of the finer sorts than a Crab or a Gilliflower Apple does to a Spitzenburg or Northern Spy. The Seckel and Bartlett both have a pronounced musky flavour. They suit the average American taste because they are sweet and strongly flavoured. Their popularity, as that of most of the above sorts enumerated, is also, no doubt, largely owing to the fact that only comparatively few are acquainted with the better kinds, and are, therefore, unable to establish a comparison. While many really excellent varieties have originated in this country, the French and the Belgians must be credited with the majority of the really superior kinds.

Summer Varieties.

Beginning with the summer sorts that rank high in the gamut of taste, the Petite Marguerite, recently introduced in France, is especially deserving the attention of the amateur. Its juicy and vinous flesh and delicate *bouquet*, all entitle it to a place in the well-regulated private orchard. It is not large, a trifle larger than the Seckel, but large enough, according to the writer's taste, for a dessert Pear. Of the larger summer Pears, the Clapp's favourite, originated in this country, and a cross between the Bartlett, an English variety, and the Flemish Beauty, a Belgian sort, should not be overlooked. It is entirely free from the muskiness of its English parent, and, considering its size and other really fine qualities, one might look much farther and fare worse. It is said to rot at the core too quickly. This is obviated to a great extent by early gathering. Of the many other summer sorts, the handsome red-cheeked Beurré Giffard, the Rostiezer, a vinous, high-flavoured sort, comparatively a stranger to American collections, and last, but not least, the Tyson, which is much better known, bring up the rank and file among the very early Pears. With the change from the hot summer weather to the mellow and cooler days of autumn, we at once note a difference for the better in the quality of the fruit, which seems to become imbued with the vinous richness of Nature's harvest season, autumn sorts having more character, piquancy, and flavour. Of this class it is an extremely difficult matter to choose between several varieties. Whoever has been fortunate enough to taste a Beurré Superfin, fully matured, ripened to a nicety, and glistening in its bright, smooth, oily skin, need look no farther for the acme of perfection in the Pear. It is as juicy as a Peach, and fully merits its appellation "superfine." Like many good things it will not keep long.

Autumn Sorts.

Among autumn Pears, the Urbaniste, a Belgian sort, is second to none. It is one of the acidulous kinds, like the Superfin, of good size, melting, very juicy, and of most exquisite flavour and perfume,

strongly resembling attar of Roses. This particular aroma is always very pronounced. The *bouquet* has been described as the "soul" of wine, and this characteristic odour in the Urbaniste is one of its chief attractions. The aroma which gives the character of the fruit in many varieties of Pears lies just below the skin as in the case of the Urbaniste; in others it is contained in the entire juices of the fruit. If the Urbaniste and Beurré Superfin are entitled to a top-most place, Gansel's Bergamot, an old English variety, certainly deserves equal prominence. It is a profuse bearer, a medium-sized Apple-shaped, russety fruit, melting, and of a most rich and sprightly sub-acid flavour. It is to autumn Pears what the juicy and highly-flavoured Gravenstein is to the autumn varieties of Apples. Being difficult to grow it rarely finds its way even to private tables and is unknown in market. Poor growing sorts like Gansel's Bergamot are rendered tractable by being re-grafted, or, as it is termed in nursery parlance, "double worked," on strong growers. Sorts like the Gansel's are worthy of any trouble to obtain. The Louise Bonne of Jersey is an acidulous Pear, tolerably well known in this country, that never fails to please a person of that taste, carrying its tartness as far as possible without absolute excess. But its good qualities are sadly counterbalanced in this climate by its apparent tendency to blight. The Louise Bonne is recommended by its vigorous and handsome growth of tree and its productiveness. The fruit is elegant in form, beautifully coloured, the flesh melting and overflowing with refreshing vinous juice. Nevertheless, in point of quality, it does not reach the very high flavour mark of the Gansel's Bergamot, Urbaniste, or Beurré Superfin. A well known Pear is the White Doyenné or Virgalieu of the French. It is without doubt the handsomest coloured Pear grown, being as rosy-cheeked as a Lady Apple. Of late years the fruit has cracked badly with us. The White Doyenné is distinguished by a certain perfume possessed by no other variety. Although regarded as adapted to most every one's taste, it is lacking in the vinosity which to a trained palate is generally considered one of the essential virtues of the really superior sorts. The Sheldon, a large round, golden-russet fruit of Western New York origin, previously referred to as among the best known varieties in this country, when well grown and well ripened, is usually regarded as deserving a place among table fruits of the first order of merit. It is a general favourite with those who are partial to the honeyed sorts. Like some others it has a slight suspicion of muskiness, and, as reviewed from our individual point of taste, lacks the "snap" that is essential to complete the harmony of a perfect Pear. The Seckel, a household word amongst American fruits, is too well known to need description. Its honeyed sweetness and its marked flavour, recalling that of Mosel-Muscatel, are usually objected to by connoisseurs, although it finds favour with so high a pomological authority as Mr. Thomas. Dana's Hovey, one of the vinous sorts, which has recently made its bow to the pomological public, is highly extolled in Massachusetts, where it originated. It has been little fruited in this vicinity, and we are personally unacquainted with it except by favourable reputation. The Duchesse, a deservedly esteemed market sort, would be of great value for the private orchard, were it not that there are so many other superior kinds to choose from. Nevertheless, its great size, splendid golden colour, and good qualities, will always entitle it to be called a noble fruit. Not to mention the Bonne du Puits-Ansault, a comparatively new French variety among the autumn Pears, would be a glaring oversight. One needs but to have once tasted its delicious, melting, and sprightly sub-acid flesh to accord it a foremost place in the galaxy of *ne plus ultra* Pears. The amateur cannot afford to do without it. This variety does best as a standard. Dr. Reeder, a recently-introduced Pear, originated by that gentleman at Varick, and disseminated by Ellwanger & Barry, is one of those good things that come done up in small packages. With its small, roundish, ovate form and bright golden skin, netted and sprinkled with russet, combined with its exquisite, fine, juicy, and vinous flesh, it has scarcely a superior as a dessert fruit. For the amateur it is a veritable treasure trove. Of the claims of the Beurré Bose to pre-eminence as a table fruit, we do not agree with even so eminent an authority as Mr. Downing, who is particularly partial to this handsome representative of the Calabasse type. It is high-flavoured and delicious, but is rather lacking in juice, and it does not possess that acidulousness to which we have previously referred as one of the great desiderata. It is, however, the *beau idéal* of shapeliness. The Beurré Bose, in particular, requires to be very ripe to call forth its good qualities.

Winter Pears.

We now come to the winter varieties, of which the Beurré d'Anjou is, perhaps, the most popular. This is a variety, all things considered, that we cannot do without; its size, flavour, and excellent keeping qualities, all render it worthy of a foremost place in the catalogue of desirable fruits. Among the winter sorts "of name and noble estimate" is Winter Nelis, a

favourite Belgian sort, that makes up in quality what it may lack in form and general appearance. It has a great deal of individuality, its melting, buttery flesh being characterised by a certain spicy, nutty aroma, peculiarly its own. It always comes into admirable play as a winter table fruit. Those who regret the poor keeping qualities of the Superfin can console themselves later in the season with the Easter Beurré, which is of a similar piquant flavour. In keeping qualities it has no superior. In France, and in this country among careful growers, it attains a very large size. Its good qualities as a fruit are offset in a measure by its slow habit of growth, its tendency to blight, and its only thriving in the best of soil and under careful treatment. In spite of these objections, it is a *sine qua non* among winter sorts, and to every really choice Pear garden. Easter Beurré is best cultivated on the Quince. Last but not least among the desirable varieties for the amateur is the Josephine de Malines, without doubt the most valuable late-keeping Pear. For this great acquisition we have also to thank the Belgians. Its skin is of a pale yellow, and its flesh a light salmon colour, and of a most delightful rose flavour, similar to but not so pronounced as the Urbaniste. Of comparatively recent introduction into this country, it is scarcely known in market, but is prized beyond measure by those who are acquainted with it. The Josephine succeeds both as a dwarf and a standard. There are many other excellent sorts that, if not fully equal to those enumerated, are still eminently deserving of notice. Tastes differ in fruits as in wines. But there is an acknowledged standard of excellence in both that meets the general taste. Judging from this standpoint, the varieties referred to above as possessing the cardinal virtues comprise the very best among the table sorts, and are amply sufficient for an abundant variety in the largest and most carefully selected orchard. Except where otherwise noted, all are suitable for cultivation as dwarfs. Our remarks are confined to private gardens only, where quality is desired, even if it be largely at the expense of quantity. But in a well-cared-for fruit-garden, with proper treatment, the poorest bearers may be made, if not to "blossom as the Rose," to "give forth their fruit in due season" in comparative abundance.

Summing Up.

To sum up, with the Petite Marguerite, Favourite, Rostiezer, Beurré Giffard, and Tyson, of the summer sorts; the Beurré Superfin, Urbaniste, Gansel's Bergamot, Bonne du Puits-Ansault, Dr. Reeder, and Louise Bonne among the autumn varieties; and the Beurré d'Anjou, Winter Nelis, Easter Beurré, and the Josephine among the winter sorts, the amateur can revel in a succession of the finest of fruit from early summer till early spring. In conclusion, it may be interesting to know the individual tastes of the six leading American pomologists of the day as to table Pears, quality of the fruit alone being taken into consideration. Mr. Barry says—"Whenever I taste a Gansel's Bergamot, ripened to perfection, I always come to the conclusion it is the best Pear, as far as quality is concerned." Marshall P. Wilder remarks—"If pinned to one for quality, I must, considering all things, say Anjou, which I have on the table every morning for over four months in the year." Mr. George Ellwanger states that "for absolute perfection for table use, I name the Beurré Superfin." Mr. Charles Downing—"If I were limited to one Pear, it would be Beurré Bosc." Mr. J. J. Thomas—"For uniform excellence every year, without variation, the Seckel is undoubtedly the finest in quality. There are some others, as the Belle Lucrative, Grey Doyenné, &c., that are sometimes very fine and unexcelled." And finally, Mr. C. M. Hovey says—"If I were to name the very best Pear, without regard to season, I should name Dana's Hovey as the *ne plus ultra* of flavour and exquisiteness, and all other qualities except size."

When doctors disagree, who shall decide?—H. ELLWANGER, in *Country Gentleman*.

Strawberries for Light Soil.—At this season many plant their main crops of Strawberries in the open ground, and, owing to there being so many sorts from which to select, some may be glad to know which are the best to plant. Most people will agree with me in thinking that Strawberries, like other fruits, are affected by soil, locality, and situation. Some sorts, good in every way in one place, are worthless in another. I will name an instance in point: Some years ago, when in Dorset, Dr. Hogg proved itself to be a good Strawberry, but here in North Hants it does not succeed. James Veitch is much the same; some like this Strawberry, but I think we have many better. Here on light soil—by no means a good Strawberry soil—the following sorts do best, viz., Keen's Seedling, Sir C. Napier, President, and, last but not least, Oscar; I grow this as my main crop; it yields much more largely than any other, and the fruit is excellent. To those who, like me, have not a good soil for Strawberries, I would say give this sort a trial.—J. C. F.

OUTDOOR VINE CULTURE.

As this subject has again cropped up, it may perhaps not be out of place to quote a few lines from "Forsyth's Treatise on the Culture and Management of Fruit Trees," published in 1803, Mr. Forsyth being then gardener to his Majesty George III. at Kensington and St. James's Palaces. At p. 195 he writes: "I have had very fine Grapes on east and west walls in good seasons, between Peaches, Plums, &c., particularly when the trees were young. I also train them over the tops of trees on each side, which never does any harm to the trees below provided you keep them nailed to the wall. I have also planted Vines between trees on north and east aspects, and trained them over the tops of the south and west walls to fill up the upper parts till the Peaches and Nectarines covered them. Two years ago I removed some old Apricots that covered a wall 165 ft. long, leaving five Vines that were planted against the piers. These five Vines have in the course of two years covered the above wall from top to bottom, and bear plenty of fine Grapes every year. I also moved an old Vine on a wall near to the above and cut it in pretty closely; it has in three years spread 26 yards, and bears very fine fruit. Against one of the piers had been planted a Black Hamburg Grape, and the other side of the same pier was planted a Muscadine, at the distance of 2 ft. from each other. I pruned them according to my method, and the second year afterwards they produced 1100 bunches of fine Grapes."

In another chapter he describes his method of training Vines as follows. "When I took them in hand the fruit was so small and hard as to render it unfit to be sent to table. The Vines were trained upright, which caused them to grow so luxuriantly that the sap flowed into the branches instead of the fruit. In the year 1789 I let two strong branches grow to their full length without topping them during the summer. In 1790 I trained them in a serpentine form, leaving about thirty eyes on each shoot, which produced 125 bunches of Grapes, weighing from 1 lb. to 1½ lb. each. Every one who saw them said that they were as fine as forced Grapes. More fully to prove the success of this experiment, I next year trained five plants in the same way, and they were as productive as those in the former year. After a three years' trial I thought I was warranted to follow the same practice with the whole; and in the year 1793 I sent, for the use of his Majesty and the Royal Family, 378 baskets of Grapes each weighing about 3 lb."

From these extracts it seems pretty certain that good Grapes could be grown out-of-doors ninety years ago, and that being the case, I would ask, "Why cannot the same thing be done now?" We sometimes hear of the seasons being changed; but is that really so? A few remarks on the weather are quoted in the book just referred to, from which I cannot learn that it was any better then than that which we generally experience now, for he says that 1799 was a very wet and cold season, while 1800 was a very hot and dry one. In another place he mentions "cold blighting winds and frosty nights, such as we have had for several years past in June and July, cause young Pears to canker and fall off."

There can be no doubt that good Grapes might be cultivated in this country out-of-doors in favourable localities, especially on good south walls, which might also have the advantage of glass protectors, such as are used for Peaches and Nectarines. The chief points to be attended to would be a well-made and well-drained border to commence with; then a clean healthy growth, trained very thinly on the walls, so as to get it well ripened in the autumn; and the next season the usual routine of disbudbing, stopping, thinning, &c., such as is generally practised in houses. With such attentions the result would be, I believe, very good Grapes, not, of course, to be compared with our finest hothouse produce, but such as would be highly appreciated by the million, who would gladly purchase them could they be offered to them at reasonable rates. H. HARRIS.

Denne Park.

ORDINARY FRUITS SENT OUT AS MARVELS.

EVERY year the public is disappointed in regard to some new fruit, of which we are led to expect wonderful things, from the unstinted praise and unlimited claims with which it is started off on its brief career. As a rule, we do not think that this fact results from any wish or effort to impose on the public poor or second-rate varieties, but rather from a defective acquaintance with the kinds already in cultivation. A person who cultivates but comparatively few varieties, may find a seedling, or possibly a good old variety, that he has never seen and perhaps never heard of, and he is greatly struck with its merits. He takes it up, puts it in a favourable place, and gives it extra care. The old varieties may even be neglected in the enthusiasm for the plausible stranger. Of course the highly-petted plants respond. I can take the Highland Hardy Raspberry, or Wilson Strawberry, and,

by a course of high culture, make them astonish the natives, and seem to the uninitiated like new varieties.

Neighbours and friends are called in to see the prodigy. They in most cases have had even less experience than the originator or discoverer, and they very honestly say that they have never seen anything so fine. Thus hopes and reputation grow apace. By and by the petted plant is sent, with a great flourish of trumpets, out into the rough and tumble of the world, and is compelled to endure any amount of what a friend of mine terms "wholesome neglect." It is also placed side by side with the great standard varieties that made their reputation years ago. After one year's fruiting the sanguine purchaser shrugs his shoulders over the new comer. After the second year he may wrathfully dig it out, saying that "the best kinds are good enough for him, and that he has no land or time for third-rate sorts." Or he may find that the new seedling, of which he expected so much, so closely resembles some variety that he already has, that he cannot tell them apart. As a case in point, I could never distinguish between the Romeyn Seedling Strawberry and the Triomphe de Gand. In Raspberries, I fear we are about to have a still more marked example. Good judges thought the Amazon identical with the Belle de Fontenay, and now truth compels me to say that on my place the Henrietta so nearly resembles the Belle de Fontenay, that I cannot tell them apart. I do not say that it is not a new seedling, but its parentage is very plain, and if grown side by side, I think it will be difficult to distinguish the two.

From the nature of things, we must always expect these disappointments. It may seem a harsh and ungracious task to blight with criticism the prospects of some new and greatly praised variety, and yet it is clearly one's duty to state plain unvarnished truth about these claimants to popular favour. A wide acquaintance with the fruits already in cultivation is perhaps the best preventive of the evil referred to. If a man knows well the characteristics of fruits already before the public, he will not send out varieties so inferior to, or so closely resembling them, that no advantage is gained. Last spring I started a specimen Strawberry bed. It contained fifty rows, and each row is a different variety, labelled in large letters. Anyone can walk down this bed and compare the foliage, fruit, and general merit of all these kinds at a glance. They are all grown under precisely the same conditions, no more favour being shown to one variety than to another. By another year I expect to have a hundred or more varieties growing side by side. It is my intention to start this autumn similar specimen beds of Raspberries, and all the other small fruits. Everything new that comes out will have to pass the ordeal of growing side by side with all the varieties that are not utterly obsolete. Then if it ranks with the best, or above them all, it is entitled to wear a crown.—*American Agriculturist*.

Heavy Crops of Peaches and Nectarines.—I send you an example of our Nectarines as seen growing. 23 dozen (see p. 136) is not a tithe of a crop on a large tree. I regret, however, to say that I made a mistake in my previous statement; the large Peach tree covers a space of 484 sq. ft., and at the average of ten fruit to a sq. ft. as given before, and which can be verified by others, the tree has this season carried over 400 dozen instead of 330 as stated (p. 105).—T. COWBURN. [The shoot sent showed five good-sized well-ripened Nectarines all growing within a space of 6 in.—three on one side of the shoot and two on the other. They were stated to be the remnant of a crop from which daily gatherings have been made for more than three weeks.]

— Allow me to inform "R. H." that Mr. Cowburn has underrated rather than overrated his Peach crop. It has been proved that one tree bore over 400 dozen fruit instead of 330 dozen, as stated (p. 105) by Mr. Cowburn.—J. FANCOURT, *The Nurseries, Fulham*.

— I was at Sunbury Park on the 1st inst., and saw Mr. Cowburn's Peaches and Nectarines, and can vouch for the correctness of his statement. I never before saw such a crop of fine Peaches on one tree. His Nectarines, too, were equally good.—THOMAS LANCASTER.

The Pacific Rural Hand-book, by Charles H. Shinn; published by Dewey & Co., San Francisco, California.—This contains a series of essays on tree culture, vegetable and flower gardening on the Pacific coast. The author is well known as a practical horticulturist, and a work especially adapted to their peculiar climate must be welcome to all cultivators upon the Pacific coast. Mr. Shinn, as our own columns indeed testify, writes well and gracefully on horticultural matters. He is the editor of the *California Horticulturist*, which has lately been a production of remarkable merit considering it is published in a country where a year or two before the first great London exhibition there were no gardens and very few houses.

NOTES OF THE WEEK.

New Hybrid Gladiolus (*G. hybridus Lemoineanus*).—This fine hybrid Gladiolus, raised by M. Lemoine, of Nancy, is the result of a cross between *G. purpureo-auratus*, a true species and a native of Natal, and *G. gandavensis*, which is itself a hybrid, and one of those from which the many varieties grown in gardens have emanated, having been raised some years ago between *G. psittacinus* and *G. cardinalis*. Lemoine's Gladiolus, which grows from 2 ft. to 3 ft. high, partakes in a striking degree of the characters of both parents, but it is said to have the more perennial character of *G. purpureo-auratus*. It is of robust growth, with plaited foliage of a rich green colour. Its flowers, which are about the size of those of ordinary garden Gladioli, are arranged closely on the spike, which is about 1 ft. long. The three upper segments, which are broad, are of a creamy white colour, and the lowermost one has a thick streak of rich deep purplish-crimson down the centre; the other two are wholly that colour except about $\frac{1}{2}$ in. at the tips, which is a bright yellow. It is now in flower in the open border in Messrs. Veitch & Son's Nursery at Chelsea, whence it was exhibited at South Kensington on Tuesday last, and was deservedly awarded a first-class certificate.

Mutisia decurrens.—A plant of this charming Chilean Composite is now in flower against a wall in the herbaceous ground at Kew, and is the admiration of every one who sees it, though the recent storm has considerably impaired its beauty. It is apparently in vigorous health, and the position seems to suit it admirably. The exposure is due south, and it is planted in a compost of good fibry loam and leaf-mould. The principal point, however, requiring attention is to keep the plant dry during the winter months.

Conandron ramondioides.—This interesting little plant was recently introduced from Japan by Messrs. Veitch & Sons. As its specific name implies, it is similar to a *Ramondia*, and, indeed, remarkably like *R. pyrenaica*. Its thick, fleshy, oblong, green leaves, from 4 in. to 5 in. long, form a tuft from which arise the flower-stems, about 6 in. high. These are erect and much branched, the upper half bearing several flowers, which measure nearly 1 in. across, and which have five points that slightly reflex. In colour they are a rich lilac-purple, the centre being chocolate and the stamens yellow.

Lilium testaceum.—By far the finest examples of this superb Lily which we have seen this season were growing in the herbaceous borders at Petworth Park. They were planted near a wall running east and west, so that they would be shaded during the hottest part of the day. The soil in which they were growing was rich and light, conditions which evidently suited them. Near these was a bed of *L. auratum*, consisting of well-grown plants finely in bloom. These were planted in similar soil in a corner sheltered from north and east winds.

Acacia Riceana.—This is one of the most desirable of all Acacias for greenhouse decoration, on account of the graceful pendulous habit of its slender branches, which are furnished with needle-like leaves and small balls of pale yellow, feathery blossoms. It is a plant that is easily cultivated, and one which will thrive admirably in any well-ventilated greenhouse. It is a native of Tasmania, where it grows abundantly on the banks of the river Derwent, and forms a beautiful feature during the flowering season. It is one of the most charming plants in the conservatory at Petworth.

Solanum crispum.—When seen in the form of large specimens, this, when in flower, is one of the most ornamental of shrubs. We lately saw in a garden in Sussex a specimen of it fully 15 ft. high, with a large round head of branches covered with clusters of rich purple Potato-like blossoms. As to its hardiness there can be no doubt, as the specimen in question has been planted many years, and withstood even the past severe winter unscathed, though quite unprotected. It is a native of Chili, and one of the oldest introductions to our shrubberies.

Genista ætnensis.—Though by no means uncommon, this is a very desirable late-flowering shrub. At Kew, where it is now very conspicuous, plants of it may be seen varying from 3 ft. to 8 ft. high, and bearing abundance of small flowers, forming a mass of yellow, which stands out in bold relief from the deep green foliage of other occupants of the shrubberies.

Seedling Begonias.—We have received from Messrs. Sutton & Sons, of Reading, beautiful blooms of tuberous-rooted Begonias, both double and single, raised from seed obtained from a select strain. The flowers of most of them are large, well-formed, and brilliant in colour. *B. boliviensis*, Veitchi, Davisi, and the yellow-flowered *B. Piercei* are apparently the principal parents of these tuberous Begonias, and it is remarkable how in some forms the several characters of these sorts are combined; for instance the free-flowering tendency of *B. boliviensis* and the sturdy habit of *B. Veitchi* are seen in some, whilst in others the beautifully-mottled foliage of *B. Piercei*

is traceable even in the case of such as have scarlet blossoms. The rich deep crimson of *B. Davisii*, too, is apparent in several of the seedlings from it, but their flowers are scarcely so large as those of the others. The double flowers represent in some cases perfect cones of brilliant colour. These examples fully bear out the remark made some time ago in THE GARDEN that these popular flowers would eventually be obtained from seed from carefully-selected strains, as in the case of *Cinerarias*, *Calceolarias*, and other showy greenhouse plants.

Chirita sinensis.—The prettily variegated leaves of this plant, added to the delicate mauve-tinted and yellow-spotted blossoms which are produced abundantly, place it amongst the most desirable of plants for the decoration of a moderately warm greenhouse. It is easily cultivated, and continues in beauty for a considerable time. We saw it a few days ago in fine condition in one of the houses at the Pine-apple Nursery, growing in company with other Gesneraceous plants, a family to which it belongs.

Impatiens Jerdoniæ.—This is one of the brightest little plants at the present time in the Stoves of Messrs. Henderson's nursery, Maida Vale, where it is grown in considerable quantity. Unlike the majority of other Balsams it is of dwarf compact habit, growing not more than about 6 in. high. The leaves are tufted on the fleshy branches, and have a dark bronzy lustre on their surface which contrasts beautifully with the bright scarlet and yellow horn-like blossoms, that are borne in profusion for a succession of weeks during summer. Although it may be easily grown as an ordinary pot plant, it is admirably adapted for growing suspended in baskets, a mode of culture which shows its beauty off to advantage, but under either method of culture it is a very ornamental plant.

Galphimia glauca.—This Mexican shrub is seldom met with, but as shown at the last meeting at South Kensington it forms a handsome bush which would be well worth growing for general decorative purposes. The leaves are rather small and elliptic in shape, and covered with a glaucous hue, which gives the plant an unusual appearance. The flowers, which are yellow, are about the size of a sixpenny piece, and are borne in racemes springing from the axils of the leaves. It is a member of the Barbadoes Cherry family (*Malpighiaceæ*), and is doubtless as amenable to culture as its congener.

The Chinese Privet (*Ligustrum sinense*).—One of the most conspicuous shrubs now in flower at Kew is this excellent Privet. It varies in height from 3 ft. to 7 ft., and the slender branches furnished with wavy, yellowish-green leaves, curve gracefully outwards. The flowers, which are white, small, and starlike, are borne in dense panicles, and their fragrance is almost overpowering. These are succeeded by shot-like, purple berries, which, in autumn, are also very ornamental. It is one of Mr. Fortune's numerous introductions from China. Being perfectly hardy and nearly evergreen, it is an excellent shrub for any garden, whether large or small.

Evening Primroses Indoors.—These are somewhat unusual plants for conservatory decoration, but they answer admirably for that purpose, and have a pretty effect when, towards evening, they expand their bright yellow blossoms. Their sweet perfume, too, is another point in their favour. They are largely used to adorn the conservatory at Goodwood. The biennial kind (*Eurotia biennis*) is that principally used.

The Gentian-like Grammanthes (†, *gentianoides*).—This, one of the prettiest Alpines now in flower at Kew, is a capital plant for growing on dry parts of a rockery, or, indeed, in any other exposed situation. It grows about 2 in. high, and forms a dense, much branched tuft with fleshy leaves about $\frac{1}{2}$ in. long. It produces flowers in abundance; they have pointed petals, and measure about two thirds of an inch across. Their colour, when first expanded, is orange, with a distinct V-shaped mark at the base of each petal, but they finally assume a deep red hue. It belongs to the Stonecrop family; it is a native of the Cape of Good Hope, and was introduced into this country towards the end of the last century, but, nevertheless, it is even now far from being so widely known as it should be.

Royal Gift.—A park of 20 acres, the gift of the Queen, has just been opened at Heywood, near Manchester. In 1873, Mr. Charles Newhouse, a wealthy inhabitant of that town, was killed through a railway accident. He died intestate, and the Queen, as Duchess of Lancaster, accordingly came into possession of his estate. Her Majesty intimated her wish to present the estate to the town, and after some deliberation it was resolved that the gift should take the form of a public park. This has now been done, due provision being made for those who had claims upon the estate. The park has cost about £11,000.

Hampstead Heath.—Since this heath has been under the Metropolitan Board of Works it has been much improved. Planting has been successfully begun and the Ferns and other wild plants have

been protected; but much remains to be done before it can be considered at all creditable to the Board. The old roads are well kept, but new roads are wanted. These should be as well made as they are on Clapham Common or Blackheath, and should be planted as avenues; and much more might be done to make this beautiful and healthy spot more useful and more ornamental without at all interfering with its natural undulations or its almost wild characteristics.

MIDDLEHEATH COTTAGE GARDEN, CROYDON

This garden furnishes an admirable example as to how a comparatively small space of ground may be utilised economically and yet afford the luxuries derived from gardens of larger dimensions; the glass structures, indeed, are built upon a plan so simple and inexpensive that they are within the reach of all who own a garden and who would like a greenhouse too. They are arranged so as to form a continuous circuit round the garden, and thus, apart from their utility, they form a delightful promenade during winter without having to go into the open air. Attached to the dwelling-house is a conservatory, the roof of which is of wood and curvilinear, though glazed with flat glass. In a raised portion of the roof are placed Argand gas-burners surrounded by four-sided mirrors; these, owing to their height and other arrangements for carrying off heated air, are perfectly harmless to the plants beneath, and when lighted have a beautiful effect. The walls are rendered rustic in appearance by means of cork and other material; and the plants, too, are disposed naturally, without formal stages or exposing too much of the pots, which often mar the effect produced by beautiful plants in houses. Ferns of various kinds are used, as well as ornamental-leaved Begonias, Palms, Orchids, and Marantas, amongst which a fine example of *M. Veitchii* was noteworthy. A stream of water trickling from the eaves of a tastefully-constructed rockery, and falling into a pool below, in which are fishes and water-plants, adds considerable interest to the place. Climbing plants cover the roof, and from it are suspended baskets of Ferns, which have an elegant appearance; amongst these a handsome plant of the delicate *Adiantum gracillimum* shows how admirably adapted it is for such positions. Following a flight of rustic steps is a house 8 ft. wide and 250 ft. long devoted entirely to plants requiring similar treatment; trained to the back wall are Fuchsias and Camellias planted alternately, and they also flower alternately, for as soon as the flowering season of the Camellias is over the Fuchsias begin and continue until the Camellias flower again; both comprise the finest varieties and their full beauty is well shown, as they obtain an abundance of light and ventilation. Besides these there are hosts of climbing and other plants, such as Lapagerias, Clematises, Tea Roses, Heliotropes, &c., all hanging in graceful profusion from the roof and side walls. *Clerodendron Thomsona*, too, succeeds admirably along with these greenhouse subjects, and is now covered with blossom. Ferns, both hardy and greenhouse kinds, luxuriate along the sides of the path, and the whole is carpeted with *Selaginella Kraussiana*. A couple of 4-in. hot-water pipes are found sufficient to keep this house at an agreeable temperature in winter, and to effectually keep out frost. The next house, a wider one, which is kept at a higher temperature, is devoted to stove plants; in this house, too, was a thriving selection of Orchids, and growing on the same shelves some singular-looking *Stapelias* were producing their quaintly-spotted flowers, thus affording a striking instance of moisture-loving plants and those from arid regions accommodating themselves under the same conditions.

Some substantially built Vineries came next under notice, from one of which the crop had been cut. A succession Vinery, which contained several distinct varieties of Grapes, also contained a Peach tree growing against the back wall, and bearing a good crop of fruit; while on the ends of the house was a fine crop of Tomatoes, and the centre was filled with plants such as Coleuses, &c., thus affording an example of how much can be effected even with one house. Another house, over 100 ft. long, is devoted entirely to Peach and Nectarine trees, all of which are bearing heavy crops. This house is divided into two compartments, one for early forced fruit, the other for fruit to come on in succession. The mode of construction corresponds with that in the long house, except that in this there is no brick wall against which to build. Mr. Lascelles, however, has erected a substitute, which though not so substantial is quite as efficient, and far less costly. The house in question is about 8 ft. wide, and at intervals of about 7 ft. are built boxes of concrete, in which the trees are planted. These are 3 ft. long, 2 ft. wide, and 2 ft. deep, and before planting these require about 6 in. of rubble being put at the bottom for drainage, and a hole for the escape of water. On the edges of these boxes is placed the sill into which the uprights are fixed at intervals of about 1½ ft. The uprights consist of ordinary sash bars, which fit into a ridge plate at the top. Outside the sash-bars are ordinary roofing slates, fixed with putty and nails in the same way as glass would be

fixed in sashes, thus enclosing all woodwork which in the ordinary way would be exposed to the action of the weather, and thereby rendered more liable to decay. This completes the back wall, which is about 8 ft. high. The front of the house is constructed in a similar way, except that instead of slates there is glass fixed between the sash-bars, with a row of upright slates at the bottom fixed in the soil. The ventilation is effected by a simple contrivance, by means of which the roof and front lights are moved. The trees are not trained close to the back wall or the front lights, but are brought forward and tied to a galvanised wire trellis, at about 1 ft. from the back and front. As the trees are grown somewhat according to the system of pot culture, their growth is considerably restricted, and they make short well-ripened spurs which are very productive, and though the back wall has a northern aspect, the heat which passes through the thin slates on the southern side is sufficient to mature the fruit both in colour and flavour equal to that produced on the opposite side. In the intervening partition boxes in which the Peach and Nectarine trees are planted inside are grown Cherries and Plums, which are trained to the outside wall, which, having a southerly aspect, produces an early crop of these fruits.

These houses have been erected for over six years, and still they look none the worse, on account of the small amount of woodwork exposed. Another desirable point obtainable by this system is that no matter what the nature of the surrounding soil may be it does not affect the fruit trees, as the roots are quite enclosed, and the comparatively small amount of soil required to fill the boxes can be made to consist of the best and most suitable material, and an occasional top-dressing of some concentrated manure is all that is afterwards required. It should have been previously mentioned that the wall-sill at the bottom is placed on the centre of the concrete boxes, so that half the boxes are inside the house, and half outside, an arrangement by which the soil in the boxes is kept sufficiently moist during the greater part of the year by the rain that drains from the roof. Another feature in this garden is the rocky banks made of concrete, which are planted with Strawberry and other hardy plants, and which have a pretty effect, as they grow rapidly and hang over the ledges.

W. G.

THE GOLD DIGGER'S BUTTON-HOLE.

THE mining camp of Mabie was shut in by forest-covered heights, and shadowy mountains, and royal, shining peaks of snow; translucent, ethereal, tremulous with the awakening rose of morning and the fading hues of sunset. From under those far peaks an icy river crept, and wandering south for many miles met another similar stream flowing northward, and they flowed on together to the ocean. The busy little town was clustered about the point where these rivers united; and a dusty road, winding down the hillside, crossed the black rough-hewn bridge, and slowly passed out of sight. This road was the only connection with the outer world; the great hulks of the freight-waggons rose and fell over hummock and rut; the light mail-waggon passed; the mule-mounted prospector trotted by; and, at some rare intervals, a footsore, impecunious wayfarer rested his weary limbs in the pleasant little town.

There was a white cottage by the roadside just at the entrance to Mabie. Garden there was none, for the soil had been sluiced off down to bed-rock, but an Oleander bush grew and flourished in a large box by the door. A little girl stood by it tiptoeing up to smell the gorgeous masses of bloom. Just then a footsore miner, evidently tired, hungry, and discouraged, came slowly along the road, weighted by a roll of blankets. He was, in simple truth, an unkempt, ragged, rather truculent looking miner, and seeing the little girl and the blooming Oleander, he stopped by the gate and looked in.

"Little girl," he said in a low tone, "them's purty flowers; could ye give me one?"

The child looked at him half afraid, but she summoned up courage at last, and breaking off a cluster which drooped temptingly near, held it half doubtfully a moment, and then tripping shyly down the broken steps placed it in his hands. She hardly waited to be sure he held it before she fled back to her vantage ground, and sitting on the step of the porch, poised her chin on her hand, looking coquettishly up at the brown, bearded miner. There was a long pause, and silence. The miner laid his cluster of flowers on the fence rail, and fumbled uneasily with the buckle of his heavy pack, from which the flat handle of a frying-pan protruded. The little girl watched him curiously. He unstrapped his bundle, gave it a kick, and tore it apart. From the very middle he took a yeast powder can, wrapped about with cloth and tied up with a buckskin thong. A smile spread slowly, and with considerable difficulty, over his face as he shook it and heard a faint rattle.

"Come, little girl," he said, looking up toward where she sat, "come down an' see me a minnit."

She looked shyly down, in a wavering attitude, hardly knowing

whether to cry or smile, but curiosity won, and the chubby child began to climb down the rickety steps, until she stood by the fence, and peeped through between the boards. By this time the miner had opened the yeast powder can, which contained a handful of gold dust and a few nuggets. He chose the largest, an irregular bit, worth perhaps twelve or fifteen dollars, and gave it to the blue-eyed child.

"It's my turn now," he said, "that's for your weddin' day, little girl. Jes' ye tell the folks as how an old prospector came along an' wanted a flower to put in his button-hole."—*California Horiculturist*.

PLATE CXCIII.

MACKAYA BELLA.

Drawn by CONSTANCE PIERREPONT.

THIS beautiful shrub is a native of Natal, and was discovered by Mr. J. Sanderson in 1859 growing in the bed of a stream at Kruis Fontein, Tongat. Subsequently both he and Mr. McKen sent living plants of it to Kew, where it first produced blossoms in 1869. From Mr. Sanderson's original notes accompanying his dried specimens in the Kew Herbarium, and the different plates of *Mackaya bella* that have been published, there appears to be considerable variation in the coloration of the flowers. Probably the greater or lesser intensity of the colour is due to the degree of light to which the plant is exposed. Mr. Sanderson describes the flowers as of a delicate lilac blue in his note in the Kew Herbarium, and in a letter to the late Dr. Harvey, of Dublin, he speaks of it as "a beautiful shrub, one mass of most delicate, pendent, pale lilac, campanulate flowers." The plant that first flowered at Kew (in the Palm house) produced ivory white flowers streaked with red; at least so they are depicted in the "Botanical Magazine," pl. 5797. A plate subsequently published in the "Illustration Horticole," represents the flowers of much the same colour, whilst in the accompanying figure they are of a decidedly lilac-purple, more nearly agreeing with Sanderson's first description. The genus *Mackaya*, of Harvey, was dedicated to James Townsend Mackay, LL.D., author of the "Flora Hibernica," and for many years the able superintendent of the Dublin University Botanic Gardens; but in Bentham & Hooker's "Genera Plantarum" it has been reduced to *Asystasia*, thus sharing a similar fate to the *Mackaya* of Arnott, a Cucurbitaceous plant, to which Blume had previously given the name of *Erythropalum*; but the glory of a plant is not in its name. W. B. HEMSLEY.

Forced Flowers.—The following note in reference to the long period over which the different classes of forced plants have been in bloom with us may perhaps be interesting. We have had Lilies of the Valley in flower from Christmas until the first week in July; these had been plunged in Cocoa fibre outdoors, and brought into the forcing house as wanted, a good freezing being I consider necessary to ensure quick forcing. Roman Hyacinths came in in the first week in October, large-flowering kinds at Christmas, and they lasted until the middle of June, the earliest being Grand Lilas, Grand Vainqueur, La Précieuse, Charles Dickens, Amy, Waterloo, La Tour d'Auvergne, Robert Steiger, and Norma. A quantity at a time was potted up and plunged out-of-doors, keeping some of them out of pots as long as possible, this being the only way to ensure very late flowering. Spiræas lasted from the end of January to the first week in July. Carnations were good all winter; we grow about 6000, and we are never without flowers all the year round; even now there are many perpetual bloomers in the conservatory, and they attract more attention than any other flowers, almost every one stopping to smell them. The best two whites are Princess of Wales and Marguerite Bonnett; the best two scarlets Daybreak and Florentine; and the best red, Vulcan; other fine kinds are Miss Jolliffe (blush); Lillie (bluish-purple, edged with white); Alice (fine yellow, edged with rose); Iorna (rose); and Conqueror (crimson). Bouvardias last well with us; those grown out-of-doors last summer, and lifted in the second week in September, commenced blooming in November and kept in flower all the winter; others which came in when these were over are still in bloom. Thus it will be seen that by judicious management the season of blooming of almost any plant, when grown in quantity, can be considerably extended, and that with but little trouble.—JAMES O'BRIEN, *Pine-apple Nursery, Maida Vale*.

Clematis lanuginosa.—Amongst wall climbers this *Clematis* stands in the first rank, as, in addition to its very large blossoms, it comes into flower after many of the other plants are over. We have it mingling with Wistarias, Banksian Roses, &c., and thus associated the large flowers are seen to advantage; in fact, a very important matter in the case of wall climbers is to select such a variety as will keep up a continuous display during the greatest possible length of time.—J. GROOM, *Linton Park*.

MA'KAYA BELLA

GARDENING FOR THE WEEK.

Flower Garden.

Every kind of hardy tree and shrub in this part of the country (and doubtless it is the same everywhere) has apparently enjoyed to the fullest extent the wet season, for without exception they are all making magnificent growth, and present a condition so vigorous both as regards colour and foliage as is rarely seen. But the picture has unfortunately another side, which is, that such growth means increased labour—at least, as far as ornamental grounds are concerned—in order to keep it from encroaching on walks, paths, vistas, and from injuring by overcrowding. It will therefore be necessary to give attention to these matters at once. Guard against pruning, however, in too formal a manner, and such work should be done with a knife; clipping with shears should only be had recourse to in the case of formal belts, screens, or hedges. Climbing plants, particularly Roses and Clematis, have also made extra vigorous growth and now require tying in, and picking off decayed flowers and seed vessels in order that they may continue long in a flowering state. Roses, indeed, of every description are all the better for having all bad flowers regularly removed, not more for the sake of neatness than for the encouragement of successional blooms. Excessive growth is also exhibited by many plants on rockworks, and here also there is danger of the stronger overpowering the weaker unless early attention be paid to them. The present is a very good time to propagate many of this class of plants by division. The propagating of bedding plants in ordinary seasons would be at this date in full operation, but the beds are not yet filled out, or in full beauty; therefore cutting them about ought not to be thought of; we must therefore be content to preserve the old plants and propagate during the winter and spring. A fortnight hence will be ample time to put in a few store pots of cuttings of such plants as do not lift well; amongst these are Petunias, Verbenas, Heliotropes, Lobelias, Coleus, Alternantheras, and Iresines. The tempest of Saturday night, the 2nd inst., destroyed what little hope we had left that bedding plants would this season attain to anything like perfection. Still, no pains ought to be spared to render them as attractive as circumstances will permit by the preservation to the fullest extent of neatness, both as regards the beds, turf, and walks.

W. W.

Carnations and Picotees.—Those plants that have been grown in pots for exhibition, and that have been carefully nurtured, will have ere now repaid the cultivator for all the care that has been bestowed upon them; and this season they really did require considerable attention early in the year. Ours were kept very late in frames, or were otherwise sheltered from cold winds and continuous rains until they were well established in their blooming pots. They were out-of-doors from about the last week in April until the middle of July, and by that time only about a score or two of blooms were showing colour. The pots were then carried into a house where they could be well exposed to light, but any flowers half expanded were shaded when the sun shone out rather brightly. If Carnations and Picotees are shaded too closely the colours are not nearly so bright as they otherwise would be, and some sorts, such as Mrs. Fred Burnaby (Turner), and Samuel Newman (Hooper), pale rose flakes, are quite spoiled by close shading. Plants out-of-doors are now coming into bloom, just four weeks later than usual. It is generally safe to fix Carnation and Picotee shows in London on or about the 20th of July. This year such displays should have been fixed for the 20th of August.

Dahlias.—These are now opening and very good the first blooms are. We have had a few fine days which have brought the colours out well; the whites and yellows are clear, and the darker tints very satisfactory. During the last few days Dahlias have made very rapid growth, which has necessitated stopping and also tying the leading stems carefully to the stakes. Select suitable side growths and use them for cuttings; they strike freely in an ordinary frame even if there is little or no bottom heat. If it is intended to exhibit, small bloomed kinds must be judiciously thinned out, but those that have large flowers inclining to coarseness should not be much thinned. It is also necessary to rather closely shade some of the blooms in order to bring out the delicate tints of the lighter sorts; for this purpose nothing answers better than a stout stake driven into the ground near the flower to be shaded; on the top of this nail a board about 9 in. square, in which a slit is cut to its centre wide enough to admit the flower stem. Let the latter be drawn into this slit until the back of the flower just rests upon the board. A clean 6-in. or 7-in. flower pot answers as well as anything for shading the flower. In most cases the hole in the bottom of the pot has to be stopped, in others it should be left open. It is well to stop the slit with Moss or something to keep out earwigs, which sbeiter themselves in any cool dark retreat, and make sad havoc of the Dahlia petals.

Gladioli.—The bulk of our collection has in ordinary seasons

been in flower by the third week in August. This year not a single plant is showing bloom; this seems likely to be a disastrous season for this flower. I have usually recommended seeds of Gladioli to be sown in pots in April, and a season like the present shows the wisdom of some arrangement whereby the pots can be removed to a warm corner of the garden or even kept under glass until the small corns have ripened. This season also proves that it is desirable to inoculate some of the later flowering sorts with those that flower some six weeks earlier.

Phloxes in Pots.—These are now beginning to prove useful for conservatory and greenhouse decoration; the delicate tints and sweet perfume of the flowers of such plants are more pleasing to most people than the glowing colours of zonal Pelargoniums, and those fond of zonals will find their beauty enhanced by mixing amongst them some plants of Phloxes. The pots in which they are growing require abundant supplies of water, and it ought to be mixed with manure water occasionally.

Delphiniums, Pentstemons, Antirrhinums, &c., make a fine display mixed with other plants in shrubbery borders, and they are more effective in the shapely long borders than in others where the space is limited. See that the stems are not allowed to hang loose; on the contrary let them be fastened to sticks as they increase in growth, but not too stiffly. Remove all seed pods and decaying leaves, and keep the ground if possible well stirred and free from weeds.

J. DOUGLAS.

Conservatory.

Flowers under glass are this year more acceptable than usual, as the summer bloom out-of-doors has been more meagre than ordinary, therefore every effort should be used to maintain in conservatories as good a display as possible. Where there is a good supply of Lilies, especially of *L. auratum* and the early and later-flowering varieties of *L. speciosum*, together with *Valottas*, *Tritonias*, hard-wooded greenhouse plants, *Fuchsias*, *Zonal Pelargoniums*, and the like, mixed with fine-leaved subjects, there will be no difficulty in keeping this structure sufficiently bright.

Pillar Plants.—Many of the plants classed as greenhouse climbers, and employed for covering the usual roof supports, are far from being fit for the purpose. They are often such strong growers that they quickly run up to the top, leaving the lower portion of the pillars, where their presence is much wanted, devoid of leaves. Where plants for use in this way are required they are usually wanted to give immediate effect, and for that purpose it is well to prepare them beforehand by growing them on in pots until they are large enough to produce some effect at once; if healthy young plants are got now and an extra shift given them, time will be gained. It is scarcely necessary to say that instead of having the shoots pinched so as to form bushy specimens, they should be trained erect, only stopping a few of the strongest growths at different heights to cause these to break out. Subjoined are a few of the best plants that I have found for the purpose: *Cantua dependens* bears deep pink flowers, produced like those of *Fuchsia corymbiflora*; this is only fit for a pillar, as its determinately erect habit makes it unsuitable for growing in the ordinary way. *Hovea Celsi*, the lovely blue flowers of which are unsurpassed by those of any *Pea*-blossomed plant, has a habit which just fits it for growing on pillars. *Habrothamnus elegans*, which is stronger in growth than the two preceding, can also be easily kept within bounds, and is likewise an excellent subject for the purpose indicated. *Mitraria coccinea* (the Scarlet Mitre-flower) is another effective plant in a position of this kind, as by annual judicious cutting-back it can be had in flower from the bottom up to any reasonable height. The old *Hoya carnosa*, which will succeed for many years in a very small pot, is nowhere seen to greater advantage than when trained to a pillar. The blue *Plumbago capensis*, too, needs comparatively little root-space, and grows up quickly; its foliage is always neat, and it will keep on for many weeks producing its handsome pale blue flowers. *Cianthus magnificus* and *C. puniceus* are both good pillar plants, which are not disposed to get too large. *Fuchsia corymbiflora* is never seen in better condition than when grown in this way. The red and white *Lapagerias* are also amongst the best plants that can be employed for the purpose; the only objection to their use being that as they get old they require considerably more root room than is afforded by the usually small space that is available at the foot of a greenhouse or conservatory pillar wherein to turn a plant out, and if kept in pots or boxes the arrangement of the house is generally such as to produce an unsightly appearance. Plants of any or all of these, well prepared beforehand, will, when transferred to the positions they are to occupy, soon obviate the disagreeable effects of bare pillars.

Greenhouse.

Large-flowering Cacti.—These undoubtedly rank amongst the showiest of greenhouse decorative plants. They are also easily

grown; indeed, they will exist under conditions such as few other plants could endure. By keeping them tied in an erect position the space which they occupy is very trifling, and thus managed they will stand up high in relief above the surface of lower-growing plants. A few good specimens interspersed when in flower amongst the more-usually-met-with greenhouse and conservatory subjects, give a character and variety to the whole. To train them in the way alluded to, it is only necessary to get some pieces of stout iron wire, about the thickness of an ordinary cedar pencil, and double the length to which the plants are intended to be grown; bend these in the middle, so as to bring the ends together in a way that they can be inserted deep down in the soil just within the rim of the pot; paint them green, and they will answer the required purpose for many years, whereas if wooden stakes are used, the plants, from their weight, necessitate these being so strong that they have a clumsy appearance, and, in addition, they soon rot off near the bottom. The flowers of *Epiphyllums* do not individually last long, but when the plants get strong they continue to yield a succession for four or five weeks, and well repay the little attention which they require. The main point in their cultivation is to pot them in material that cannot possibly get sour, as their roots will not live in soil when reduced to that state. Good loam, to which is added a liberal sprinkling of small potsherds, enough sand to keep it porous, and a little well-decomposed cow-manure, if such be at hand, will grow them well. Pot firmly, and when the plants get sufficiently large they will do for several years without any increase of root-room or the soil being disturbed in any way; but they should be given a little manure-water during the growing season. In order to ensure their flowering each year, the growth should be thoroughly matured, and to effect this I have found nothing so good as placing them for the next five or six weeks against a south wall, where the heads of the plants can be firmly secured against the brickwork. This not only keeps them safe as regards wind, but the roasting which they thus get has an effect something similar to the hot drying influences to which they are subjected in their native country. Whilst in a position of this sort until the end of September they will require very little water, and care must be taken that soil in which they are growing does not get over wet through rain or drip from the coping.

Imantophyllums.—These are alike useful for general decoration and for cutting, but to grow them satisfactorily and in a way that will admit of the plants increasing in size, they must have sufficient root-room. They bloom at different times of the year, according to the treatment which they receive, but mostly through the latter part of winter and spring. Immediately after flowering repot such as require more room, or break up large specimens where a number of smaller plants, as is ordinarily the case, are found more serviceable. They may be divided now, but I should not recommend their being parted into single crowns in the manner that they would bear before the growth was made, for although they usually keep making roots freely when there is no top growth going on, yet dividing them into too small pieces would most likely interfere with their blooming. In the case of plants which it is desirable to grow larger and that require more root-room, even if the growth is completed, it will be better to move them at once than wait until spring, as the next growth they make will be much benefited by it.

Hard-wooded Plants.—It is now time to place out-of-doors the greater portion of what are termed hard-wooded greenhouse plants grown in pots. There are two reasons why they should be subjected to open-air treatment for some weeks; one is that if kept wholly under glass many continue growing in a way that interferes with their setting bloom, and on that account they flower sparingly; the next is that with all plants at all apt to suffer from mildew the leaves by exposure become much harder, more solidified, and very much less liable to its attacks than they otherwise would be—in fact, there are many plants, such as *Boronia pinnata* and *Hedera tulipifera*, on which it is next to impossible to keep the foliage in a healthy condition through the winter except they are put out-of-doors. It was at one time usual to turn out almost indiscriminately all plants of this description considerably earlier in the summer than this, but I have found such a course to be a mistake; it curtailed the growth that many continue to make whilst they remain under glass, and early turning out has also the effect of producing a determination in the plants to bloom correspondingly earlier the following spring, which even for general decorative purposes is a loss, on account of their thus coming into flower all together instead of affording a succession, which, when they are inclined to bloom later, can be easily managed by keeping a portion a little closer than the others through the spring, so as to bring them on sooner. Again, if the plants are exposed for a long period through the hottest part of the summer, the smaller ones are liable to get into a stunted state, and the four or five weeks that now intervene between this and the latter end of September are

quite sufficient to effect the purpose required. Should the weather become very hot and dry, it would be well not to put them where the sun at mid-day would be full upon them for the first week, as the sudden exposure under such conditions sometimes injures the leaves; but after a few days they may be brought into its full influence, except such plants as *Hedera* and *Boronia*, which are better where the sun will not shine straight upon them during the hottest part of the day. They should stand on a bed of coal ashes sufficiently thick to keep out worms, and in the case of anything but small specimens the sides of the pots next the sun ought to be shielded with pieces of mat or old canvas; small plants may be set near enough together for the heads of one row to shelter the pots of those behind them. Previous to turning out see that all are free from red spider and green fly. Everything of the character of *Pimeleas* that are subject to red spider should be freely syringed every afternoon when the weather is bright.

Pelargoniums.—The earliest headed-down large-flowered varieties of these will be now ready for potting; they should at once be shaken out and have their roots reduced proportionately with their size. Specimens that have got as large as may be required will need more of the small roots now in a matted condition removed than younger stock. All the larger plants will be better for being placed for a time in pots a size smaller than those in which they have flowered. Use the soil in a sufficiently moist condition, but not too wet; good turfy loam, with about a fifth of well-rotted manure, and sand proportionate to the nature of the loam, will suit them best, ramming the soil into the pots to make it quite close and firm. Put them in pits or frames with the lights on, but tilted so as to give some air in the day time, closing them down in the afternoons to assist the formation of fresh roots. Give no water to the soil for a fortnight or three weeks except such as reaches it from the syringing which the plants should receive every afternoon when closing up. In the case of fancy varieties it is not advisable to carry the disrooting process so far as in that of the larger kinds; in other respects similar treatment will suffice.

Large-flowered Pelargoniums and such of the now numerous decorative kinds—the latter so useful for general purposes—that have been kept in greenhouses or conservatories on account of their flowering continuously, should at once be turned out-of-doors to get their wood ripened previous to their being cut in; three or four weeks will effect much in this direction, and the plants will break much better when headed back than if kept wholly under glass.—T. BAINES.

Hardy Fruit.

The weather, aphides, birds, and—the last arrivals—wasps seem this season determined to render our hopes of anything like a fruit crop futile. Of course, the weather we cannot alter, but with the others a resolute will and hard work may successfully grapple. For aphides, syringe with soapsuds or Tobacco-liquor; against the depredations of birds, net up the fruit and use the gun freely; and for wasps search out their nests and destroy them. Apricots are now ripening, and blackbirds, thrushes, and even squirrels are partial to them the moment they are eatable. It is therefore wise to look over them every morning for the purpose of safely storing all that would be likely to tempt the almost insatiable appetite of these pests. Morello Cherries and Currants that are required to be kept must be at once thickly netted up. I find that even wasps do not face the finer make of hexagon netting, and this is infinitely preferable to mats, which do not admit sufficient air and light, and consequently the fruit becomes mildewed, and the trees get permanently injured. Trees and bushes from which the fruit has been gathered should have all surplus wood cut out. I refer more particularly to Currants and Gooseberries, which in this respect do not, as a rule, receive the attention which they merit, and which an improved and greater amount of produce well repays, not to mention the pleasure which the sight of well-cared-for fruit bushes always produces. Early kinds of Pears, such as *Citron des Carmes* and *Jargonelle*, ought to be gathered as soon as the faintest signs of maturity present themselves, for, if allowed to fully ripen on the trees, they get mealy, and do not keep so well; neither kind will, however, keep in good condition many days, and therefore it is not worth while to have more than one or, at most, a couple of trees of these sorts in any collection. Williams' *Bon Chrétien* is also approaching maturity, and in some measure the above remarks also apply to this kind, but its season may be prolonged by gathering the fruit at various times, say a part now, and the remainder on two other occasions at intervals of a few days. Any trees that are bearing a full crop of fruit may be assisted to perfect it by sprinkling guano about them, to be washed down by the rains. Peaches, Nectarines, late Pears, and Apples will all be much benefited by such a dressing. Over-luxuriant trees should be noted for the purpose of root-pruning when the proper time arrives for the performance of that operation; meanwhile, cut off all the

strong watery shoots, and thin out others to a moderate extent in order to ensure consolidation and ripeness of the remainder. All kinds of fruit trees may now have their new growths finally fastened to the walls or trellis. Avoid overcrowding when doing this, as it is necessary, considering the present immature state of the wood and the problematical character of the weather, that every leaf should have breathing space and the fullest exposure. Preparatory to fruit harvesting, fruit rooms should now be well cleared out, the walls lime-washed, shelves and tables repaired, and defective ventilation and drainage made good; unless these two latter are effective it is impossible for fruit to keep well.—W. W.

Extracts from my Diary—August 18 to 23.

FLOWERS.—Potting seedling Primulas, the result of crossing double and single kinds. Cutting seed-bearing stems off Mignonette and laying them on paper to ripen. Breaking up clumps of *Dactylis elegantissima* for use in spring bedding and planting them. Shifting double Primulas from 3-in. pots to those in which they are to flower. Potting a few Souvenir de la Malmaison Carnations for specimens. Chopping up soil and mixing with leaf-mould and rotten manure for Cinerarias. Re-arranging plant houses. Propagating bedding plants. Sowing beds of East Lothian Stocks; also Golden Pyrethrum. Taking up Chrysanthemums grown in borders and re-planting them in herbaceous borders. Making a trellis in Fig house and training *Maréchal Niel* Rose on it. Shifting *Poinsettias* from cutting pots into those in which they are to flower. Putting in cuttings of *Pelargonium Vesta*, *Happy Thought*, and *Robert Burns*.

FRUIT.—Tying-in leading shoots of young Melons just planted. Cutting shanked berries out of *Trebbiano* Grapes. Gathering all ripe Plums. Thinning Grapes in late Vineries where too thick. Pruning in Pear shoots. Planting Strawberries. Gathering all ripe Morello Cherries for bottling. Top-dressing Melons and fertilising their flowers. Taking nets off Morello Cherries and putting them on Peach wall to keep off wasps.

VEGETABLES.—Planting Moss Curled French, and Batavian Endive. Sowing last crop of summer Spinach. Digging Scotch Blue Potatoes (the last in garden), and raking ground over for next crop. Sowing Mustard and Cress. Staking and moulding up last crop of Peas—*William I.* and *Challenger*. Watering Celery, Lettuces, and last-planted Greens for winter use. Preparing for digging main crop of late varieties of Potatoes. Gathering all *Scarlet Runners* and *Capsicums*. Cutting all ridge Cucumbers that are ready for use.—R. GILBERT, *Burghley*.

THE CULTIVATION OF BOG PLANTS.

A DISTINCTION should, I think, for practical purposes be drawn between bog plants and water plants, on the one hand, and marsh plants on the other. There are many plants, such as *Ranunculus Lingua*, *Lythrum Salicaria*, *Menyanthes*, and *Butomus*, which are so distinctly water plants as only to require their roots to be in the mud below constantly present water in a less degree than the *Water Lilies*, *Frog-bit*, *Stratiotes*, and other submerged and floating plants which cannot live in any other condition. Then there is another group of plants, which, though often found growing in water, and even more flourishing there than elsewhere, yet do very well in moist earth, such as the *Caltha*, *Spiræa Ulmaria*, *Geum rivale*, *Chrysosplenium*, *Eupatorium*, *Bidens*, *Symphytum*, *Lycopus*, *Lysimachia vulgaris*, and *Leucojum*. The majority of these seem to be but slightly, if at all affected by the stagnation of the water, in the soil. *Geranium pratense*, *Vicia cracca*, *Epilobium hirsutum*, *Circea Pulegioides*, and *Solanum Dulcamara*, can hardly be classed with these marsh plants, since they are so at home in very unmarsh-like situations. Then there is another distinct group of plants, the essential pre-requisites for successful cultivation of which are, I believe, a soil constantly saturated, but preferably never stagnant, and, as far as possible, a moist and, I think, a cold atmosphere. These are what should be distinctly termed bog plants. Such are *Viola palustris*, *Parnassia*, the *Droseras*, *Pinguiculas*, *Anagallis tenella*, and *Narthecium*. These I have observed to flourish most in exposed upland bogs supplied by springs, where the sun renders the air moist without drying up the water, but where they are also exposed to the fresh, cold air. In these groupings I have kept purposely to British plants, as those with whose habits I am most familiar, and have hardly mentioned any which are not worthy of cultivation.

144, Kensington Park Road.

G. S. BOULGER.

leaves of this *Pæony* will be found very useful for finishing them off. I do not know of any other hardy plant so suitable for this purpose, the leaves being of just the right size, very firm, and forming, when in position, a neat fringe of glossy, finely divided foliage, much resembling in form, and really rivalling, that of many of the *Fern* tribe in beauty. A few vigorous specimens planted in good soil will furnish an abundance of leaves throughout the summer.—JOHN CORNHILL.

Winter Cucumbers.—Where Cucumbers are in demand during the winter months seed should be sown without delay. I find that the best plan is to sow single seeds in small pots; they vegetate quickly at this season, and the young plants should be shifted into larger pots as soon as may be necessary, keeping them near the glass, and well exposed to the air, in order to induce a sturdy growth. Large pots or boxes answer well for winter work, as the Cucumbers may be grown on back shelves of Pine pits or in similar structures where sufficient heat is maintained to keep them growing freely, but they will not be satisfactory unless a minimum temperature of 65° be maintained in the severest weather. If planted out in beds where hot water pipes supply the bottom heat, I find it a good practice to put a good thickness of bundles of heather under them. These allow the heat to rise regularly and gently, and also provide ample drainage. As regards soil, we rely principally on turfy loam, making it rather lighter for winter than for summer crops, by adding peat or thoroughly rotted leaf soil or hotbed manure. We plant on mounds or ridges, and keep adding a little fresh soil as the roots show themselves on the surface. Abundance of tepid rain water and weak liquid manure, keeping the foliage clean by timely fumigation, and attention to thinning both fruit and foliage, cannot fail to produce good results, as no plant cultivated can vie with the *Cucumber* as regards weight of produce. As to kinds we rely principally on *Rollisson's Telegraph*, a variety which usually shows five or six fruits at a joint, and which requires severe thinning. The number of fruits that some of our plants have perfected is almost incredible.—J. GROOM, *Linton, near Maidstone*.

Cross-bred Potatoes.—It would seem as if the Potatoes of the future would be the produce of American kinds fertilised with some of the best English sorts. An Anglo-American race, combining the size and heavy cropping qualities of the one with the form and fine table qualities of the other, securing from this cross hardier constitutions, will probably prove eventually to be the best cure for the disease. Already as mere chance seedlings from the *Early Rose*, but evidently fertilised in some way by other pollen, we have *Magnum Bonum* and *Schoolmaster*, both fine cropping kinds withstanding the attacks of the disease better than most others, and offering some promise that may ultimately lead us to the desired end. Mr. Robert Fenn, the well-known Potato raiser, has in hand for the fourth year of trial a number of seedlings raised from American kinds fertilised with English pollen, some having handsome-coloured tubers and others as white as snow, but all presenting a fine productive break. I have just lifted a number of seedlings, the produce of two Anglo-American crosses, the one *Extra Early Vermont*, crossed with *Early Market* and *Success*, a large *Snowflake* variety, crossed with the new *Woodstock Kidney*. Of the first cross two only have been selected, as these present what has been so long desired, pure white skin, duplicates of *Early Rose*, with all the best qualities of good English kinds. The other cross gives about a dozen selections, several dwarf and early, others later and robust, and all heavy croppers. I hope to find amongst these, sorts that will excel both *International* and *Magnum Bonum*, and that will produce crops quite a month earlier than the latter.—A. D.

Potato Crops in Meath.—The very wet and cold season which we have had has caused the Potato crops to be fully a month later than usual. Early Potatoes are good, especially those that were planted on freshly-trenched ground; those planted in the fields, such as *Early Rose*, *Chimax*, *Snowflake*, are very poor, being soft, and very few to the root. Late ones, such as *Champion*, *Flukes*, and *Scotch Donns*, are worse still. Plenty of top has been made, but few tubers; disease has also appeared in not a very mild form, and it is spreading rapidly.—JOHN CLEWS, *Headfort, Kells*.

Potatoes in Worcestershire are unusually late, but they were strong and healthy up to the last ten days, when the disease has manifested itself generally, and is now making rapid progress. The season being so late, too, the tubers are not yet in a sound state for lifting; even the early sorts are still tender. The crop is fine, and the quality good, and with favourable weather even the large kinds would soon be fit for harvesting. Should wet weather continue for any length of time, the late sorts must certainly suffer severely.—GEORGE WESTLAND, *Witley Court*.

Little Wonder Pea.—This is a first class dwarf Pea and one well suited for small gardens, for while it requires very few sticks and grows only 2 ft. high it is covered with a load of fine pods equal in quantity to many of the tall sorts.—G.

Fennel-leaved Pæony.—Where it is the custom to make bouquets of ordinary summer flowers in an informal natural style, the

THE KITCHEN GARDEN.

TRIAL OF CABBAGES AT CHISWICK.

By A. F. BARRON.

THE number of truly distinct or typical varieties of Cabbages is not very extended, but their variability of character and appearance has led at all times to an almost endless multiplication of names, which are most confusing and misleading. The necessity for arrangement and classification of the numerous names of Cabbages found in trade catalogues which has long been apparent, induced the Fruit Committee to institute a most comprehensive trial under the same conditions of all the varieties and supposed varieties that could be procured. Two trials or examinations were made. Firstly, from seed sown early in March, the Cabbages coming in for use in autumn. This formed the most comprehensive trial, the most of the varieties showing their peculiar characteristics to great advantage at this season, the cool, moist autumn weather being extremely favourable to their proper development. At this trial the greater part of the synonyms, &c., were determined, and their adaptability or otherwise for autumn use noted. Secondly, from seed sown in July, the Cabbages coming in for use the early part of the following summer. In this trial the synonyms previously determined were not included, the typical or distinct sorts chiefly being tested, including all those of doubtful character which were not satisfactorily arranged at the autumn examination. In this way the whole of the typical varieties were tested twice, both as summer and autumn Cabbages, and their proper seasons noted.

For convenience and simplification, the whole of the Cabbages have been arranged in three general classes, as follows, which are fairly well defined:—

1. Garden Cabbages, or Varieties Suitable for Garden Culture.—This is the principal class, and includes all the smaller and finer forms of the Cabbage, which mostly form their hearts quickly, and are of good quality. Those that are cultivated for the leaf-stalks chiefly are distinct species, the flowers being white instead of yellow.

2. Field Cabbages, or Varieties Suitable for Growing in Fields for Cattle.—This class includes all the large-growing and coarser varieties, generally termed Dutch or Drumhead. In a horticultural sense these are of inferior importance to the garden varieties, and need not have been tested at all excepting for the purpose of classification. Their peculiar merits cannot be determined by garden cultivation, although some of them in certain stages and seasons may be very serviceable.

3. Red or Pickling Cabbages.—This class is sufficiently well defined to require no explanation. Being of a red or purplish colour, they are, on that account, preferred for pickling to the green varieties.

From these three general classes the various types or typical varieties—that is, such varieties as appeared to possess sufficiently distinct features of a permanent character—have been selected and carefully described; photographs were also taken of the entire number for future reference, the oldest and most generally adopted name being in all cases preferred. Varieties under other names which were considered identical are given as synonyms, and those varying somewhat, either as to size or season, &c., but possessing the same general characters, are given as selections or varieties. Thus, in the Early York type, the Tom Thumb Early Dwarf is but a finer selection, and in the Nonpareil type, although there is a decided difference in the general appearance of the finer forms of Carter's Heartwell and Wheeler's Cocoa-nut, for all practical purposes they are properly classed as varieties of the Nonpareil.

In this way the whole of the varieties of Cabbages have been reduced to the comparatively small number of

Garden Cabbages	21	Typical Varieties.
Field Cabbages	16	" "
Red or Pickling Cabbages	2	" "

The great tendency of the whole of the Cabbage tribe to variation of character is pretty well understood by most good cultivators and seed growers. It is a matter of selection—good or bad stocks, early or late forms, large or small, &c., being readily produced according to the attention bestowed in the saving of the seed. True or pure stocks are only maintained by the most careful and constant selection of the particular form desired, and the saving of the seed. Seasons, however, and soils also, alter the appearance of Cabbages very much; also the periods of sowing and of planting. The produce, for example, from the same bag of seed may one season be very true, whilst in the next they appear mixed, some late, some early, &c. Some of these variations, being considered improved forms, are selected, a new name is given, and so new (?) varieties are introduced.

Classification of Cabbages.

CLASS I.

Garden Cabbages or Varieties suitable for Garden Culture.

1. ATKIN'S MATCHLESS.
2. BACALAN.
Variety. Late Bacalan.
3. EARLY BOULOGNE.
Synonym. Pêtin de Boulogne.
4. EARLY YORK.
Synonym. Small Oxheart.
Varieties (Superfine Early.
or Tom Thumb Early Dwarf.
or Selections. (Ear'y Dwarf York.
5. ENFIELD MARKET.

Division 1, Early Stocks.

- Varieties (Sproboro
or Raymeadow.
or Selections. (Improved Cabbage.

Large White Schwein-
fûrth
12. ST. DENIS.
13. Synonym. St. Denis Large Drumhd.
14. VAUGIRARD.

B.—Varieties partaking of the Borecole character, producing but little heart.

14. FEARNOUGHT.
15. THICK-LEAVED.
16. GREEN GLAZED AMERICAN.
Synonym. Glazed Cabbage

CLASS III.

Red or Pickling Cabbage.

1. DARK RED DUTCH.
Varieties (Dark Red Erfurt
or Selections. (Early Dark Red Erfurt
Erfurt Blood Red
Small Red
2. RED DUTCH.
Varieties (Drumhead Red
or Selections. (Large Red Drumhead
Large Red

1. Atkin's Matchless (Nutting & Sons, Minier & Co., Veitch & Sons).—Plant of a dwarf, compact habit of growth. About 9 in. high. Leaves, the outer about 18 in. broad, spreading, somewhat crumpled; of a very dark green colour. Heart small, broad at base,

Drumhead.

Habas Drumhead.

Dax Drumhead.

Pomeranian.

Late Bacalan.

Early Bacalan.

Large Fringed.

Large Red.

tapering to a sharp point, very firm and solid. This is a very distinct variety of a deep green colour, varied only by slight shading of red on the edges of the outer leaves at times. An excellent small early Cabbage for autumn use.

2. American Early. See Early American.

3. Blenheim (Nutting & Sons).—See Enfield Market. Good stock.

4. Bacalan (Carter & Co.; Vilmorin).—Plant of tall, strong, but compact growth; from 16 in. to 18 in. high, with long stem. Leaves broad, thick, incurving, with the edges reflexed, and wavy in outline. Hearts large, obovate in shape; from 6 in. to 8 in. in diameter; very solid and excellent. A very handsome and distinct Cabbage. Succeeds either for autumn or spring sowing.

5. Bacalan, Late (Carter; Vilmorin).—A somewhat later form of the preceding.

6. Battersea.—See Enfield Market.

7. Bleichfield Giant (Benary).—Plant dwarf, resting on the ground. Leaves large, spreading, having a bright green shining appearance. Hearts large, flat, and solid, like St. John's Day; very tender and excellent. A very fine early variety of the Drumhead, suitable for autumn use. Sow in spring.

8. Bloomsdale Early (Carter).—This sample contained a mixture of several varieties.

9. Brunswick (Dippé Bros.).—Inferior stock. See large Brunswick.

10. Braganza.—See Couve Tronchuda.

11. Carter's Heartwell.—See Heartwell or Nonpareil.

12. Cattell's Reliance (Veitch & Sons).—See Enfield Market.

13. Chou Joannet (Vilmorin).—See St. John's Day.

14. Cocoa-nut, Wheeler's (Carter, Nutting, Minier).—See Nonpareil. This is a very fine smooth rounded-leaved selection of the Nonpareil, of fine regular conical form.

15. Cornish (Nutting).—Plant tall, having a stout stem of about 8 in. Leaves large, spreading, with wavy serrated outlines; light green in colour. The inner leaves much crumpled and serrated, forming a loose heart. This is a variety of Cabbage much cultivated and esteemed in Cornwall for its thick fleshy midribs, but it is much inferior in this respect to the Couve Tronchuda.

16. Cœur de Bœuf petit (Leroy).—See Little Pixie.

17. Cœur de Bœuf gros hâif (Leroy).—See Large York.

18. Couve Tronchuda (Carter, Vilmorin).—Plant of medium size, on short thick stem. Leaves, the outer large, broad, with short very thick fleshy stalks and midribs: the colour pale green, with the ribs pure white; hearts very irregularly formed, but sometimes very solid. This is a variety of Cabbage largely grown about Braganza in Portugal, and is of excellent and distinct quality. The fleshy midribs of the leaves are the only parts eaten, being cooked like Seakale. It is somewhat tender; requires to be sown early in spring for use in autumn. Flowers white.

19. Couve Murciana (Barr & Sugden).—Plant tall, loose growing; leaves large, deep green, with thick fleshy midribs; forms a loose heart. This is allied to C. Tronchuda, but much inferior.

20. Couve Pucco (Barr & Sugden).—See Couve Tronchuda.

21. Curled Tronchuda (Vilmorin).—Plant of tall robust growth. Leaves spreading on long thick stalks; much cut and feathered down the stalk, waved and curled along the edges, which are deep green, with the palm flat and almost white; very thick and fleshy. This is very distinct from the Couve Tronchuda, and much inferior, but is often substituted for it.

22. Daniel's Defiance (Nutting & Son).—See Enfield Market. Fine selection.

23. David's No. 1 (Nutting & Son).—See Enfield Market.

24. Dwarf Drumhead (Nutting; Veitch).—See Quintal Drumhead.

25. Dwarf Early (J. Ellam).—See Nonpareil. A very fine selection.

26. De Tourlaville (Vilmorin; Carter & Co.).—Plant of tall robust growth, on long stem. Leaves medium-sized, roundish, on long stalks; deep green. Forms large hearts quickly, which are about 7 in. in diameter, of obovate form, very firm and solid. A distinct variety. Stock not very pure.

27. Le Mortagne (Carter & Co.).—Plant dwarf on very short stem. Leaves spreading, the outer broad, flat, and smooth, the inner somewhat cupped or closing over the hearts; of a pale glaucous green colour, faintly tinged with purple. Hearts large, 8 in. in diameter, flat, very firm and solid; forms early, and keeps long in good condition. Allied to the Drumhead section.

28. Dark Red Dutch (Vilmorin).—A very early variety of Red Cabbage; hearts small, deep purplish red, fleshy, crisp and excellent. Sow in spring for autumn.

29. Dark Red Erfurt (Vilmorin).—Similar to Dark Red Dutch. Fine variety.

30. Dax Drumhead (Carter; Vilmorin).—Plant very dwarf, resting on the soil. Leaves very large, broad, spreading, somewhat crumpled and cockled; of a light green colour; hearts formed quickly, very broad and quite flat, not very solid; very crisp and tender. Very much resembles Habas Drumhead.

31. Drumhead.—See Late Flat Dutch.

32. Drumhead Early Dutch (Vilmorin).—See St. John's Day Late.

33. Drumhead Red (Nutting & Son).—See Red Dutch.

34. East Ham (Carter; Minier; Nutting).—See Enfield Market.

35. Earliest French (Carter).—This sample contained a mixture of several varieties.

36. Early American (Veitch).—A large and very early variety of the Drumhead section. Hearts somewhat more pointed than the ordinary form. Excellent.

37. Early Battersea (Minier).—See Enfield Market.

38. Early Boulogne (Carter & Co.).—Plant of small, compact growth; height 10 in. Leaves small, rounded, spreading and curving backwards from the heart, which thus appears to stand very bare. The leaves are thick, with longitudinal white, fleshy veinings; hearts small, of conical shape, with broad base; very firm, crisp, and tender. This is the earliest of all the Cabbages, but soon bursts, and is inferior to others which are a little later.

39. Early Bleichfield Giant (Benary).—See Bleichfield Giant.

40. Early Dutch Drumhead (Vilmorin).—See St. John's Day Late.

41. Early Dark Red Erfurt (Vilmorin).—A small but early variety of Dark Red Dutch.

42. Early Ingreville (Carter).—See De Tourlaville.

43. Early Dwarf York (Minier).—See Early York. A very fine selection.

44. Early York (Carter; Nutting; Veitch; Vilmorin).—Plant of small compact growth on a short slender stem; height averaging from 10 in. to 12 in. Leaves few, erect, of rounded form, and slightly cupped; very smooth and even; of a deep green colour, with a thick coating of bloom and a few white venations. Hearts small, formed very quickly, of an ovate form with a rounded top; very firm and solid. A very distinct type of Cabbage of very excellent quality. Summer and autumn use. To be sown in spring.

45. Early Large York (Minier).—See Large York, of which this is an early selection, and having the leaves glossy.

46. Early Normandy (Carter).—See Little Pixie.

47. Early Wynan (Carter).—A mixed stock.

48. Early Rainham (Minier).—See Enfield Market.

49. Early Jersey Wakefield (Veitch).—See Jersey Wakefield.

50. Early Winnigstadt (Veitch).—See Winnigstadt.

51. Enfield Market (Carter; Minier; Veitch).—Plant large on short stem. Leaves large, broad, frequently much cockled, and with thick fleshy ribs; bright green in colour. Hearts large, broadly obovate and irregularly pointed; very solid, crisp and tender. This is the great London market Cabbage, and the one most generally cultivated throughout the country under many names, which differ only in proportion to the purity of stock and early or late selections. Formerly it was better known as Vanaek, subsequently Fulham or Battersea, but at the present time Enfield Market is the best known; hence its adoption.

52. Erfurt Blood Red Earliest (Benary).—See Dark Red Dutch. A small and fine selection; very early.

53. Erfurt Large White (Benary).—A large and fine late variety of the Drumhead.

54. Erfurt Small White (Benary).—A mixed and inferior stock of Drumhead or Brunswicks.

55. Erappe Drumhead (Vilmorin).—See Monk's Cabbage.

56. Fearnought (Carter).—Plant of strong robust growth, about 2 ft. in height, spreading. Leaves on long stalks; narrow, much waved and irregular in outline like Broccoli; of a deep green colour, the ribs reddish. Hearts small, very loosely formed. A very hardy sort, but very coarse and worthless.

57. Fielder (Benary).—See Pomeranian.

58. Flat Dutch Drumhead (Minier).—See Quintal.

59. Fottle's Brunswick (Carter; Stuart and Mein).—See Large Brunswick.

60. Fumel or Femelle (Vilmorin; Carter).—Plant rather short, spreading. Leaves large, rounded, on long stalks; much crumpled; of a very pale green colour, and very soft in texture. Hearts very large, broad, flat like the Drumhead; very loose. This is a very peculiar and distinct Cabbage. Hearts form very early, but soon open out again and run to seed.

61. Glazed Cabbage (Carter).—See Green Glazed American.

62. Gibson's Drumhead (Nutting).—See Large Brunswick.

63. Glen Dwarf Drumhead (Nutting).—See Drumhead.

64. Green Glazed American (Vilmorin).—Plant tall, on long stem. Leaves few, medium sized, rounded, of a shining deep green colour.

Dwarf Red.

Winnigstadt.

Dwarf York.

Dwarf Early Erfurt.

Vaugirard.

Dwarf Oxheart.

Sugar-loaf.

St. Denis.

Brunswick.

Large Oxheart.

Large York.

Short-stalked Dutch.

Forms very small hearts. Can scarcely be termed a Cabbage, more properly a Borecole. Much appreciated in America, where it is almost exclusively grown.

65. Heartwell (Carter).—A very fine close-growing selection of the Nonpareil.

66. Habas Drumhead (Carter; Vilmorin).—Plant very dwarf, resting on the soil. Leaves large, about 2½ ft. in diameter, lying flat, much crumpled, of a very pale green colour, and very thin and tender. Hearts form quickly, very broad and flat, frequently 10 in. to 12 in., and not more than 2 in. in thickness. Very soft and rather tender. A very pretty and distinct early flat Cabbage.

67. Hardy Green Colewort (Carter; Veitch).—Plant of compact growth; about 12 in. in height. Leaves of medium size, of a very deep green colour, with a tinge of red. Hearts formed very slowly and late, medium size, of a broad conical form. An excellent variety for late autumn use; very hardy. It is generally sown in May, planted out thickly for use in autumn and winter, as Coleworts or Greens. Very fine quality.

68. Henderson's Early (Carter).—A variety of the Drumhead. Inferior.

69. Improved (Stuart and Mein).—An early selection of Enfield Market; very good.

70. Improved Drumhead (Carter).—See Quintal.

71. Ingreville (Vilmorin).—See De Tourlaville.

72. Jersey Wakefield (Carter; Veitch).—A large strong-growing form of the Enfield Market type, but much coarser and inferior.

73. Kemp's Incomparable (Carter & Co.).—See Enfield Market.

74. Large Brunswick Short Stemmed (Vilmorin).—Plant very dwarf, almost resting on the ground. Leaves very large, broad, lying flat on the surface, very thick and smooth; of very pretty pale glaucous green. Hearts large, flat, averaging about 10 in. in diameter. Very smooth, even, and regularly formed, and very firm. Hearts form early, and keep long in good condition. A very good variety of the Drumhead type.

75. Large Late Flat Brunswick (Vilmorin).—See large Brunswick Short Stemmed.

76. Large White Brunswick (Benary).—See Late Flat Dutch.

77. Large Erappe Drumhead.—See Monk's Cabbage.

78. Large Green Colewort (Minier).—See Hardy Green Colewort.

79. Large Mortagne Drumhead (Vilmorin).—See De Mortagne.

80. Large Oxheart (Vilmorin).—See Large York.

81. Large St. John's Day (Carter).—See St. John's Day Late.

82. Large White Solid Magdeburg (Benary).—A good selection of Drumhead or Flat Dutch.

83. Large White Schweinfürth (Benary).—See Schweinfürth.

84. Large Red Drumhead (Vilmorin).—See Red Dutch.

85. Large Red (Carter).—See Red Dutch.

86. Large Nonpareil (Nutting).—See Enfield Market.

87. Large York (Carter; Vilmorin).—A large tall-growing form of the York Cabbage, of exactly similar appearance to the early York, but growing to more than twice its size. Very excellent. This is the large Oxheart of the French.

88. Large York (Veitch; Nutting).—An early hearting form of Large York, having the leaves glossy or shining and destitute of the usual bloom.

89. Late Bacalan (Carter; Vilmorin).—See Bacalan.

90. Late Flat Dutch (Vilmorin).—Very large, and strong growing. Heads very large, solid; pale green. This is the ordinary Drumhead Cabbage, much grown in fields for cattle.

91. Late Purple Flat Pole (Nutting).—A large and late variety of Drumhead.

92. Little Pixie (Carter; Nutting; Veitch).—Plant of very small, close compact growth, averaging about 8 in. in height. Leaves short, rounded, smooth; of a light green colour. Hearts large for size of plant, of conical form, with a broad base and rounded points. Hearts form very early, and are of excellent quality. Good for late summer and autumn use. Sow in spring; may be planted 15 in. apart. This is the same as the small Oxheart of the French.

93. Louviers (Vilmorin).—A larger form and very fine selection of Little Pixie. Very good.

94. Marble Headed Mammoth (Carter).—See Late Flat Dutch.

95. Marbled Burgundy Drumhead (Vilmorin).—See Late Flat Dutch.

96. McEwen's Early (Nutting).—See Enfield Market.

97. Monarch (Nutting).—See Nonpareil.

98. Monk's Cabbage (Carter).—Plant large, spreading on a short stem. Leaves, the outer broad flat, the inner much cupped and somewhat reflexed; very thick and of deep glaucous green colour. Hearts large, roundish, flattened, from 7 in. to 8 in. in diameter; very deep green, tinged with red; very solid yet crisp and tender. A fine and handsome late Cabbage, Drumhead type.

99. Wyatt's Early (Nutting).—See Enfield Market.

100. Nonpareil (Carter; Minier; Nutting; Veitch).—Plant dwarf, seldom exceeding 12 in. in height; of close compact growth. Leaves

light green, of medium size, rounded at the point, somewhat cockled and crumpled. Hearts of broad conical form, from 4 in. to 6 in. in diameter, formed very early, very firm and solid, and of excellent quality. One of the most esteemed of Cabbages for general use. Not quite so large as Enfield Market, but of much the same character. The larger forms of the one may pass for the other, and *vice versa*.

101. Normandy.—See Little Pixie.

102. Oxheart Early (Vilmorin).—See Little Pixie.

103. Oxheart (Carter).—See Large York (Veitch).

104. Oxheart Large (Vilmorin).—See Large York.

105. Oliver's Monarch (Stuart and Mein).—See Nonpareil.

106. Paignton (Nutting).—See Cornish.

107. Plaw (Nutting & Son).—See Enfield Market.

108. Pomeranian (Carter; Vilmorin).—Plant tall, averaging from 2 ft. to 2½ ft., on long stem. Leaves large, of long pointed form and of a pale glassy green colour. Heads of long conical form, sharply pointed, averaging from 14 in. to 16 in., and from 6 in. to 8 in. in diameter; very solid and of good quality. A very distinct variety, the long pointed heads being very remarkable. Sown in autumn, becomes fit for use the following summer. An excellent sort in dry seasons.

109. Pomme d'Orion (Leroy).—Plant large, spreading, on short stem. Leaves large, broad, spreading, with a wavy outline, and somewhat reflexed, thus exposing and showing the heart rather conspicuously; hearts of medium size, obovate pointed, very fleshy, tender, crisp, and moderately solid. A distinct variety but not of much merit.

110. Portugal (Barr & Sugden).—See Couve Tronchuda.

111. Prefin de Boulogne (Leroy).—See Early Boulogne.

112. Précoce de Louviers (Vilmorin).—See Louviers.

113. Premium Flat Dutch (Carter).—See Late Flat Dutch. A large late variety.

114. Prompt de St. Malo (Leroy; Vilmorin).—Plant tall and rather thin. Leaves long, narrow; hearts large, of obovate pointed shape and of a light green colour; the ribs very prominent and fleshy; very solid, crisp and tender. An early Cabbage but stock very inferior.

115. Quintal or Cwt. Drumhead (Carter; Vilmorin).—Plant very dwarf, almost resting on the ground. Outer leaves large, broad, rounded, with wavy outline, those approaching the heart prettily reflexed along the edges, giving the plant a very distinct and handsome appearance. It is of a uniform light glaucous green colour; the ribs white and very prominent; hearts large, flat, averaging from 8 in. to 10 in. in diameter and from 2 in. to 3 in. in thickness; very solid yet tender and excellent; hearts form rapidly and keep well. One of the very best of the Drumhead section for garden cultivation.

116. Raymeadow (Wheeler).—An early and fine selection of Enfield Market.

117. Red Dutch (Minier; Nutting; Veitch).—Plant tall, of strong vigorous growth. Leaves large, rounded, of a dull purplish-red colour, very thickly covered with a greyish-blue bloom; hearts large, very solid, of a very deep red colour. Excellent. This is the ordinary Red Cabbage.

118. Robinson's Champion Drumhead (Nutting).—See late Flat Dutch.

119. Rosette Colewort (Carter; Minier; Veitch).—Plant of a very distinct style of growth, small, compact. Leaves small, rounded, short, cupped or incurved and hooding over heart, thus forming a perfectly flat or square top; of a deep green colour tipped with rose; hearts small, but becoming very firm if sown at the proper season. It should be sown in May and planted out about 15 in. apart for use in autumn as Coleworts or small Cabbages. If sown at other seasons it grows very differently, and is much inferior. Much cultivated in the market gardens round London, and deservedly esteemed.

120. Schweinfürth Quintal (Vilmorin).—Plant large and spreading, from 15 in. to 20 in. in height, on a short stem. Leaves thin, very large, broad, the outer flat and spreading, the others gradually becoming more cupped the nearer to the heart; colour pale green, shining or destitute of the usual bloom, the outer edges of the leaves tinged with dull red; hearts large or very large, roundish or obovate in shape, and seldom becoming very solid; may be easily crushed with the hands like a Lettuce. This is a very early variety of the Drumhead section, but unsuited for gardens.

121. Schweinfürth Early Drumhead (Minier).—See Schweinfürth Quintal.

122. Silver Leaf Drumhead (Carter & Co.).—Plant dwarf, like Short-stemmed Brunswick; heads large, flat. Leaves light green, tinged on the outer edges with dull red. Coarse.

123. Small very Early Erfurt Drumhead (Vilmorin).—Plant dwarf, almost resting on the ground; greatly resembling St. John's Day, but inferior in texture and quality. Leaves small, rounded, smooth; hearts of medium size, flat, very smooth, evenly formed, and very solid. A small early and very pretty variety of Drumhead.

124. Sprotboro (Nutting & Son; Minier).—See Enfield Market.

125. Small Red (Carter).—See Dark Red Dutch.
 126. Small Oxheart (Carter & Co.).—See Early York.
 127. St. Denis (Carter).—Plant dwarf, on a short stem, spreading. Leaves very large, thick, rounded, lying flat; of a deep green colour, with a very thick blue bloom. Hearts large, roundish, very firm and solid, some having a tinge of brown, but generally of a uniform deep green. Forms early and keeps long in good condition. A very pretty Cabbage.
 128. St. Denis Large Drumhead (Vilmorin).—See St. Denis.
 129. St. John's Day (Carter; Nutting).—Plant very dwarf, entirely resting on the ground, seldom exceeding 6 in. or 7 in. in height, and about 18 in. or 20 in. in breadth. Leaves spreading broad, very compactly placed; of a deep green colour. Hearts large, broad, flat, from 6 in. to 8 in. in diameter; very firm, solid, yet crisp, tender, and fleshy. Forms early, and is of excellent quality. One of the very best Cabbages for autumn use. Sow in April and plant out 15 in. apart.
 130. St. John's Day Early (Minier).—See St. John's Day Late.
 131. St. John's Day Drumhead (Veitch).—See St. John's Day.
 132. St. John's Day Early Drumhead (Vilmorin).—See St. John's Day.
 133. St. John's Day Late Drumhead (Vilmorin).—A larger and later form of St. John's Day.
 134. Strasburg Quintal (Benary).—See Quintal.
 135. Sugar Loaf (Carter; Nutting; Veitch; Vilmorin).—Plant of a very distinct character, of rather tall growth. Leaves long, erect, spoon-shaped, and much cupped; of a very pale green colour, but covered with a thick bloom, and leathery texture. Hearts of long ovate shape; formed very loosely, the leaves merely hooding over in the manner of a loose Cos Lettuce, so may be easily unfolded. Forms early, but of poor quality, not worthy of cultivation.
 136. Superfine Early (Vilmorin).—See Early York. A very fine selection.
 137. Thick-leaved (Carter; Vilmorin).—Plant of tall vigorous growth, on long stem. Leaves large, spreading, very thick and leathery; of a pale green colour, with very prominent broad white midribs and veinings, giving the plant a very white appearance. The edgings or borderings much waved in outline, and recurving over the heart very prettily. Heart medium size, broad, very solid, but is apt to burst open rather quickly. A very distinct but coarse and uncertain variety.
 138. Tom Thumb Early Dwarf (Minier).—See Early York. A very fine selection.
 139. Tourlaville (Vilmorin).—See De Tourlaville.
 140. Tronchuda.—See Couve Tronchuda.
 141. Vanack.—See Enfield Market. Vanack is the old and original name of the Cabbage now generally known as Enfield Market.
 142. Van Winkler's Flat Dutch (Carter).—See Drumhead or Flat Dutch.
 143. Vaugirard (Carter; Leroy).—Plant of medium height on short stem. Leaves large, broad, flat and smooth, very thick and fleshy, of a very deep green colour, with a thick heavy bloom, those near the heart somewhat waved and tinged with purple, like the red Cabbage. Hearts large, roundish, moderately firm and solid, but somewhat coarse.
 144. Vaugirard Winter Drumhead (Vilmorin).—See Vaugirard.
 145. Victoria, Harrison's (Harrison).—See Enfield Market.
 146. Wheeler's Cocoa-nut (Wheeler).—See Cocoa-nut or Nonpareil.
 147. Wheeler's Imperial (Nutting; Veitch).—See Nonpareil. A fine early selection.
 148. Winingstadt (Benary; Carter; Nutting; Veitch; Vilmorin).—Plant of medium size, on short thick stem. Leaves, the outer large, spreading, smooth; of a deep green colour, with a heavy bloom, and very thick and fleshy. Hearts very large, broad, conical, and sharply pointed; the point frequently twisted somewhat on one side; very solid, and of excellent quality. A very distinct and excellent Cabbage for late summer and autumn use; should be sown in August, or very early in spring.
 149. Winingstadt Sugar Loaf (Benary).—See Winingstadt.
 150. Wright's Market (Minier).—See Enfield Market.

Garden Cabbages arranged according to their seasons, representing all the types or typical varieties in cultivation:—

Early Varieties.

- | | |
|-----------------------|-------------------|
| 1. Atkins's Matchless | 5. Nonpareil |
| 2. Early Boulogne | 6. St. John's Day |
| 3. Early York | 7. Sugar Loaf. |
| 4. Little Pixie | |

Mid or General Season Varieties.

- | | |
|------------------------|----------------------|
| 8. Enfield Market | 11. Tourlaville |
| 9. Larze York | 12. Rosette Colewort |
| 10. Prompt de St. Malo | 13. Winingstadt |

Late Varieties.

- | | |

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 12.

THIS meeting, taken in conjunction with the exhibition of the southern section of the National Carnation and Picotee Society, was an unusually interesting one. Amongst its leading features were some superb collections of cut Roses, and fine groups of tuberous-rooted Begonias. Several new plants, submitted to the notice of the floral committee, were awarded First-class Certificates as follows:—

Gladiolus hybridus Lemoineanus (Lemoine).—A very fine variety, the result of a cross between *G. purpureo-auratus* and *G. gandavensis*, alluded to in another column.

Nepenthes Viellardi (Veitch).—A handsome Pitcher-plant, similar in habit to *N. distillatoria*, but very distinct from any other kind. It has deep green leaves with a singular hoariness on the upper surfaces, and also pitchers, which are of medium size, and entirely of a deep red colour.

Sarracenia formosa (Veitch).—A very elegant hybrid, raised between *S. psittacina* and *S. variolaris*. It partakes of the beautiful markings and peculiar form of the former species, combined with freer growth and the larger size of the latter.

Iris Kämpferi Charles Maries (Veitch).—A beautiful form of this popular hardy plant, with flowers of very large size, of a pale mauve tint, quaintly marbled with blotches of a darker hue.

Iris Kämpferi The Jersey Belle (Veitch).—Another novelty of chaste beauty; the standards in this variety are as broad as the falls, and are arranged on the same plane; they are pure white, with a bright orange spot at the base of each division.

Iris Kämpferi Sir Stafford Northcote (Veitch).—Similar in form to the foregoing, but larger in size, and of a rich deep purple, which forms a beautiful contrast to the orange spots on each segment.

Stanstead Rival (Laing).—One of the finest single-flowered Begonias yet raised. It is robust in habit, and has large glossy green leaves; the flowers are five-petalled, arranged in a saucer-like manner, and are of a rich deep crimson colour.

Coleus Tricolor (Cannell).—A superb variety, very distinct, and one which richly deserves the recognition accorded to it. It is of good habit, with moderate-sized leaves; its colour is a deep dull red, with a central broad band of bright red, and the margins of a rich emerald green.

Fuchsia Eclipse (G. Smith).—A pretty variety with a large double rich purple corolla and bright red sepals.

A Botanical Certificate was awarded to

Conandron ramondioides (Veitch).—A highly interesting Japanese plant, alluded to in another column.

In addition to these, several other new or rare plants were contributed from various sources. Messrs. Veitch & Son showed a very fine variety of *Cattleya gigas* named *Normani*, remarkable for its free-flowering tendency. The plant exhibited had six expanded flowers. The true *Vanda insignis* was shown in fine condition, as was also *Cypripedium euryandrum* and *Zygopetalum Sedeni*, two beautiful hybrid Orchids previously referred to. A remarkably well-grown plant of *Saccolabium Blumei majus*, with four racemes of flower, one of which was over 15 in. long, was also in this collection, as were likewise *Sarracenia Chelsoni* and *S. Stevensi*, two fine hybrid Pitcher-plants with highly-coloured and beautifully-netted

leaves. Other handsome hybrid Pitcher-plants were *Nepenthes Wrigleyana* and *Ratelifiana*, the result of crosses between *N. Hookeri* and *N. phyllanthora*. The same firm also sent some finely-flowered plants of the pretty *Olearia Haasti*, a hardy New Zealand shrub, and a basketful of the Japanese variety of the old *Dracocephalum Ruyschiana*. Besides the varieties of Kämpfer's Iris certificated were a fine reddish-coloured form named Sir Richard Wallace, Mrs. Cornwallis West, and Prince Imperial, all of high merit, and distinct in colour. Mr. B. S. Williams contributed *Cœlogyne Massangeana*, a handsome Orchid, with a long pendulous raceme of flowers of a creamy-white colour, the lip of which is streaked and spotted with rich chocolate. He also showed *Adiantum mundulum*, an elegant Maidenhair Fern of dwarf, compact habit. Messrs. F. & A. Smith, Dulwich, sent plants of the graceful feathery *Asparagus (A. plumosus)*, which will doubtless prove an excellent decorative climbing plant. A group of Balsams were shown by the same exhibitors, which, though their flowers were fine and double and rich variety of colour, showed unmistakably the lateness of the season. A well-grown plant of *Hydrangea paniculata grandiflora*, sent by Mr. Wills, admirably showed its free-flowering property and the pure whiteness of its blossoms. Messrs. Osborn & Sons, Fulham, exhibited a well arranged group of fine foliated plants, consisting chiefly of Palms, Crotons, Ferns, Dracænas, Sonerilas, &c. A fine bank of tuberous-rooted Begonias, shown by Messrs. J. Laing & Co., Forest Hill, comprised some remarkably beautiful seedlings, and several showed a marked advance on the existing kinds. The double white flowered *Alba plena* was shown amongst them, and also the delicate *Reine Blanche*, which is the best white yet shown. The same exhibitors also sent a large collection of Phloxes, consisting of most of the leading varieties of these showy plants. From Messrs. Lee & Son, Hammersmith, came a group of Begonias, amongst which were two fine varieties, viz., *Crimson King* and *Charmer*. Cut branches of a variegated variety of *Cornus Mas* named *auræa elegantissima* were also shown. Mr. Tong, Southgate, furnished well-grown plants of *Begonia*, *President*, and *Hecla*, also plants of *Begonia Lucienne Bruant*, a prettily mottled-leaved plant. Several Coleuses were shown by Mr. Lloyd, Brookwood Asylum, some of which were very handsome. A fine basketful of *Coleus Verchaffelti grandis* was shown by Mr. G. Weedon, Ealing, which as shown was decidedly superior to the type. Cut blooms of *Pelargoniums*, *French Marigolds*, *Antirrhinums*, and *Verbenas*, were sent by Mr. Cannell, Swanley, and were much admired, especially the *Verbenas*, of which there was a large collection, representing some of the finest kinds in cultivation, large both in truss and pip, and exhibiting much variety in colour. Cut flowers of *Tropæolums* and *French Marigolds* were shown by Messrs. J. Carter & Co., also some examples of their *Auricula*-flowered strain of *Sweet Williams*, the trusses and pips of which are large, and the colours pure and well defined. From the same exhibitor came several beautiful and distinct varieties of *Coleus*.

Roses.—An excellent collection of these came from the Waltham Cross Nurseries consisting of superb examples of the finest varieties; amongst them were the new *Duchess of Bedford*, which is undoubtedly one of the finest of new *Roses*; its flowers are large and of good form, rich velvety-crimson in colour overlaid with a purplish lustre. *Countess of Rosebery*, another beautiful *Rose*, was shown in fine condition, as were also several unnamed promising seedlings. *May Quennell*, *Baronesse Rothschild*, *Magna Charta*, *Paul Neron*, *Black Prince*, and many others were excellent, and were awarded a silver *Flora* medal. From the *Cheshunt Nurseries* came a similar contribution, which was similarly awarded. It contained fine examples of the leading varieties, amongst which were *Lady Darnley* and *Glory of Cheshunt*, two very fine kinds both as regards form and colour, especially the latter, which is of a brilliant hue nearly approaching scarlet. A silver *Banksian* medal was awarded to Mr. C. Turner, Slough, for several stands of *Roses*, amongst which was one filled with fine blooms of the well known *Alfred Colomb*, which still holds its own against all comers. Mr. Wilson exhibited a large *candelabrum*-like branch of the *Armenian Sea Holly (Eryngium giganteum)* grown in his garden at *Weybridge*.

Fruit and Vegetables.—A first-class certificate was awarded to *Melon Victory of Bristol*, a handsome and finely-netted variety sent by Mr. W. Carmichael, Newton Court, Bury St. Edmunds. Fruits of the singular *Himalayan White-stemmed Bramble (Rubus biflorus)*, which have a pleasant acid flavour, were sent from the Society's garden. Messrs. James Carter & Co. sent samples of their *Telephone Pea* for comparison with *Culverwell's Telegraph*, with which it has been alleged to be synonymous. The committee, however, decided that the two varieties were distinct, and confirmed the certificate awarded by it last year to Carter's *Telephone*. The same firm also showed a new *Pea* called *Carter's Stratagem*, and similar contributions were sent by Mr. Gilbert, Burghley, under the name of *Hobart Pacha*, and *Exeter Marrow Pea* came from Mr. Robert Veitch of Exeter.

NATIONAL CARNATION AND PICOTEE SOCIETY.

The annual exhibition of the southern section of this Society was held on this occasion at South Kensington, in connection with the Fruit and Floral Committee Meeting just referred to. Though the exhibitors were for the most part from the southern counties, there were contributions from as far north as Yorkshire. On the whole it was a fairly representative display, for most of the classes were well filled, and in most of them there was a keen competition. The class for plants in pots, however, was only represented by one exhibitor; they were, however, well grown, and were deservedly much admired, and probably would have been even more appreciated had it not been for the inevitable collars of white cardboard which encircled the flowers, an antiquated practice which should long ago have been obsolete.

First-class Certificates were awarded to

Picotée Dr. Abercrombie (Turner).—A large, full flower, with heavy red edge, the ground being pure white, and the petals smooth.

Picotée Baroness Burdett-Coutts (Turner).—A fine flower, large, and full, in the white very pure, and the purple edge well defined.

Carnation Heather Bell (Turner).—A beautiful variety, with the flowers unusually large and very full; petals crisped, and of a delicate bluish tint.

Carnation Coronor (Turner).—Also a beautiful kind, with fine, full blossoms of a rich deep cerise colour.

Picotée Clara Penson (Wilmer).—A well-formed large flower, with the white clear and pure, and a light purple edge.

The premier flowers in the exhibition were *Picotée Mrs. Payne*, a heavy rose edge, shown by Mr. Douglas, Loxford Hall, and *Carnation Sybil*, a well-marked rose flake exhibited by Mr. Turner. This exhibitor also took the highest award for the best twenty-four blooms of *Carnations*. Amongst these were *Sybil*, *Squire Trow*, *James Taylor*, *J. D. Hextall*, *Clipper*, *Mars*, *Graceless Tom*, *Mayor of Nottingham*, *Rifleman*, *Admiral Curzon*, *Sporting Lass*, and *G. F. Wilson*. Mr. Dodwell was equal first with a fine collection, including *Unexpected*, *James Douglas*, *Florence Nightingale*, *Mars*, *Annihilator*, *Christigala*, *Dreadnought*, *Sybil*, *William Murray*, *Admiral Curzon*, *Captain Stott*, and *James Merryweather*. The next in point of merit was the *Loxford Hall* collection, which comprised amongst others fine blooms of *Mars*, *Sarah Payne*, *Admiral Curzon*, *Juno*, &c. The best twelve included *Mrs. Llewellyn*, *George Rudd*, *James Merryweather*, *John Ball*, &c. Mr. Douglas was again second in this class with a good selection. The premier half-dozen blooms consisted of *James Douglas*, *Sybil*, *J. D. Hextall*, *Admiral Curzon*, *Sportsman*, and *Annihilator*. The exhibits in the class for single specimens of *Carnations* were numerous; *Admiral Curzon* was the best bloom amongst the *Scarlet Bizarres*, and the same kind took the third and fifth place. A seedling of Mr. Dodwell's and *True Briton* were second and fourth respectively. For *Crimson Bizarres* *J. D. Hextall* was the best flower; for pink *Bizarres* Mr. Douglas took all five places with *Sarah Payne*, *James Taylor*; for purple flakes *Squire Trow*, *James Douglas*, *Squire Meynell*, and *Juno* were placed in the order named; scarlet flakes were represented best by *Clipper* in the first and second places, *Sportsman* in the two following. *Sybil* was represented best in the rose flakes, also in all the other places except the third, which was taken by *John Keet*.

The best two dozen blooms of *Picotées* came from the *Slough Nurseries*, and comprised very fine examples of *Mrs. Allerof*, *Her Majesty*, *Dr. Abercrombie*, *Leah*, *Lady Baston*, *Baroness Burdett-Coutts*, *Zerlina*, *Lily of the Valley*, *Rev. J. B. M. Camm*, *Horace Mayor*, *Lucy*, *Miss Frowd*, and *Empress Eugénie*. In the next best collection were excellent blooms of *Zerlina*, *Royal Visit*, *Alliance*, *Cynthia*, *Novelty*, *Alice*, *Rev. J. D. Horner*, *John Smith*, *Brunette*, and *Beauty of Cheltenham*. The class for twelve blooms was well filled, Mr. Dodwell was first with an evenly matched collection, and scarcely inferior was the next from Mr. Douglas. The best collection of six included *Miss Wood*, *Mr. Lord*, *Amy Lord*, *Morna*, and *Mrs. Summers*. For single specimens there was a numerous competition. For red heavy-edged varieties *Dr. Abercrombie* was the best flower, followed by *Princess of Wales*, *John Smith*, *Colonel Clerk*. Those with red light edges were Mr. A. Chancellor, *Violet Douglas*, *Emily*, *Mrs. Bower*, and *Thomas William*. Purples were represented by *Norfolk Beauty*, *Albance*, *Zerlina*, *King of the Purples*, with heavy edges; *Minnie*, *Her Majesty*, *Ann Lord*, with light edges. Rose or scarlet kind with heavy edges were represented by *Royal Visit*, *Lucy*, *Mrs. Payne*, and *Edith Dombain*; and the light-edged by *Mrs. Allerof* and *Miss Wood*. The class for blooms with yellow grounds included *Prince of Orange*, *Mrs. Frampton*, *King of Yellows*. The plants in pots consisted of *Carnations*—*Rose of Stapleford*, *Satisfaction*, *Illuminator*, *Falconbridge*, *Clipper*; *Picotées*—

Norfolk Beauty, Brunette, Rival, Purple, &c. A list of awards will found in our advertising columns.

Royal Botanic Society.—The 40th anniversary of this society was held the other day at the Gardens, Regent's Park, Lord Chesham in the chair. The annual reports of the council, auditors, and secretary were read. From these it appears that the society has passed through a much more successful year than, from the extraordinary weather, the council might have reasonably expected. New subscribers to the number of 115 had joined the society since the last anniversary, being three more than the number elected during the previous year, and also above the average. The receipts from subscriptions, under all items except that of life compositions, had also been larger, and those from the exhibitions reached a very fair average. Exhibitions of spring flowers and of summer flowers and fruit had been carried out with the success for which the society is famous, and special exhibitions of Rhododendrons by Mr. Anthony Waterer, and of annuals grown in pots by Messrs. Carter, had also been made. The latter were very useful, especially to the million whose domicile must necessarily be in towns, showing how much may be done in the way of getting a few cheering flowers on the window sill by the expenditure of a few pence for seeds and a little ingenuity in providing a pot, box, or pan in which to grow them. The secretary's report referred to the more technical if not the more popular objects of the society—namely, the study of botany in its relation to medicine, the arts, and manufactures. A total of 540 free students' and artists' tickets had been issued for terms of from one to six months each, and about 25,000 cut specimens given to them, and nearly 29,000 distributed to the several medical and art schools of the metropolis. A valuable consignment of plants and seeds had lately been received from the Government of Madras, including the Mangosteen, Nutmeg, and other economic plants, and seeds of the Teak timber tree, from which several healthy plants had been raised. Interesting additions have been made to the museum, including Olives grown at the Cape of Good Hope, and Coffee and Vanilla cultivated in Tahiti. The elaborate meteorological observations carried on in the Gardens for years, and the annual extracts published with the reports, were very useful for comparison, especially for extraordinary seasons like the present; from these extracts it appears that the mean of the readings for the first six months of this year gave a net mean temperature of 49.35, against that of last year of 54.7, and the rain for the same period an excess of nearly 3 in. Thus the work of the society, although carried on by private individuals at their own cost, may in many respects be looked upon as of national interest.

FRUIT AND DIARRHŒA.

As usual at this time of the year, deaths from diarrhœa are frequent, and the outcry against fruit is loud; for fruit in general, or stone fruit in particular, is charged with being a principal cause of this mortality. But, in spite of this, people will eat fruit, and will not be frightened out of doing so; for human nature declares more strongly in its favour than for any other article of food—the more unsophisticated the palate, the stronger is the attraction. Is the charge, then, true? Has our Maker made us with such a strong natural taste for that which is hurtful? The public do not seem to be sufficiently aware that fruit is a food, not merely a medicine or a luxury—a food, too, upon which it is possible to live entirely, and with the highest degree of health and strength. It is not unknown among us for individuals to live absolutely on fruit for twelve months at once, and get through an almost incredible amount of both sedentary and active physical work upon it. I have myself tested it in a comparatively small way by walking from Liverpool through Chester, Hereford, Ross, Gloucester, down to Bath, thence to London, and back through Bedford, Leicester, Derby, Buxton, and Manchester, to Liverpool again—a distance of above 500 miles, being an average of at least 35 miles a day for fifteen days, in very hot weather (of 1878), without taking anything either to eat or drink except in the shape of raw fruit. During this time I was three nights without getting to bed, two of which were in succession, making three days and two nights tramping at a spell; and yet I did not feel a bit jaded, but felt fresh to the last, so much so that the last day's walk (from Manchester to Liverpool) I did right off without a rest. This was straight from the confinement of an office, and by one of more than ordinarily sedentary habits. I ask, therefore, must there not be more nourishment, and that of the best kind, in fruit than it generally takes credit for? Yes, that may be all very fine, but the deaths from diarrhœa remain palpable and undeniable facts. Certainly, but I think those deaths can be rationally accounted for. As to eating stone fruit, I have eaten more of it in one summer than any than any of those are alleged to have died from it. Con-

sider how the fruit is eaten, and see if we cannot find a better reason there. It is commonly treated merely as a plaything for the palate, and eaten either between meals, or at the tail end of a meal, when people have had at least enough to eat already. Disagreeable effects are then complained of—and no wonder. For my part, considering the ill-assorted mixtures people take in the shape of food when well, and the mixtures they take in the shape of medicine when ill, I am astonished that there are not many more deaths. If people would cultivate simplicity of tastes with regard to their food, and let fruit form a regular part of their meals, they would find an increased pleasure therein, and we should no longer hear complaints about the unhealthiness of fruit.—E. S. HYATT, in the *Liverpool Daily Post*.

ARRANGEMENT IN WINDOW GARDENING.

It is a rather curious fact that the taste for window gardening often appears to partake of a local character. Whilst in some small towns and in many villages one sees almost every window more or less well furnished with flowering and fine-foliaged plants, in others but slight evidence is afforded of any great interest being taken in floriculture. This fact is rather difficult of explanation, as the opposite extremes may be met with in places but a few miles distant from each other. I am acquainted with a town in this neighbourhood where the love of flowers, if one may judge by the bare, plantless windows, must be at a very low ebb. A neighbouring village is as conspicuous in the opposite direction, most of the windows being filled with plants in good condition, some of the collections displaying considerable variety and exhibiting good taste in the arrangement. Where the taste for window gardening has become so developed it would probably be found that one or two individuals were at some time mainly instrumental in creating and fostering a love for plant culture. I am inclined to believe that lack of knowledge rather than want of taste will account for the bare, cheerless, flowerless aspect which many dwellings present the whole year through. It will generally be found that the cottage gardens in the immediate neighbourhood of a large well-managed private establishment are better kept and cropped than those whose owners never enjoy the advantages of witnessing the best methods of culture. Those who work or who have worked in private gardens, if only in the modest capacity of garden labourer, invariably grow better vegetables, and endeavour to beautify their dwellings to a much greater extent than the ordinary farm labourer or the mechanic. In the same way a well-furnished window in a town or village will stir the energies and excite the emulation of the inhabitants generally; consequently, those who devote both time and pains to the task of beautifying their dwellings with Nature's floral treasures may have the satisfaction of knowing that they may be the means of encouraging others to go and do likewise. I have, I fear, wandered somewhat from the subject upon which I would wish to make a few remarks viz., the arrangement of plants in windows. Professional gardeners are fully aware of the importance of skilful grouping; in fact, in the present age of extensive floral decoration, plants have to be grown either naturally, possessing the various forms necessary for producing graceful effects and pleasing continuations, or they must be trained in a manner best calculated to fit them for the purpose for which they may be required. A few days since I remarked a window garden so pleasingly and effectively arranged as to present a marked contrast to all others in the vicinity. The plants were of the ordinary description, but they were evidently chosen as being more suited for the place. Not only did they exhibit signs of painstaking culture, but the arrangement showed an intelligent appreciation of the good effects to be produced by judiciously intermingling such plants as vary considerably both in form and colour. The form of arrangement will naturally depend upon the shape and aspect of the window. Those windows which project slightly from the dwelling best admit of tasteful grouping being carried out in them; but in almost every dwelling space enough will be found to allow of taste and judgment being exercised. Although no arbitrary rules can be laid down for plant arrangement, yet some general instructions may be given which may prove of service to the inexperienced. In the first place no window can be considered well furnished unless it contains graceful drooping plants suspended in a basket. Some of the plants best fitted for window culture lend themselves well to this treatment. Some, such as the Wandering Jew Saxifrage, are of extremely easy culture, and a well-grown specimen, with its pendulous offsets drooping down and intermingling with the other inmates of the window, certainly presents a very attractive appearance. The common Musk, again, displays itself to greater advantage when grown in this manner. Then we have such plants as *Russelia juncea*, *Dracæna vivipara*, *Panicum variegatum*, and many beautiful kinds of Ferns, which thrive admirably in such situations, and with good attention

will last in beauty for an indefinite period. Tropæolums, Maurandias, Lophospermum variegatum, Cobæa variegata, and Ivies may also be cited as especially suitable for the purpose. My intention is, however, rather to indicate the description of plants needed than to give a list of kinds, as the grower will, in the course of his experience, meet with a number of graceful-habited subjects well adapted for this mode of culture. In this matter the grower will also need to select his subjects according to the aspect of the window; a Fern, for instance, will thrive admirably in a north aspect, where a Tropæolum would give but little satisfaction, and *vice versa*. The central object in the arrangement should be a foliated plant of some kind distinguished for its graceful habit and for its verdure. Where there is space nothing is more suitable than a Palm, the more hardy kinds of which may be kept for several years in health in a small pot without materially increasing in size. If there is not space enough for Palms then some of the many forms of Dracenas may be selected, or a Grevillea, or Acacia, or any kind of slender-stemmed, upright-growing foliated plant. This, together with one or more kinds of Ferns, and a pot or so of the fresh green Selaginella, will give plenty of verdure; and if the flowering plants be judiciously selected with respect to height, habit, and colour, and the whole arranged with an eye to general effect, the result will be very pleasing. Where there is space, more than one basket may be suspended. In the window already alluded to there were three—a Tradescantia zebrina in the centre flanked by a fine Musk specimen and Panicum variegatum. The three essential points to be arrived at are a judicious blending of colour and verdure, and a tasteful disposition of the various subjects employed. I have been induced to offer these few observations as I have noticed a general tendency to crowd together a number of flowering plants, thereby creating a blaze of colour. This is all very well as far as it goes, but it does not realise the ideal of window gardening, which, in addition to skilful culture and variety of subject, should certainly include good taste in the general arrangement.

Byfleet.

JOHN CORNHILL.

ANSWERS TO CORRESPONDENTS.

Diseased Fruit.—I have sent you some Figs and leaves of a Chaumontel Pear tree. The Figs are a large crop, but many of them are curled like those sent, and during the last two or three weeks have been dropping off, having spots of decay at the eye. Has the weather caused the mischief? The leaves of my Chaumontel Pears shrivel as if burnt by frost about the time when the first shoot is about 6 in. or so long. It does not affect the growth of the trees, and the fruit grows to perfection. Other Pear trees in the same position are not affected. The Fig trees are standards, and always ripen their fruit well. I observe that the White Genoa Fig, which is much earlier than the Brown Ischia, is not affected in the same way, but has not so abundant a crop this year.—E. T. R. [We cannot give you any explanation of your curled and mildewed Figs, but we think you are right in referring their unsatisfactory condition to the abnormally wet and cold season. The common moulds now on the fruit are quite a secondary symptom. In reference to the Chaumontel Pear leaves, it is singular that they should be badly affected and the fruit, as you say, grow to perfection; we are, on this account, inclined to refer the black and discoloured leaves to the action of frost on the very young foliage. We can see no fungus, and had there been fungus at an earlier stage of growth it would, doubtless, have attacked the fruits also.—W. S.]

Arundo conspicua.—When may I clip this (as I do yearly the Pampa Grass)? My plants of it are full of semi-dead leaves, alive at the base, and so not to be pulled. I once clipped an Arundo in early spring, and it took two years to recover, but I am sure if done at the right time they would make greener and tidier plants.—J. H. W. T. [If you clip your plants at all do it in spring, just before they begin to grow. They will require the rough foliage as a protection in winter.—G. W.]

Paraffin. B.—We would not recommend you to burn this in a Vinery in which Grapes are ripening. A house 18 ft. by 12 ft. might easily be heated by means of a fire-clay pipe-flue. M. J.

Guano.—A handful for every 2 sq. yds. will be enough. If used in a liquid state put a 3-in. potful into an ordinary watering-canful of water. Such stimulants should be used weak and often rather than in the form of strong doses. J.

Cabbages.—Your plants are clubbed, the work of an insect, the larvæ of which you will find in the tubercles. Clubbing generally begins in the seed-beds, and care should be taken, when planting, to reject all clubbed plants. Remove at once all that are affected and burn them. When the crop is off the ground give it a good dressing of lime and soot, and trench it deeply, letting the next crop be one not liable to club.—M.

The Edelweiss.—Can you inform me how this is cultivated? Will it do best on a rockery planted in peat?—D. S. [It will succeed in any ordinary border which is exposed and well-drained. The soil should be rather light and rich, but peat is not absolutely required. Seedling plants should be grown on in frames previous to being planted in the open border.]

Names of Plants.—J. C. N.—Lilium Martagon. W. P.—1, Liatris spicata; 2, Calceolaria amplexicaulis; 3, Spiræa Ulmaria; 4, S. sorbifolia. M. T.—Solanium crispum. P.—1, Echinacea purpurea; 2, Gymnogramma chrysophylla; 3, G. tatarica. M.—Aster Tripolium. E. C.—Campanula fragilis; the other is Linaria Cymbalaria. Lady C.—Cerinthe aspera. *Gramineæ*.—Probably Stipa pennata. F. C.—1, Echinacea purpurea; 2, Hibiscus Trionum; 3, Campanula fragilis; 4, Davallia Mooreana. S. J.—1, Asclepias syriacus; 2, probably Campanula pyramidalis. M. J.—1, Sprea palmata; others next week. G.—1, Liatris spicata; 2, Anemone rivularis; 3, Enothera frutescens; 4, Sedum Aizoon. Mrs.

N.—1, Gentiana cruciata; 2, Sedum dasyphyllum; 3, Primula Dinyana. H. E.—1, Alstroemeria oculata; 2, Magnolia glauca.

Questions.

Granadillas (Passiflora quadrangularis).—Can any one tell me what is the best way of using these as table fruit; also how long they will probably take to ripen, being now green and about as large as a hen's egg.—SOUTH SOR.

Saxifraga Wallacei.—Is this Saxifrage, which is reported to be one of the finest grown, a species or variety? If a species will some one be kind enough to give its history, whence introduced, &c.? I have seen the plant, and it appears to belong to the palmate division, but in my opinion there are far handsomer Saxifrages in the same group, such as S. Rhei, Mawi, ceratophylla, geranioides, and ajugefolia.—THOS. WILLIAMS, Ormskirk.

Air-roots of Vines.—1, When air-roots appear from the eyes of Grape Vines are they signs of vigorous growth or mismanagement? 2, Are they detrimental to the full development of the fruit? 3, By what cause are they produced?—M.

Salvia patens.—I have several plants of Salvia patens in my garden this year, and though they have all grown vigorously, few blooms have come to maturity, having dropped off in the bud state. Will any of your readers kindly give me the reason for this?—W. J. T.

Walks.—Being informed that limestone chippings would set and make clean walks I tried them and find that they will not set. Is there any way of making them solid, short of asphalt?—F. D.

AMERICAN NOTES.

Squash Jam.—It is amusing to find English horticultural journals discussing the question of jam from the Vegetable Marrow, which is, in England, a poor substitute for our squashes. One writer says, that for the production of jam, "the Vegetable Marrow stands unrivalled. . . . The white-fleshed Marrow naturally produces the palest jam, but the flesh of the darker kinds, especially that of the Ohio squash (whatever that may be), not only produces the richest colour in the preserve, but also the best flavour." The same writer adds, "Much depends upon the making." A remark that applies equally to stone soup. We have known preserves to be made from Tomatoes and sngar, and have even seen people eat them, as if they liked them—but squash jam!

The Moss Pink in America.—One of our best native early-flowering plants, Phlox subulata, has rewarded an English amateur, Mr. Nelson, who has raised from seed a number of varieties as regards colour. THE GARDEN says, "It would be interesting to know if there are many varieties where the plant is common in America; if not, our American friends will have to come to us for these." Of course we do not know the extent of the variation obtained by Mr. Nelson, but we have this charming plant, in the purest white, deepest rose, with numerous intermediate shades, and all excellent.

The Ailantus.—The *Tribune*, in common with other American papers, has had its annual denunciation of the Ailantus as a street tree. It sets forth in language strong and truthful the fact that the unpleasant odour which the flowers possess quite unfits it for being planted near dwellings. It says, "Everybody knows it as a street tree, where it is a nuisance unmitigated save by the single fact that it does not harbour worms or insects, because no self-respecting worm can be induced to approach it." The truth of this assertion rests upon the self-respecting character of the insect, or "worm." We never knew Entomologists, who are supposed to know insects morally as well as structurally, to charge Saturnia cynthia with any want of "self-respect," yet that has such a decided preference for the Ailantus leaves over all other food, that it has received for this reason the popular name of "Ailantus Silk-worm." This insect, by the way, has become quite naturalised in parts of Brooklyn, and in some streets the trees are, or were a few years ago, a greater nuisance on account of the "worms" which they harboured than because of their odour. Besides, other insects do feed upon the Ailantus.—*American Agriculturist*.

Rich Soil Best for Hardy Ferns.—I am inclined to think that many of our hardy Ferns would be thankful for a more generous diet than is generally accorded them. This season a plant of the common Hart's-tongue was planted in pure night soil, with the effect of inducing an exceptionally vigorous growth. The good effects of the rich food are, however, more observable in the exceptionally deep lustrous hues of the fronds. The Scolopendriums especially would be benefited by a liberal admixture of rotten manure added to the soil when planted, and established specimens should be well mulched with it early in the spring. They would also undoubtedly be benefited by saturation of weak guano water in hot weather. Many of the smaller-growing species which require to be placed in a very free sandy compost would, I am assured, feel the benefit of a little extra nutriment when in full growth.—J. C. B.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTES OF THE WEEK.

The Reports on the Fruit Crop elsewhere printed in this week's issue are not very encouraging. They tell of sad disasters to Apricot trees owing to the remarkable season which we have experienced. Branch-dying has been unusually prevalent, and many trees have died outright. Peaches and Nectarines have suffered greatly from blister, and so backward are their fruits that in many places they will never ripen. Pears, though in some cases rusty and cracking, are better this year than Apples, which are generally a thin crop, and the fruit still keeps dropping from the trees. The latter, too, are in some places almost leafless. Cherries, with the exception of Morellos, cracked and rotted on the trees. Even as far north as Durham, the Morello has been better on standards than on walls, a fact worth noting, seeing that, in addition to its fruit, the growth of the tree itself is highly ornamental. Damsons are everywhere reported to be good, and in some places even heavy crops. Next to these stand Victoria and the Orleans, Plums that seldom fail. Nuts are good in many places, but Walnuts are a failure. All small fruits have been heavy crops, but flavourless; and Gooseberries have been in many places stripped of their leaves by the Gooseberry caterpillar. Of little known fruits, Helena Gloede Strawberry is spoken of as being a valuable late kind, and Stone's Apple, a local Kentish variety, is reported as being a sort that well deserves more extensive cultivation than it has hitherto received. Worcester Pearmain, a beautiful Apple, is also stated to be good. For other matters of interest to fruit growers we must refer to the reports themselves.

A New Montbretia (M. Potts).—Few more valuable additions have been made of late years to our list of hardy bulbous plants than this beautiful Montbretia. It was, we believe, introduced to the notice of cultivators by Mr. Potts, Fettes Mount, Lasswade, in compliment to whom it is named M. Potts. As there are but few Montbretias in cultivation, it may be well to mention that they are nearly allied to the Gladioli, and the plant under notice is similar in appearance to some of the small-flowered species. It grows from 2 ft. to 2½ ft. high, and bears abundance of bright green leaves, which resemble those of a Gladiolus, both in form and in their singular plaited appearance. The flowers, which are conical, have the tube slightly curved. They are about 1 in. long, and ¾ in. across the mouth, and are borne on branching stems, each branch bearing as many as three dozen closely-arranged flowers. Their colour is a bright orange-red with spots of a darker hue inside the tube, colours which when seen in profusion render the plant highly attractive either out-of-doors or in the greenhouse. It is now finely in flower at Kew, and also in Mr. Ware's nursery at Tottenham, associated with its pretty congener *M. rosea*, which is also just now producing an abundance of delicate rosy blossoms.

Torrey's Solanum (S. Torreyanum).—This extremely rare hardy perennial is now in flower at Kew. It is of dwarf habit, growing not more than 1 ft. high, and has rather large leaves, sinuated at the margins like those of the common Oak. The flowers are produced in loose terminal clusters, and are about 1 in. across, of a lilac-purple tint, and the central tuft of stamens is bright yellow. It succeeds well in the ordinary border, and when better known will be a capital plant for a front position in a mixed border. It is a native of North America, but its exact habitat we have been unable to ascertain.

Aster Townshendi.—This is a fine addition to Michaelmas Daisies, and one that will doubtless, when better known, gain public favour. It is nearly allied to *Aster canescens*, which is known also under the generic name of *Machæranthera*. It grows from 1 ft. to 1½ ft. high, and is robust and much branched in habit, with the root-leaves from 8 in. to 12 in. long, oblong, rounded at the tips, and sharply toothed at the margin. The upper leaves are stem-clasping and somewhat heart-shaped. The flower-heads, which terminate all the branches, are from 2 in. to 3 in. in diameter; the central florets form a bright yellow eye; the others, which are arranged in two rows, are narrow and about 1 in. long, and of a bright violet-blue. It is perfectly hardy and perennial in duration. It is a native of the Rocky Mountains of Colorado, from whence seeds of it were first sent to Kew about two years ago. It is now finely in flower in the open border in Mr. Ware's nursery at Tottenham.

The Long-flowered Primrose (Primula longiflora).—We saw a very distinct and handsome plant bearing this name in flower a few days ago in the Kew collection. Its leaves are lance-shaped, from 3 in. to 4 in. long, and covered with a white mealy substance on the under surface. The flower-stem is from 4 in. to 6 in. high, and is also invested with farinaceous matter, and terminated by a cluster of blossoms the tubes of which are fully 1½ in. long, of a reddish-brown colour. The petals measure ¾ in. across, and are of a rich deep purple tint, with a yellowish centre. Whether this be the true *P. longiflora* of Allioni or not we are unable to determine, as the nomenclature of Primroses is somewhat in a confused state. It is, however, a very desirable plant on account of its distinctiveness.

Odontoglossum vexillarum multiflorum.—A unique variety of this fine Orchid is now in bloom at the York Nurseries. It has ten blossoms on one spike: eleven were formed, but the first perished by an accident. The individual flowers are above the average size, and are of a fine clear "self" pink. Though vigorous as a plant, this variety is scarcely larger in bulb than other well grown specimens which have produced six and occasionally seven flowers on a spike.—J. BACKHOUSE & SON, York.

Sedum trifidum.—This interesting and rare Stonecrop is now finely in flower in the frames of Chiswick. It is about 6 in. high, and has slender, erect, and unbranched stems. The leaves are oblong and coarsely toothed, and are collected in a cluster on the upper part of the stem, and surround a dense cluster of deep rose-tinted blossoms, which are about ¾ in. across. It is a pretty plant for growing on rockeries, and apparently is not at all difficult to manage. It is a native of the Himalayas, where it grows plentifully on rocks and trees.

Fine Mexican Lælia.—By far the deepest coloured Lælia of any species that we have ever seen is now flowering in our collection. It is apparently a variety of *L. autumnalis*, and may well bear the name of *atro-rubens*. Dark purple-crimson most nearly describes the colour of the buds, and the expanded flowers are only a shade lighter. The large side lobes of the labellum being white, the contrast is charming. Five flowers are borne on the stem. We received it from our collector in Mexico last autumn.—JAS. BACKHOUSE & SON.

Hyacinthus candicans.—This beautiful bulbous plant is now very effective at the Hale Farm Nurseries, Tottenham. Its flower-stems, which rise from 3 ft. to 5 ft. high, are each terminated by a pyramid of pure white bell-like flowers, which, owing to their firm substance, last an unusually long time in beauty. It is reputed not to be hardy, but plants of it that were subjected to the effects of the past winter are now looking healthy, though not so early as those which were taken up and protected.

Fine Cherries.—Four varieties of Cherry have been sent to us by Mr. Rivers of Sawbridgeworth which well show the remarkable improvement which has lately taken place in these fruits. Two are white and two black, and of the four the white sorts are the best as regards flavour. Of the black kinds one is the late Black Bigarreau, a large handsome fruit, the other Bigarreau Noir de Schmidt, a fine kind to which a first-class certificate was awarded by the Royal Horticultural Society in 1872. Of the white kinds one named Bigarreau Gros Cœur is stated to be synonymous with Belle de Roemont, an abundant bearer and a very useful Bigarreau; the other is Bigarreau Monstreuc de Mezel, a very large and handsome Cherry, by no means new, but not so well known as it should be. These Cherries are the produce of orchard-house trees.

Diuris lilacina.—We have received from the New Plant & Bulb Co., Colchester, flowering specimens of this interesting Australian terrestrial Orchid. It is a slender-growing kind, with stems from 1 ft. to 1½ ft. high, furnished below with several grassy leaves, and terminating in a loose raceme of pretty flowers. The segments of the flower are broad, and of a pale purple hue above, deepening into a darker shade at the base; the tip is heart-shaped, rich chocolate in colour, and surmounted by a golden crest. The two lateral sepals are prolonged into narrow, greenish tails, which give the flower a singular appearance. There are many other kinds of terrestrial Orchids in Tasmania and the temperate parts of Australia which far excel in beauty those from corresponding latitudes of the northern hemisphere, and which would well repay introducing, as they would undoubtedly soon become popular.

Vase Decoration at Kew.—The numerous vases dotted here and there amongst the flower beds in front of the Palm house at Kew afford ample illustration as regards what one should avoid in selecting and arranging plants for furnishing vases. Those employed at Kew are, for the most part, so ill-adapted for the purpose that even in favourable seasons the effect produced would have been but indifferent. The proper use of vases in garden adornment is here apparently lost sight of. Instead of filling them with such plants as have long trailing stems that would hang gracefully over the rims,

and allowing the centre to be occupied by bold plants of an elegant character, such rigid-looking subjects as *Agave americana* are made free use of, and some are even furnished with half-starved *Gasterias* surrounded by small plants of *Echeveria glauca* arranged in a dense, cushion-like manner. The huge vase which terminates the main walk, one of the noblest of garden promenades, is conspicuous only for the heap of paltry rubbish with which it is filled. The inevitable American *Agave*, which occupies the centre, is almost smothered by a few common *Petunias* and similar plants, which would not be tolerated even in a third-rate villa garden. Considering the unequalled resources at Kew, the flower vases ought to constitute the leading feature in the flower garden, and a walk through the adjoining houses would suggest a host of beautiful plants with which to fill them. For instance, what could be more suitable for such purposes than the elegant hardier kinds of *Cordylines*, *Dracenas*, *Dasyliirion*, *Yucca*, *Fourcroya*, *Palms*, *Canna*, *Astelia*, as well as *Puya* and other *Bromeliads*, the *Pandanoid Eryngiums*, *Doryanthes* excelsa, and many other beautiful subjects which would thrive admirably during half the year? Plants of a gracefully drooping habit for embellishing the outside of the vases are equally numerous, and would be as easily managed as those now used.

Spikenard of the Ancients.—Amongst the many interesting plants now in flower on the rockery at Mr. Ware's nursery at Tottenham, is a mass of this Valerianaceous plant imported from Nepal. It is identical with that named at Kew as *Nardostachys Jatamansi*, the root and young stems of which, before the leaves unfold, are said to have constituted the Spikenard of the ancients. It is a perennial herb with lance-shaped root leaves. The flower-stems are from 3 in. to 6 in. long, terminated by a cluster of small and not very attractive violet-coloured blossoms. The upper parts of the roots are furnished with a fibrous covering, the remains of the past leaves. The perfume of the bruised roots is considered agreeable by some, whilst to others it is decidedly unpleasant. It is a highly interesting plant, and one which is quite amenable to culture in the ordinary border or rockery.

The Large Vinery at Chiswick.—This spacious structure is now one of the most interesting features in the Royal Horticultural Society's garden. It is one of the largest houses of the kind devoted entirely to Grape culture, being 180 ft. long and 23 ft. wide, and it has a curvilinear span roof of a proportionate height. Now that the Vines are heavily laden with an abundant crop of Grapes, which already show signs of ripening, the effect of the thousands of bunches is very striking. A large and varied selection of varieties is grown, and it is interesting to observe how the majority of them thrive in one house and under the one mode of treatment.

Transplanting Old Rose Trees.—During last winter, and even late in the spring, we transplanted most of our Roses, principally dwarfs, but some standards, and amongst them many that were old and apparently worn out; some, in fact, were put in more for experiment than with any hope of good results. Our soil is a stiff loam, and we gave it a thorough dressing of rich farmyard manure, trenching the ground first, and then forking the manure into it lightly before planting. Many of the dwarfs had not a single fibrous root, and, as we separated them with a sharp spade, they were more like cuttings than rooted plants; so we inserted deeper than they were planted before, in order that they might make fresh roots from the collar of the stem. Owing to the lateness of the season, and their having to make fresh roots, they were late in starting; but they have all produced some very fine high-coloured blooms, and, favoured by the dripping season, have kept very clean. Being now divested of their first crop, they are showing abundance of buds for autumn blooming, and sending up such shoots from the base as to indicate the certainty of plenty of fine bloom next year. I would therefore recommend any one having Roses in an unsatisfactory condition to transplant them in the autumn before the heat of the ground declines too much, as I feel assured that they will be well satisfied with the result. We grow Roses principally for indoor decoration, and find dwarf plants preferable to standards. In pruning we cut a good portion of the old wood, and leave the strongest young growths, which, when pegged down, flower their entire length.—J. GROOM.

The Weather and Bedding Plants.—As a proof of the cold temperature that has prevailed this summer, *Coleus Verschaffelti*, bedded out here in June, has almost entirely disappeared, having literally "melted away."—J. H. W. T., *Co. Carlow*.

The Time of Roses.—Kindly correct an error and supply an omission in the article which you have quoted from *Time* (p. 140); Mr. Cant's address is Mr. Benjamin R. Cant, Colchester; and in my list of select Roses I have omitted, I suppose on the principle *cetera va sans dire*, the beautiful *Marie Baumann*.—S. REYNOLDS HOLE.

THE INDOOR GARDEN.

THE HARE'S-FOOT FERNS.

THOSE Ferns included in the genus *Davallia* that are characterised by having their creeping rhizomes clothed with chaffy or silky scales are popularly known as the "Hare's-foot Ferns," on account of the resemblance which the growing points of their rhizomes bear to the divisions of the hare's foot. The section comprises twenty-one species and several varieties, which are somewhat local as regards geographical distribution. They are all confined to the Old World, predominating in Eastern Asia and Polynesia; only one species is indigenous to Europe, and one to New South Wales. Most of the dwarf species are epiphytal in habit, and those that are terrestrial are found in situations where their rhizomes are placed beyond the reach of stagnant moisture; they are usually found growing on the dry mounds formed by the enlarged bases of forest trees.

Hare's-foot Ferns are all easily cultivated, and under suitable conditions soon make good specimens. The readiest means of propagation is dividing the rhizomes, as their spores seldom germinate. They require good drainage, and to be grown in a mixture of turfy peat and sand. Those with wide-creeping rhizomes make fine objects when grown upon domes of peat, and they also answer well for covering walls and Tree Fern stems, and for furnishing baskets. The larger-growing species, which have short-creeping rhizomes, do best in broad, shallow pans, with the soil elevated in the centre, so as to place the rhizomes upon a well-drained surface. In order to form a dome of peat to be covered by some of the scandent species, a pan about 20 in. wide and 9 in. deep is necessary. Let one-third of its depth consist of drainage, and let the remainder be filled to the surface with turves of peat packed as tightly as possible; upon this pile more turves up to the height required. Then drive a few short stakes through the turves into the firm foundation within the pan. The outside can then be trimmed into shape. Upon the surface of this plant a sufficient number of rooted pieces to fairly cover it, and keep the young growths pegged in. The dense matrix which will be afterwards formed by the roots sent down from the increasing rhizomes will assist in holding the dome together, and will keep it in good condition for several years. In order to cover walls and rough pillars, it is only necessary to plant several well-rooted pieces at their bases and to keep them moist by occasional syringing. Tree-Fern stems may be covered in a little time by fixing plants on them at different heights, and by covering the rooted portions of the plants with moist *Sphagnum* until they are established. All the species of this section are interesting, but, as the majority of them closely resemble each other, the following are selected on account of their being individually distinct and worthy of special notice.

D. divaricata.—This is also known as *D. polyantha*. It has a stout, short, creeping rhizome clothed with brown shaggy scales. The fronds grow from 3 ft. to 5 ft. in length, and droop very gracefully; they are tri-pinnate and have from six to eight pairs of lateral pinnae and a terminal one, which is much the largest. When first produced the fronds have a rosy tint changing to a reddish-brown colour, which is retained by them until they wither. It is a native of the Malayan Peninsula and Java, and requires a stove temperature and plenty of light.

D. elegans is a more erect-growing plant than the foregoing, and has considerably more substance in the fronds. The rhizomes are covered with linear brown scales, and the stripes, which are chocolate coloured, are highly polished, a circumstance which makes a fine contrast with the olive-green of the foliage. The fronds are triangular in outline, and attain the height of from 2 ft. to 3 ft. The pinnae, which are very glossy, are cut into finely-divided, oblong, toothed segments, and slightly overlap each other. *D. elata*, one of

the varieties of this species, is more coriaceous than the type, and is a much taller-growing plant, with more distant pinnae, and its foliage retains its freshness for two or three weeks after being cut. Both species and variety are common throughout Polynesia and Tropical Africa, and they require the same treatment as *D. divaricata*.

D. solida.—This is the most luxuriant of the series. The fronds are of a fresh green colour, and are copiously produced from a wide creeping rhizome, which is sparingly clothed with dark brown scales. They are tripinnatifid, and are cut into deep wavy lobes, giving the plant the appearance of a large Killarney Fern. It is a native of the Malayan Peninsula and Polynesia, and requires a stove temperature.

D. pallida.—The well-known Fern cultivated under the provisional name of *D. Mooreana* was named by Mettinus *D. pallida*, previous to its introduction to our gardens; therefore the oldest name should have the preference. It is readily distinguished from all the others by its yellowish green colour and its round segments. It closely resembles in habit *Leucostegia immersa*, which latter is often sold as a substitute for it. It prefers soil containing a good proportion of loam, and requires more water than most *Davallias*. It should have an abundance of light, and it makes an attractive basket plant. It is a native of Aneiteum.

D. canariensis.—This is commonly known as the true Hare's-foot Fern. It has stouter rhizomes than those of any of the genus, and they are covered with close-pressed acuminate scales. The fronds are deltoïd, and are cut into numerous linear segments; they are also deciduous, sometimes shedding them twice in the year. In the south of Spain it is met with commonly growing on the trunks of the Cork Oak, insinuating its rhizomes among the rugged fissures of the outer bark, and apparently drawing its nourishment from the humus formed by the decay of leaves and mosses. It annually requires a season of rest, and should be kept moderately dry from the time its old fronds begin to fade until the young ones appear. It requires plenty of air and light, and being a native of Spain and the Canaries, it should be treated as a temperate house Fern. It thrives well in dwelling rooms.

D. fijiensis.—This comes very near in character to the preceding, but it is far more beautiful; the rhizomes are smaller and more regular, and produce a greater abundance of fronds, which are ever-green, and much more finely divided. It grows very freely, and is without doubt one of the most elegant Ferns in cultivation. It is at present very rare in collections, though it is one of the commonest Ferns of the Fijis.

D. bullata.—Although this is an old inhabitant of our stoves, it is still a great favourite. It grows rapidly, and supplies an abundance of fronds for cutting; the rhizome is wide-creeping, and clothed with spreading scales; the fronds, which are triangular, are from 6 in. to 12 in. in length, and taper off into long points; the pinnae are glossy and slightly recurved. It is a native of Japan, Hindostan, and Java, and is suitable for an intermediate house.

D. dissecta.—In general appearance this resembles *D. bullata*, but it is more robust, and grows even more rapidly. The scales on the rhizome are of a darker colour, and the fronds are larger and of a firmer texture. It is a native of Japan.

D. pentaphylla.—Were it not for the marginal sori of this Fern, there would be some difficulty in recognising it as a *Davallia*, so much does it differ from that genus in character. The rhizome is wide-creeping, and covered with spreading, bristly scales; the fronds are simply pinnate, with from two to three pairs of lateral pinnae, and a terminal one; in texture the pinnae are coriaceous, and are of a very dark green. It is a native of Polynesia.—C. M.

Anguloa eburnea.—I see that Mr. Baines, writing upon the treatment of this genus, enumerates amongst others *A. eburnea*; now I have frequently heard this plant spoken of and seen it described, but have never met with it. Can Mr. Baines or any of your readers enlighten me? What size are the flowers? what shape and what colour? I know it should be ivory-white, but that is no description. I am doubtful if the true plant is really in the country.—Z.

A Good Flue.—Mr. Epps has lately called our attention to the merits of a well-made flue. It keeps out frost and does not excite Heaths and hard-wooded plants when growth is not wanted. A good flue and good draught gives a dry, sweet heat, drives fungus away, and is better for some classes of plants than any hot-water apparatus. It is also more simple in action than most of these, and not so apt to get out of repair. We believe many amateurs with one or two houses would find a well-made flue to be by far the best mode of heating.

TREES, SHRUBS, AND WOODLANDS.

The Beech as a Shelter Tree.—Writers on forest trees have sometimes dwelt upon the immunity of the Beech from destruction by lightning, and on this account it has been recommended for planting as a shelter for cattle either singly or in groups in exposed situations. That this idea was for a long time prevalent we have abundant evidence from both ancient and modern writers. Never having myself seen an instance of its being struck, I was in 1875 strongly recommending it to a gentleman in the west of England, who was planting a park on high ground, and in which I had often seen both the Oak and the Ash shattered, when he informed me that he had just returned from Ireland, where, during his tour, he had found the public road stopped, and the further progress of his carriage barred, by a Beech tree which had just been struck down. Perhaps some contributors of *THE GARDEN*, who have witnessed similar occurrences, will give your readers the benefit of their observations. If, as a rule, the Beech is really entitled to the exemption claimed for it, this must be owing either to the conformation of its branches or its perfect non-conducting powers. Blencarn says:—"In hot countries, where thunderstorms are particularly alarming, the Beech has never been known to be struck by lightning."—A. J. B.

The Conservation of Woods.—The following from Evelyn may be interesting to our readers: "It were to be wished that our tender and improvable woods should not admit of cattle, by any means, till they were quite grown out of reach; the statutes which connive at it in favour of custom, and for the satisfying of a few clamorous and rude commoners, being too indulgent, since it is very evident that less than a fourteen or fifteen years' enclosure is in most places too soon, and our most material trees would be of infinite more worth and improvement were the standards suffered to grow to timber, and not so frequently cut at the next felling of the wood, as the general custom is. I am advised by such as are every way judicious and of long experience in those parts (the forests of Dean and Sherwood), that to enclose would be an excellent way, but it is to be considered that the people, viz., foresters and borderers, are not generally so civil and reasonable as might be wished; and therefore to design a solid improvement in such places His Majesty must assert his power with a firm and high resolution to reduce these men to their due obedience, and to a necessity of submitting to their own and the public utility."

Present Appearance of Woodlands.—The somewhat dull uniformity of colour which generally prevails in the woodlands throughout the latter part of June and the beginning of July becomes broken after the middle of the latter month by the midsummer shoot, which has during the present summer (still by courtesy so-called) not made its appearance until August, and very sparingly even now. Here and there a few branches on the Oaks and Elms have assumed a brighter green colour, and the bunches of Ash-keys, the cylindrical catkins of the Hornbeam, and the elongated catkins which form the embryo-spiked clusters of the Spanish Chestnut are on all sides conspicuous. The latter tree is now particularly striking as seen in the distance standing out in bold relief against dark masses of Oak, Elm, and Beech. The spreading form, though somewhat meagre in outline, of the Plane is also distinctly traceable against the dense and dark heads of Sycamores behind. Even the gigantic Walnut, which in winter was admired for the endless ramifications of its branches, and in the late spring for the warm russet or brown hue of its young leaves, is now one mass of the richest green, which appears almost unmoved by the high wind which is tossing the branches of the Beech trees, and wildly rocking the Silver Firs and towering Poplars behind it. Every season hath its peculiar beauties; and in the woodlands, where up to nearly the present time the colours of the foliage have been converging upon the almost universal dark green, they will soon rapidly diverge, until they melt away into the gorgeous hues of autumn.—A. J. B.

OBITUARY.

We have to record the death of Mr. John Weeks, an event which took place on the 13th inst., at Temple Dinsley, Hitchin, where he has resided since his retirement from business some ten years ago. Mr. Weeks was one of the oldest and best known of our horticultural builders, and one who in his time has effected many important improvements both in warming and constructing glasshouses. As the name of Weeks in connection with heating and hothouse building is world-wide, we think it well to mention that the business now carried on under that name will not be in any way affected by his death, inasmuch as he has ceased to take any active part in it since the year 1869.

THE FLOWER GARDEN.

New Zealand Flax in Flower.—It may interest some of your readers to know that *Phormium tenax* is flowering in South Devon this summer. Two plants, fourteen years old, which have never previously thrown up flower-spikes, and one of which was moved this spring, are now blossoming here, and last week I saw several in bloom at Dawlish. I am of opinion that this unusual circumstance must be attributed to the excessive rainfall of the last sixteen months, as it cannot be owing to abnormally high temperature during the last or the present summer.—A. PARRY ROGERS, *Stoke Fleming, South Devon.*

Candytufts in Wet Seasons.—The great value of Candytufts as mixed border plants I experienced for the first time this year. The seed was sown last March in patches about 4 ft. apart, along the side of a gravel walk, and its produce is now the chief ornament of my garden. I had intended to make some more sowings about the end of May between the patches, to do duty in their stead for the latter half of the summer season, and to remove the first-sown when their beauty began to fade. But this has proved to be needless; their beauty has been prolonged, and they promise to occupy the ground advantageously till the season ends. They are of all shades of colour, from pure white to deep purple; but when seen at a distance their prevailing tone is that of a rich lilac-pink. Of course it is impossible to tell at the commencement of the year what sort of weather will prevail in the coming summer, but it would appear that in a light and rather rich soil this annual is able to set at defiance a long continuance of rain and cold.—B. S.

Plants not Named at Kew.—In a botanical garden one naturally expects to find all the plants cultivated therein correctly and distinctly labelled. I was therefore much surprised to observe that what I and probably many other visitors to Kew would consider one of the most interesting collections of plants had no names affixed to them. I allude to the beds of Succulents in the vicinity of the large Palm-house. These beds are very interesting, inasmuch as they contain the greater portion of the Succulents now so popular and so extensively used for summer bedding, and enable visitors at a glance to compare their different habits of growth, thus enabling them to form an accurate idea of their capabilities for various purposes. The value of the arrangement is, however, completely marred by the absence of labels, which fact is the more unaccountable as common bedding *Pelargoniums*, *Verbenas*, &c., are all distinctly named. I may be informed that duplicates of these Succulents exist in the glass structures with names attached to them; but Kew is a large place, and, owing to the late hour at which the gardens are opened, there is really not time to thoroughly inspect every part of them in a day. The idea of thus grouping these Succulents in the open air is a good one, but omitting to name them must be considered a serious mistake, and has undoubtedly caused considerable disappointment.—J. CORNHILL, *Byfleet.*

The Day Lilies.—Amongst the various plants flowering just now in the herbaceous borders the *Hemerocallis* are specially noteworthy. They seem to luxuriate in the moisture which we are having, developing their magnificent and ample foliage in the greatest perfection, and upholding noble spikes of inflorescence which are very attractive. The double-flowered variegated *H. Kwanso* is one of the most effective: its ample foliage, distinctly striped with white, almost rivals that of the lovely *Pandanus Veitchii*. This is unquestionably a noble border plant, and one which should have an abundance of space in which to fully develop its proportions. The variegated variety of *H. fulva* is also a good border plant, somewhat less vigorous than *Kwanso*. These lifted and grown in pots are admirably adapted for decorative purposes. The double-blossomed variety of *H. disticha* is a grand plant; it is vigorous in growth, producing ample foliage, and strong conspicuous red and yellow blotched flowers. These are all plants of the easiest possible culture, thriving in almost any soil or situation.—GEO. WESTLAND.

Foxgloves amongst Rhododendrons.—Foxgloves are mentioned (p. 106) as being effective when growing amongst Rhododendrons at Kew. They are employed in the same manner and with very pleasing results at St. George's Hill, Byfleet. A sloping bank of dwarf Rhododendrons, amongst which both Foxgloves and Oriental Poppies grow with great luxuriance, formed this season one of the most admired and attractive features in these gardens. Rhododendrons, gorgeous though they may be when in flower, are apt when out of bloom to present a somewhat formal appearance. Anything, therefore, which may be utilised to break the rather monotonous aspect which they present during the summer months should be welcomed. Lilies are, as is well known, amongst the best of subjects for this purpose, but it does not lie in the power of every one to acquire a sufficient quantity of them to produce an immediate effect.

Foxgloves, on the contrary, owing to the facility with which they may be raised from seed, might be extensively planted wherever there is accommodation for them. The idea has frequently occurred to me that where Rhododendrons are planted in large masses, it would be better to restrict their development, and instead of allowing them to form a dense even surface of foliage, to so arrange as to leave semi-open spaces in which to naturalise some of the robust-growing species of flowering plants which naturally succeed well in such situations.—JOHN CORNHILL.

Large White Achilleas.—There are many of the ranker-growing kinds in the vast family of Composites which, though they are unsuitable for the ordinary flower border, are capital plants for shrubberies and the rougher parts of the garden. Amongst those best adapted for such purposes are the large-growing kinds of *Achillea*, some of which are represented in the annexed engraving. When planted in wide masses in shrubberies, or under the shade of trees, the effect of the large white flat heads of flowers is very striking, and it is enhanced by the partial darkness and green of the surrounding woods. They will thrive in any kind of soil, and produce seed freely in favourable seasons. The kinds best suited for the purpose are *A. magna*, *dentifera*, *tanacetifolia*, *Parnica*, and *impatiens*, all growing from 3 ft. to 5 ft. high, and having white flowers and finely-divided feather-like foliage.—W. G.

Wild Plants in Rock Gardens.—To show to your readers that beautiful objects may be enjoyed on rockeries without seeking for them amongst orthodox collections or rarities, I would mention the wild *Thyme*, which I should never have thought of planting, and, in fact, did not plant; but two years ago, securing a quantity of large stones from the Ingleton lills for rockery purposes, one of them had a plant of it in a small crevice; the stone was placed that side uppermost, and, without any more attention whatever, that stone is now covered with a fine patch of *Thyme* nearly 2 ft. through, looking as natural as it could have done on its native hill.—J. WOOD, *Woodville, Kirkstall.*

The Blue Daisy.—Having tried *Bellis cœrulescens* from seed in several kinds of soil and positions, I have come to the conclusion that it cannot be called blue. In comparatively dry places it has, however, both a pretty habit and tint of pale transparent mauve, making it a pleasing plant, if a disappointing one.—J. WOOD, *Woodville, Kirkstall.*

FERN COLLECTING IN SCILLY.

It is well known to those who have visited these beautiful islands, that their principal botanical features are *Mesembryanthemums* or *Ice plants*, which grow here with a luxuriance nowhere to be met with in Britain; but it is perhaps not so well known that good collections of Ferns may be made by those who are enthusiastic enough to seek them among the rocks and caverns on the seashore, and in the crannies and crevices of the numerous old walls with which the islands are intersected. Probably nowhere else in Europe can finer plants of the beautiful dark green *Asplenium marinum* be obtained than in the fissures of the rocks at Deep Point, a headland of St. Mary's; but most of these grand specimens grow in altogether inaccessible places, and are far beyond the reach of the most daring climber. I was, however, able to obtain and bring home with me many fine plants of this species. I have placed them in a greenhouse where they are growing well, and have already thrown out numerous young fronds. It is almost impossible to cultivate this species in the open air at any distance from the sea, but in a stove with a temperature of about 80°, and a moist atmosphere, it thrives admirably, and produces a constant succession of seedlings.

Although the *Asplenium marinum*, or *Sea Spleenwort*, is the most beautiful of the Scilly Ferns, there are many other comparatively rare varieties that may also be obtained. I found among others *Asplenium Adiantum-nigrum*, somewhat rare, and having very small fronds, *Asplenium Trichomanes* (also rare), *A. Filix-femina*, *Lastrea Filix-mas*, *L. dilatata*, and *Polypodium vulgare*. *Osmunda regalis* is also to be found on a piece of marshy ground near Old Town, St. Mary's, but I did not look for it, as my botanical collection had already filled two large hampers.

During my sojourn on the islands I obtained cuttings of many varieties of *Mesembryanthemums* which I found growing in a wild state, and covering the numerous stone walls. The finest specimens of these plants are to be seen in the old graveyard at St. Mary's. My cuttings, I am happy to say, have all struck, and are growing vigorously in a cool greenhouse. The mildness of the climate at Scilly may be judged from the fact that many kinds of plants which with us require shelter and heat during the winter months, there grow luxuriantly in the open air all the year round. I saw a *Pelargonium* which covered the entire front of a small cottage, and which had

developed a stem—or I should say trunk—no less than 6 in. in circumference. A peculiarity of the islands is that they are almost destitute of timber, the salt-laden winds proving very destructive to all foliage in exposed situations. The late Mr. Augustus Smith tried the experiment of importing from New Zealand to his residence at Tresco Abbey several plants, such as Aloes, Yuccas, Dracenas, Tree Ferns, Castor-oil Plants, and many others, and has been remarkably successful in their cultivation. These grow at Tresco to an enormous size, and, apart from the natural beauty of the place, the gardens of Tresco Abbey are well worth a visit.

The Cottage, South Norwood Park.

ANNIE TYRRELL.

SEED FARMING IN ESSEX.

ONE of the most beautiful of floral displays to be seen in the open air in this country is a field of garden annuals when in full flower. The small patches usually seen in gardens fail to convey an adequate idea of their gorgeousness as seen growing in large masses. Notwithstanding the exceptionally unfavourable season, the majority of the annuals on Messrs. Carter's seed farms are looking remarkably well, and every precaution is taken to ensure the purity of each particular stock by frequent recourse to weeding out any that do not conform to their descriptions. Godetias occupy large breadths in various parts of the grounds; *G. Whitneyi*, though beautiful, is quite surpassed by its variety *flammea*, which is of a rich velvety-crimson hue; *Lady Albermarle* has flowers of a shade lighter than the preceding, but it is quite as desirable. Several acres are entirely devoted to Sweet Peas, to which special attention has been paid at this place with regard to raising new and desirable varieties. Amongst the most conspicuous kinds are *Invincible*, in black, scarlet, and striped colours; also *Painted Lady* and *Butterfly*, with its pretty white and blue-edged blossoms. A large breadth of the handsome *Bartonia aurea*, a Chilean annual of the *Loasa* family, is this year a complete failure, owing to the continued wet and sunless weather that was experienced early in the summer. Various kinds

Large White Achilleas spread into wide masses under shade of trees in shrubbery.

of *Candytufts*, too, have suffered from the same cause. Though these are now almost over, there is still enough left of the new *carmine* variety to enable us to say that it is a fine addition to the genus in point of size and colour, and admirably adapted for growing in pots. In the dwarf or *Tom Thumb* type of *Tropeolum*, one of the specialities here, many new varieties are constantly being raised and distributed. About two acres are devoted to these alone, and the effect which they produce when in full beauty is gorgeous in the extreme. The brilliant hues of such kinds as *Fireball*, and also the dwarf little *King of Tom Thumbs*, which grows but from 6 in. to 9 in. high, are toned down, as it were, by the more subdued tints of *Pearl*, *The Bride*, *Spotted King*, &c., have yellow flowers of various shades; one of the darkest forms is *King Theodore*, which has flowers of a blackish-maroon colour.

There are few prettier plants of a bold aspect than the many kinds of *Larkspurs*, especially the stock-flowered strains with *rosette-like* blossoms in all shades of colour, from pure white to deep purple and red. Of these there is a great quantity grown, and being arranged so that the colours contrast agreeably, they have a most striking effect. *Eschscholtzias* are in great demand, and comprise several varieties, including the double-flowered kinds. Besides the ordinary *E. californica* and *E. crocea*, there are the beautiful *E. Mandarin* (figured in THE GARDEN, pl. CIV.), *E. rosea*, and a pure white form. The clear red tints on the outside of the petals in *E. Mandarin* have a pretty appearance in the evening when the flowers begin to close. A new variety has also been raised here in which both the inside and outside of the petals are red in colour. *French Marigolds* receive particular attention, and one strain especially is as near perfection as need be, if a sturdy dwarf habit, a free-flowering propensity, and symmetrical and beautiful flowers are held

as a criterion. There is considerable variation in the shades of colour in this strain, and especially as regards the lacing of the petals, though all are first rate, and few better annuals can be grown. The *Clarkias* constitute another highly desirable set of annuals, and our attention was directed to several new forms amongst them raised lately. One of the most beautiful is a new variety of *C. integrifolia*, the petals of which are pure white with a star-like centre of a rich violet-purple. The older varieties, however, still hold their own against new comers. *C. limbata* and the various other kinds of the entire-petalled type are very gay, not omitting the little *Tom Thumb* variety, which is a capital sort for growing in pots. The *Indian Pinks* are represented largely here, and comprise some of the finest strains which we have seen both as regards variety of size and colours. The two varieties—*Crimson Belle*, with rich crimson blossoms, and *Eastern Queen*, with flowers of a rosy-lilac colour, deserve special mention. One of the most effective plots was devoted to the summer-flowering *Chrysanthemums* (*C. tricolor*), of which there are many varieties. Though the double-flowered sorts are very pretty, they do not surpass the original kinds. The best of the former are *Dunnett's Snow White* and a golden-flowered kind. The pretty little *Calabrian Soapwort* (*Saponaria calabrica*) is largely grown here, and comprises several varieties varying in colour from pure white to a deep rose. A host of other annuals too numerous to mention are extensively represented, many of which, such as *Nemophilas* and *Silene pendula*, were out of flower, whilst others, such as *Salpiglossis*, *Asters*, &c., are yet in tolerably good condition.

Amongst perennial plants a plot of *Carter's Auricula-eyed Sweet William* is particularly noteworthy, as it is the finest strain with which we have yet met. The plants are comparatively dwarf and very robust, and produce large heads of bloom, each of which measures 1 in. across, and is perfectly round, with smooth edges, while the colours are as well defined as those of a good *Auricula*. The pretty *Eccrenocarpus scaber* forms an attractive ornament when grown in the open ground and allowed to climb amongst tree branches, as here practised. In this way it flowers abundantly, and is very useful for cutting purposes. A plot is devoted to testing seedlings of novel

ties, great numbers of which are raised annually. Here may be seen the latest additions to the already bulky list of annuals and other popular plants.

Amongst the choicer sorts of vegetables Peas are the most interesting, and to these several hundred acres are devoted. Amongst new sorts, the best, we think, is one called *Stratagem*, which grows from 1½ ft. to 2 ft. high, and is extremely productive. It is a wrinkled Marrow with unusually large and well-filled pods. For market purposes it will stand unequalled on account of its dwarf habit and productiveness. Another called *Strength* is a handsome Pea, also dwarf in growth, and equally productive. Such well-known sorts as *Little Wonder*, *Challenger*, and many other kinds need no comment, except that here in their birthplace they grow very vigorously, and are now heavily laden with pods. The two varieties, *Culverwell's Telegraph* and *Carter's Telephone*, in reference to which there has been some discussion of late, may here be seen growing side by side, and it needs no expert to distinguish their peculiarities. They are both first-rate Peas, though, in accordance with the decision of the Fruit Committee at the last meeting at South Kensington, the preference must be given to *Telephone*. With regard to other vegetables, equal attention is paid to keeping the stock of each particular strain true by frequent recourse to what is termed "rogueing" or removing spurious kinds—no easy matter where vegetables grown for seed cover so large an amount of ground as they do here.

W. G.

Ivy-clad Walls.—Visitors to Kew Gardens may have remarked near to the main entrance an Ivy-covered wall. The happy and rather novel idea has occurred to the owner of draping the outside portion of this boundary wall. Would that this example

could be more generally followed. Naked brickwork is always uninteresting, and more or less unsightly; could its bare surface be clad with verdure, the general appearance of many buildings in gardens would be much improved. What has been done for the wall already mentioned might be effected elsewhere, and it would probably be found that other plants besides Ivy (although it must be confessed that it would be difficult to find so suitable a subject) might be utilised for the purpose. In some places circumstances might offer insuperable difficulties to planting on the outside, but there are certainly miles of wall which might at a slight expense have their bare, unsightly surface clothed with verdure.—J. CORNHILL.

The Van Houtte Memorial.—The interesting ceremony of unveiling the Van Houtte memorial took place at Ghent last Sunday in presence of a large number of his admirers. At three o'clock a procession, numbering several thousands, and composed of delegates from all the Belgian and many foreign horticultural societies, as well as the *élite* of Ghent, started from the station for Gendbrugge, where the statue is situated, close to M. Van Houtte's world-renowned nursery. The procession was accompanied by several bands of music, and at short intervals were magnificent wreaths sent by various nurserymen. Many of these were very large, being as much as 7 ft. long and 4 ft. wide—one, contributed by the *employés* of the late M. Van Houtte, and composed of about 800 blooms of the lovely Rose Louis Van Houtte, edged with leaves of *Rosa rugosa*, being especially striking. The statue was unveiled by the Burgomaster of Ghent, and speeches were delivered by the Governor of Hainault, Professor Morren, and other eminent men. The monument, which is the work of the rising young Belgian sculptor De Vigne, represents Flora placing a wreath on the head of M. Van Houtte, and is spoken of as a fine work of art. The proceedings, both at the ceremony and at the banquet held in the evening, were characterised by the greatest enthusiasm.

THE KITCHEN GARDEN.

ASPARAGUS CULTURE.

By M. GODEFROY-LEBŒUF.

M. GODEFROY-LEBŒUF, a well-known horticulturist of Argenteuil, has published a book on Asparagus, Strawberries, Figs, and small fruits, from which we translate the main portion of the article on Asparagus, that being likely to interest our readers at a time when special attention is being paid to the culture of this vegetable.

Varieties of Asparagus.—Originally there was but one form of edible Asparagus, the wild Asparagus (*Asparagus officinalis*), from which have sprung the common garden Asparagus and the Giant Asparagus. The former gave rise to the Early Pink Asparagus grown in Holland, at Uhm, and at Argenteuil, and the Late Pink Asparagus grown at the same places. Culture and selection have so great an influence on vegetables that they modify not only their constitution, but their mode of growth and their flavour. It is by dint of constant observation, combined with great care and patience, that the Asparagus growers at Argenteuil have succeeded in improving this vegetable by creating, as it were, two varieties, the Early and the Late, and that they have rendered those varieties permanent, so that they may always be depended on as being superior to their common parent both in size and quality. Asparagus is grown throughout the whole of France with almost equal care. How is it, then, that there are only certain privileged localities which produce it in such perfection in every way that even after twenty years' growth the same plants yield abundant crops? This apparent anomaly simply arises from certain growers having adopted an intelligent and rational method of cultivation. By this means the Argenteuil Asparagus has reached such a state of perfection that it is impossible to mistake it for the old-fashioned varieties. Compared with them it gives crops of triple weight and size, while the Early variety comes to perfection ten days earlier than any other known kind. The appreciation bestowed on this variety everywhere is consequently fully accounted for.

EARLY AND LATE ARGENTEUIL AND DUTCH ASPARAGUS.

Late Asparagus.—The Late Asparagus as grown at Argenteuil is often flat in form; the eyes are prominent and arranged in a spiral, and the point is short and stumpy. When well grown the heads are from $3\frac{1}{4}$ in. to $7\frac{1}{2}$ in. in circumference at a distance of $8\frac{3}{4}$ in. from the tip. Fig. 1 shows one of these heads drawn from nature. There were others grown at the same time which were much larger, but this one was chosen on account of its representing the purest type of this variety. The entire stem of the Late Asparagus when full grown measures from 5 ft. 10 in. to 7 ft. 8 in. in height. This variety is very vigorous, will thrive in almost any kind of soil, and lasts for many years. The crown of the root rises but slowly out of the ground; the Late variety therefore is better adapted for a shallow soil than the Early variety. It produces less than its congener during the first years of its growth; but, on the other hand, it lasts much longer. We have seen Asparagus beds twenty-seven years old which still yielded abundant crops, the heads measuring from $2\frac{1}{2}$ in. to $3\frac{1}{4}$ in. in circumference.

Early Asparagus.—The Early Argenteuil Asparagus (fig. 2) is generally round, but sometimes slightly flattened.

Fig. 1.—Late Asparagus.

Fig. 2.—Early Asparagus.

The eyes are not so prominent as in the Late variety, and they form less regular spirals. The point is conical, often swollen in the middle, and longer. The heads measure from $2\frac{3}{4}$ in. to $5\frac{1}{2}$ in. in circumference at $8\frac{3}{4}$ in. from the tip. Fig. 2 shows a head of Early Asparagus of the average size drawn from nature by M. Godefroy-Lebœuf. There were many heads grown at the same time which were much larger, but a medium-sized head was chosen as being a type of the variety which is most in favour in the Paris market. The Early Asparagus attains a much greater development than the Late, often reaching to the height of 10 ft. It is very vigorous, and is not particular as to the richness of the soil; nevertheless it requires a depth of at least 10 in., for the crown of the root rises every year about $\frac{1}{2}$ in. It begins to yield at the end of the third year, and from six years old it gives

good crops for from fourteen to fifteen years. After this time the heads are somewhat smaller, but the crop is abundant. When well cultivated it will continue yielding for from eighteen to twenty years.

Dutch Asparagus.—Dutch Asparagus (fig. 3) is nearly always round. The eyes are arranged spirally, and are narrow and prominent. The tip is sometimes conical, at others elongated, and at times swollen in the middle. The heads are from $1\frac{1}{4}$ in. to $3\frac{1}{2}$ in. in circumference, measured at $8\frac{3}{4}$ in. from the tip. Fig. 3 shows one of the finest heads of this variety, drawn from nature by M. Godefroy-Lebœuf. The general height of this Asparagus is about 5 ft. It is neither so handsome, so well-flavoured, nor so tender as the two Argenteuil varieties. It also requires a much richer and deeper soil; its cultivation in France, therefore, has been given up by the best growers. Among other defects which are laid to its account are the following: it very soon grows hard, it opens its point very rapidly, and turns green in twenty-four hours. This variety fetches but a low price in the Paris markets, where it is sold at 1 franc a bundle, while the Argenteuil variety of the same size fetches from three to four times that price. It is not a good plant for cultivating on a large scale, while for amateur growth it is unsuitable on account of its small yield and its bitter flavour. It should only, therefore, as a rule, be grown where other sorts cannot be obtained. It has been estimated that it yields only a quarter of the crop furnished by the Argenteuil sort, all other things being equal. It also needs greater care and a larger quantity of manure.

The Soil.—Asparagus may be grown, and will thrive, in almost every kind of soil; heavy and damp soils, however, must be lightened before they will yield abundant crops. The best soil for growing Asparagus is a light one, either calcareous, siliceous, or granitic. If the soil is hard and heavy, it must be made lighter during the first few years by spreading over the stools a certain quantity of sand, lime-kiln, or other ashes, coal-dust, and similar inert materials, until it has lost its property of hardening and cracking during the dry season.

Preparation of the Ground.—Generally speaking, a great deal of very useless trouble is taken in the preparation of a piece of ground intended for an Asparagus bed. Some growers dig out the whole of the soil to the depth of 3 ft. or 4 ft., filling up the void with masses of manure, which, instead of favouring the growth of the crop, are not only lost but are absolutely injurious. When the spot on which the Asparagus bed is to be formed has been decided on, it is only necessary to turn up the soil to the depth of from 10 in. to 12 in., either before or after the winter sets in. Large and small stones must be carefully removed, so as to render the soil easier to work. Asparagus requires a firm soil to root in; we must be careful, therefore, not to dig down below a greater depth than 12 in., for if the roots bury themselves at too great a depth they will feel the effects of the atmosphere in a very small degree. Their growth will be consequently retarded, the crop will be smaller, the heads thinner, and the plants shorter-lived. The soil ought to be allowed to remain fallow after digging, that is to say, nothing but the rake should be passed over it to make all smooth—thus enabling the frost to have a greater action on it than other-

wise. Whatever may be the quality of the soil in other ways, it is of the greatest importance that the ground should be cleared of stones great and small, as they not only prevent the heads from appearing above the surface, but, by lying on the tops of them, cause them to bend and become deformed. The ground should also be kept clear of weeds.

Manuring before Planting.—Except in the case of poor soil, we need not give any manure before planting. If the soil is exhausted, we should dig in—either in September, October, or November, but not later—a quantity of well-rotted manure, so that by the end of the winter, when we are about to plant, we may find the whole of it resolved into soil. As a general rule, we must never manure at the time of planting, for manure attracts insects, and insects attract moles and mice, all of which are very injurious to the young plants.

Choosing the Plants.—If we sow Couch Grass we shall certainly not reap Wheat; and if we plant a sickly-looking, weak tree we shall never produce one that is healthy and vigorous. If, therefore, we plant puny Asparagus plants we shall only obtain a wretched crop. We have often heard it said that it matters little whether the plant is strong or weak, and that as long as we cultivate properly and give plenty of manure, we must necessarily obtain firm and well flavoured Asparagus. There is only one species of edible Asparagus, but there are almost as many sub-varieties as there are growers, for when the plant is grown from seed it infallibly varies when the seed-plants are not specially grown for the purpose. It is necessary, therefore, to choose our seed from those plants which produce the finest growths. Between the wild Asparagus and the varieties which are cultivated nowadays the difference is very great. Notwithstanding this, they are all produced from the same type. Amongst these sub-varieties there are all kinds of shades, but between the wild Asparagus and that grown in Holland and at Argenteuil there is a wonderful difference. Take a walk through the Asparagus beds of Argenteuil, St. Denis, Gennevilliers, Colombes, and Sannois, and when the time for cutting arrives, notice the shape and quality of the heads and taste their flavour, and you will soon become convinced that the different sorts cannot be mistaken for each other, neither as to earliness, quality, form, vigour, or general appearance. It is not sufficient to find out the localities which are celebrated for the best growths of Asparagus, but we must also find out whether they are grown by A or by B, and even then we may be at a loss, for in one plot B may grow a crop which leaves nothing to be desired, while the crop in the very next plot may be worthless. In using the terms variety and sub-variety we do not intend them to be understood in the strict botanical sense; they must therefore be looked upon as cultural expressions, that is to say, that these varieties are capable of returning to their original type if they are neglected or badly cultivated. Nothing, therefore, is so difficult as to procure varieties not merely of good quality, but of exceptional quality. The choice of plants is therefore a matter of great importance in growing Asparagus; so important is it, in fact, that we should reject all stools offered at a cheap rate, and always pay a fair sum for them, as long as we are sure of obtaining a good variety. What possible good can there be in exercising economy in purchasing cheap stools which will only yield one-half or one-third of the crop obtainable from the best varieties for a few extra pence? In those localities which are most renowned for Asparagus—at Argenteuil, for instance—the growers attach the greatest importance to having good varieties, and they not only choose them from amongst their own plants, but from amongst those of their neighbours, so much so that a grower who has cultivated a number of seed-

Fig. 3.—Dutch Asparagus.

bearing plants with the greatest care suddenly finds himself deprived of them just as the time comes for gathering the seed. It has also happened that the stools were destroyed by those who stole the seed, so that the proper owner of them was no longer able to procure a supply at will. This trait in the character of Asparagus growers will show how much importance they attach to the choice of good varieties. Sharp growers, consequently, who have succeeded in producing rare sub-varieties, prevent them from becoming multiplied either by breaking off the fruit-bearing shoots or by destroying the seeds, so that they should only be recognised by those in the secret. If it is a difficult matter to obtain good seed plants in places where Asparagus growing is carried on on a large scale, it will be readily understood that it is almost impossible to find them in small gardens where the cultivation of Asparagus is almost unknown. How then are we to recognise a good plant? Nothing is easier to those who have seen it grow, or more difficult for those who have only seen it as a stool at the moment of planting. In making a choice, we must be certain of the seed in the first place, and ascertain that it comes from a good variety, after which we destroy all those young plants which show any signs of departing from the type which we are desirous of growing. This is an art which can only be practised with success by those who are thoroughly acquainted with rearing Asparagus. The wisest course to pursue, therefore, when about to commence an Asparagus bed is to go to some well-known firm with a reputation to lose, and to place full confidence in it for the choice of seeds and plants. Even when we have a thoroughly good plant in cultivation we must know how to gather the seed at the proper time and in the proper manner. In addition to this all of the seed even from the best plants is not equally good. The seed, for instance, which has been gathered from a stool which has flowered side by side with a bad or medium kind, and at the same time, is worth nothing, because it has been fertilised badly. Again, the seed should be perfectly ripe, and it must be kept properly after it has been gathered. The last heads generally yield nothing but doubtful seed, which seldom reproduces the proper type. The seeds which grow at the end of the shoots also, as well as those produced by the upper and lower extremities of the stem, have the same defect. Those seeds, too, which are not sufficiently ripe or which are too small are sure to produce bad plants. Seed should be only collected from those plants which have reached the age of from seven to ten years and which carry but few seed-vessels. The seed-bearing stems also yield bad seed. By the above we can easily see that the difference between the difficulty of procuring good seed and good plants is enormous; we therefore recommend the amateur and small grower to give up all ideas of raising Asparagus from seed.

The Age and Strength of the Plants.—Two-year-old stools are still planted by some, but for a long time past practical growers have given up planting stools of more than a year old. The plant from a two-year-old stool is always a bad one, no matter what may have been the amount of care which has been bestowed on it, for the reason that it produces too many heads, which consequently lack strength and sap. General weakness is the consequence, and the crops are all puny and of poor quality. Asparagus is a plant of vigorous growth, but no plant in proper health would stand transplanting the second year without suffering from it; it would, in fact, give an abortive growth, which would never produce good heads. A plant which has come off a healthy stock is sufficiently strong for planting at a year old, and all of an older growth should be neglected. Great attention, therefore, is necessary in our choice of plants, and, as we have said before, bad goods are always dear, more especially in the case

of Asparagus. The strength or size of the stools is of little consequence if the seed has been good, so that at the end of the second year there is but little difference between them.

Form of the Ground for Planting.—If you wish to plant a plot of Asparagus distinct from the rest of the kitchen garden, you must open several trenches at about 36 in. apart, 10 in. deep, and 10 in. wide, throwing up on each side the earth taken out, so as to form a mound, as shown in fig. 4 at RRR. The line which passes beneath the letters HHH shows the level of the earth, and the upper part of the earth taken out of the trenches. The letters MM (fig. 4) show the stools in their proper position before they have been covered with a layer of earth. It will be noticed that the sides of the trenches are almost perpendicular below ground, and that above ground they form an angle with the mound at the level of the soil. This angle disappears as soon as the stool is covered over with earth, and the base of the mound is at the bottom of the trench, the sides meeting in an angle at the top. Beware of digging up the bottom of the trench, or of hoeing or raking it as recommended by many authors. The soil should be left alone, for Asparagus likes to run over the surface and not to penetrate beneath it; besides, as already stated, the roots, if they penetrate too

Fig. 4—Asparagus trenches.

deeply, will not feel the beneficial effects of the sun during the spring. On the other hand, they may meet with a subsoil that is cold, damp, and dry, all of which conditions are unfavourable to the plant, independently of the fact that the manure which has been applied has great difficulty in reaching the roots, either nullifying its effects entirely or retarding them considerably. If the soil is very light, instead of digging trenches of 10 in. make them only 7 in. or 8 in. in depth. If the ground is very dry and we plant late, the trenches should not be more than 10 in. deep, and a hole of from 2 in. to 2½ in. should be dug out to receive the stool. Loose earth is then thrown in and the whole is filled up until it takes the form shown in the cut (fig. 4). If you do not wish to have an Asparagus plot distinct from your ordinary kitchen garden, open several trenches a yard wide at a distance of 3 or 4 yds. from each other and plant in two rows. By adopting this plan your Asparagus will have a considerable space over which to spread its roots, which will by this means run no danger of becoming entangled with those of the plants in the neighbouring trenches. They will thus become finer, more succulent, and will last longer. Most authors recommend the use of long trenches dug to the depth of at least a yard, and filled up with all kinds of manure and composts. Experience has shown for a long time past that no method could be much worse than the one just described. Besides being expensive, the yield of Asparagus is late, sparse, and weak; in fact, it is the primitive method of growing Asparagus.

Distance between the Plants.—When we plant in an open plot the stools should be at least 3 ft. 3 in. from each other, but if two rows of plants are grown side by side they should be 2 ft. 8 in. from each other. For our own beds we have adopted a uniform distance of 4 ft. between the lines,

the plants being 3 ft. 3 in. apart. By this means we have more room for the earth taken out of the trenches, and the mounds are more easily made and kept in order. This method, therefore, is the cheapest in the end. Whatever may be the distance, the weight of the crop is about the same if the plants be kept properly apart, but crowded Asparagus beds produce late and smaller crops of very inferior appearance and quality, besides which they are much more quickly exhausted. They require more manure, and their cultivation is much more difficult and costly. Such plantations are more liable to the attacks of insects, and become unfit for good plants, seeing that they degenerate towards the original stock much more quickly. We have, therefore, everything to lose and nothing to gain by not planting the stools at a sufficient distance apart.

(To be continued.)

GARDENING FOR THE WEEK.

Stove.

All winter-flowering stove plants have now approached the stage of their growth wherein it is necessary to pay them particular attention. Except they are got sufficiently forward before the season is too far advanced for them to attain full size and strength, it is useless to expect their bearing anything near the amount of flower of which they are capable. To accomplish this they will now have been in their blooming pots some time, so that their roots will have got fairly hold of the soil. With plants grown for this purpose, which in the case of many are either destroyed after flowering and their place taken by young stock grown from cuttings, or cut back, shaken out, and partially disrooted, it is desirable not to use larger pots than necessary to admit of the full development required; but to assist this manure water should now be freely given, as the flower they are ultimately capable of producing is much more dependent upon the strength they attain before autumn than upon assistance that can be given them immediately previous to their blooming. Stock of most things of this description is later than usual, requiring extra care to get it up to the desired condition. Give all the light possible by keeping the heads of the plants close to the glass; and by placing them far enough apart to prevent their becoming drawn.

Poinsettias, both such as were propagated from cuttings this spring and those grown on from the cut-back stools, require to be carefully watered, so as not to permit of the soil getting dry, or they are sure to lose their lower leaves, which much interferes with the appearance of the plants when in bloom. The treatment they require, with a view to the production of large or small examples, needs to be regulated according to the character of the house or position they are to occupy when in flower. Strong, tall shoots, such as when the plants are confined to a single stem, bear much the largest flowers, and are suitable for houses of considerable size, whereas in smaller structures smaller specimens will be found more useful. When the plants are large enough it is usual with some cultivators to turn them out-of-doors for a short time with a view to maturing the wood and inducing a disposition to form flowers rather than to continue making growth; the exposure in this way generally results in the loss of foliage, and on cold, late summers like the present they are better under glass, giving them abundance of air, with but little or no fire-heat, except when the weather is cold, which will equally effect the maturing process required.

Euphorbia jacquiniæflora.—So useful for cutting! If the plants are at all backward there is yet time to grow them on to a considerably larger size, as the bigger they get the more flower they will produce. They may be stopped once yet where it is desirable to give them a more bushy habit, and they can be kept on growing right through the autumn. This is a comparatively tender, spare-rooted subject, succeeding better with less pot-room than many plants, and one which is much benefited by manure water.

Plumbago rosea, **Sericographis Ghiesbreghtii**, and **Thyrasacanthus rutilans**.—The plants of these intended to bloom as early as they can be had in should now be fast approaching the size that is required, and ought as soon as this is attained to be subjected to a maturing process, such as advised for the Poinsettias. The ever-blooming *Scutellaria Mocciniana* may with advantage now have the flowers nipped out as they appear, which will have the effect of enabling the plants to attain more size, and so will permit of their bearing more bloom at the time when wanted. So free is this *Scutellaria* in flowering that there is

no necessity for any maturing process; simply keep the plants growing on slowly.

Bouvardias.—Where dependence for the coming winter's supply of these flowers has to any extent been placed on spring-struck cuttings, except where the cultivator has had at command sufficient heated pits or other structures wherein to grow them, the plants are in most cases so small and backward as to be in anything but a condition for producing the full amount of bloom. They likewise are amongst the freest of free flowerers, not needing the wood to be hardened before the blooms are set, in the way that many plants do. Pinch out any flowers that may be formed, and encourage growth by warmth, plenty of light, and sufficient moisture. Stout plants from stools that have been cut back, if wanted to bloom early, may, during the next month, receive more air, with a drier atmosphere, ceasing syringing them overhead previous to their being subjected to more heat, with a view to bringing them into flower.

Autumn and Winter Flowering Begonias.—The heat-requiring kinds of these intended for autumn and winter bloom must have plenty of light and air, with sufficient warmth to keep them moving, so as to enable them to make stout, well-developed growth, removing any flowers that may be formed, as it is impossible to concentrate too much strength in everything of this character which is intended to bloom in the winter, when the production of flowers is altogether dependent upon fire-heat and the strength stored up in the plants.

Gesneras of the zebrina section, so useful for winter and spring flowering, should now receive every encouragement to make stout, strong growth; they can scarcely have too much light, and only require slightly shading so as to keep their foliage from being injured. They look the best grown singly in 5-in. or 6-in. pots. One of the principal things in their cultivation is to keep them free from insects such as red spider, thrips, and above all mealy bug; wherever these are allowed to become established upon them the lustrous colour of the foliage gets so far injured as to destroy half their beauty, as when the leaves are perfect they add much to the bright panicles of flower. Weak liquid manure at this period, when the pots ought to be getting full of roots, will be of the greatest assistance to them.

Abutilons.—One of the most serviceable and continuous-blooming subjects, producing its flowers freely in winter, with a moderate amount of warmth, is the white-flowered *Abutilon Boule de Neige*. Amongst the numbers of new varieties that have made their appearance there does not seem to be any equal to this; colour and form both make it acceptable for cutting; it is alike suitable for bouquets, vases, or any arrangement of cut flowers, and likewise handsome on the plant. It propagates readily from cuttings, and is a very free grower. Where any deficiency of stock exists it is advisable to get in cuttings now, which will make useful plants for next year; and, though propagated at this time, they will not be able to bloom near so much as stronger examples during the winter and spring; yet they will produce some flowers, as it is one of those plants that, when sufficiently rooted to grow away freely, at once form bloom. Examples that were struck in the spring, and are at all deficient in pot-room, may yet have another shift. It is a good plan, where there is a bare portion of wall available in an intermediate house, to cover it with this plant turned out, if there happens to be a border where its roots can be accommodated, otherwise in a large pot or box; being a strong grower, it is no better for having too much root-room. Treated as here described, it will give a supply of its beautiful white flowers almost all the year round, and by a judicious use of the knife in cutting the strong shoots well back from time to time, the whole surface of the wall from top to bottom can be kept furnished with flowering wood. The small-growing *A. vexillarium* and *A. vexillarium igneum* are well deserving of cultivation. They are much weaker growers than the better known members of the family, producing smaller flowers in greater abundance, and are very much preferable to many of the more vigorous kinds. They are excellent subjects for forming standards of medium height. Cuttings put in now of the soft half-ripened shoots will make beautiful blooming examples next year if kept a little above greenhouse temperature during the winter. These plants, though generally classed as greenhouse subjects, I have found do very much better with intermediate warmth through the winter.

Aphelandras.—The useful autumn-flowering *A. cristata* will shortly be pushing up its bright orange-red flowers, and will be assisted by a continuous supply of weak manure water until they open. It lasts for a considerable time in bloom, and a succession may be secured by growing a portion cooler through the summer; to effect which it is a good plan to keep several strong established plants that are cut back closely each year after flowering, striking cuttings of some of the shoots in spring, which grow on to form a

succession. Where stock of this latter description exists, by keeping them for the next two months a little cooler, they will come in later in the autumn. The charming little *A. aurantiaca* Rozzi should be grown in quantity by all who have a stove; its intensely bright coloured flowers are produced in the late winter and early spring months upon plants only a few inches high. Thus managed, three or four together in 6-in. pots, it has an excellent effect when placed about on the front stages and similar positions in stoves or intermediate houses. Spring-struck plants of this should be encouraged by enough pot-room, warmth, and moisture during the next six weeks to gain strength, for although, as already said, it will bloom from the merest bits, stronger examples will produce proportionately larger flowers.

***Æchmea miniata* and *fulgens*.**—The rage for variegated-leaved plants has caused many to discard these in favour of the more effective foliaged kinds; but any one possessing a number of them grown in small pots will find them most useful from this through the autumn months, as if not kept too warm they will be at their best during this period; the flowers will last in good condition for two or three months. Where there are old specimens that have been grown in strong heat and have bloomed early, they may be increased now by dividing the crowns, which should be split off from the main stem and inserted in 6-in. pots in sandy peat or loam well drained, potting them just to their lower leaves; kept slightly moist and warm they will root directly, and will form growth from the base of the bottom leaves, which will flower next autumn. Though large specimens of these with from six to a dozen blooming crowns are very effective, they are not so generally serviceable as when confined to single crowns in small pots.

***Cyrtoceras reflexum*.**—This Hoya-like plant is an excellent late summer-flowerer. Where the treatment has been such as to induce it to bloom at this time, it will now be coming in and will bear placing in a conservatory where the temperature is not allowed to go too low in the nights and where it is not exposed to a current of cold air. But whilst here it, and anything of a like character, must be carefully guarded from getting over much water at the roots, or it will prematurely shed its flowers in a few days.

Allamandas.—The individual flowers are of great use for mixing with other things in filling shallow vases, or the base of the stands now usually employed. Plants of them if well treated will continue to bloom almost the whole year round; they are gross feeders, and to keep them on flowering the roots must be continuously supplied with stimulants, which may be given in a solid state by placing an inch or two of rotten manure on the surface of the pots, boxes, or borders in which they are grown, or by regular applications of manure water. The three handsomest flowered kinds are *A. nobilis*, *A. Chelsoni*, and *A. grandiflora*, the two former much the best for cutting as they have more substance, and their beautiful rich colour makes them more effective. Managed as above described with sufficient warmth they will afford a never-failing supply up to the end of the year.

Gloxinias and Achimenes.—The earliest-flowered will now want to go to rest. Beginners in the cultivation of stove plants are frequently led to attach little importance to the gradual maturation of such things as these when the flowering is over and the leaves begin to look shabby, allowing them to die off too quickly; it is through this cause more than any other that the roots are so often found decayed in spring, in place of being plump and ready to start into growth. When they show signs of wanting to go to rest, they should still be kept in a warm house, fully exposed to the sun and light, just giving as much water as will keep the leaves from flagging to any great extent. This treatment with plenty of air will induce rest. When the leaves and stems have thus gradually died down, the roots will be in good condition, and no difficulty will be experienced in preserving them through the winter if they are kept dry, and not allowed to get too cool.—T. BAINES.

Flower Garden.

Auriculas.—The seed pods of these will now be ripe even in late districts, and the seed should be sown immediately. Many experience a difficulty in raising seedlings, but that can only occur when the seeds are bad. I use soil consisting of leaf-mould, good maiden loam and sand, without any manure. I make the surface quite level, and then just cover the seeds with fine soil. In a fortnight plants will appear, but the largest proportion of seeds will lie dormant until next year. After sowing place some Moss over the surface, and if the Moss is kept moist the soil will not become too dry. If the soil be kept in a moderately moist condition, neither too much one way nor the other, there need be no fear of the results. Offsets that were put into very small pots at the time when the old plants were repotted in May will now be ready to be shifted into 3-in. pots, and if well cared for many of them will produce trusses

of flowers next blooming time. We have now finished the potting of old plants and put in offsets from them. Some sorts require the offsets removed before they injure the plants. In others offsets are always scarce because they seldom give any increase from side growths. It is a good plan to head over any plants that seem to be breaking out from the main stem. The top will strike roots under a bell glass, and side shoots will be thrown out very freely.

Carnations and Picotees.—In such a season as this it is not likely that there will be much seed saved from these, even in the south. A good grower from the north informed me that he had not been able to save seeds there for several years. It is necessary to artificially fertilise the blooms in order to obtain seeds at all, and in doing so it is advisable to choose well-marked flowers. Mr. Dodwell has been working on the scarlet Bizarre section, and has been successful in raising some very good and distinct flowers from crossing Admiral Curzon with Sir Joseph Paxton. Any of these two fine flowers crossed with Mars (Hexall) would give good results. The pink and purple Bizarres are a weak class, but by crossing Sarah Payne with James Taylor good flowers would be produced doubtless. Light and red-edged Picotees might also be tried. This is a very weak class. Violet Douglas, Thomas William, and Mrs. Bower are all good, and may be selected as parents. We have now begun to layer, and should have been at it sooner but for the pressure of other work and not disturbing the plants when in flower. We have generally finished by the first week in August. Last year we were later. This season they will certainly not be finished by the end of September. Before commencing to layer we strip off a few of the under leaves, and remove 1 in. or so of the surface-soil in the pots; this is replaced by some sandy soil. A notch is made in the stem of the layer, and it is then pegged firmly into the new soil. After the layers are put down, the plants must be placed out-of-doors in an open position.

Hollyhocks.—The disease has appeared in some gardens, and where this has happened the best way is to dig up the plants and burn them. It is nothing more than a parasitic fungus growing on the leaves, but it enters their tissue and takes such a determined hold that any dressing strong enough to kill the parasite will also destroy the leaves. No doubt the warm, rather close atmosphere of the last few days has encouraged the development of the disease.

Pansies.—Cuttings of these may be put in whenever it is convenient. The old plants will make a fine autumn display if the very old spent stems are cut out. All small, weak stems should also be pinched out and used for cuttings. Place a rich dressing of rotten manure and loam in equal portions evenly over the beds between the plants, then peg down the medium growths over the compost, and if the soil is rather dry give a good watering. The small, hair-like roots run into the dressing in a mass, causing the plants to make a corresponding growth above ground.

Polyanthuses.—We have planted out a very large bed of seedlings into their blooming quarters; some rich manure was dug into the soil, and a dressing of rich loam was also placed over the beds previous to planting. The plants were put out 9 in. apart; they were the produce of seeds sown in April, and will quite cover the ground and flower freely next spring. We are also lifting named varieties from the open ground, and potting them after breaking the crowns into as small portions as possible. The large crowns are potted in 5-in. and the small ones in 4-in. pots. The leaves were pretty well covered with green fly, but we dipped them in soapy water, which destroyed it.—J. DOUGLAS.

Indoor Fruit.

Vines.—It cannot be too often reiterated that all Grapes intended to keep well throughout the winter should be fully ripe before the close of next month. Lady Downes, Gros Colman, Alicante, Mrs. Pine, and Muscats require a full two months from the date of beginning to colour to become fully ripe, and owing to the season being so backward, more than the usual amount of forcing will be necessary to attain this end by the time named. Whenever there is sunshine the houses should be closed up by 2 p.m., and night ventilation should be put on at 7 p.m., accompanied by artificial heat in order to maintain a minimum temperature of 65°, or, if very late, 70°. If the borders are inside give them a thorough watering when the Grapes just begin to colour, and repeat the operation if necessary any time before the fruit is fully ripe. The rainfall has been excessive, and therefore in some soils and localities outside borders will need coverings to throw off the rain, but on light soils and naturally drained borders such coverings need not be resorted to till the Grapes approach maturity, when they are necessary. In order to colour Gros Colman well, we find it requisite to let the lateral growths extend as much as possible, and to tie aside the foliage to admit full sunlight to the bunches. Grapes that are ripe should be kept as cool as possible, but apply fire-heat in cold damp weather in order to keep the atmosphere buoyant, or, the condensed moisture settling

on the berries will cause them to decay. Early Vines may now be partially pruned, *i.e.* all the laterals may be cut off, and the longest side shoots shortened back, but the old foliage should be left intact and kept free from red spider by frequent syringings. If necessary the borders should now be renovated and surface rooting encouraged by the addition of fresh material. Outside borders like those of late houses may now require protection from further supplies of moisture.

Figs.—All kinds of cultivated fruits do best when surface-rooting is encouraged by frequent mulchings, or additions of fresh soil, but none more so than the Fig. I have noted that the shallower, comparatively speaking, the border is for Figs the more fruitful are the trees. Of course, the labour of watering and mulching is increased, but not in proportion to the results. All trees now swelling off heavy crops of fruit should be thus surfaced, mulched with one-third rotten manure and two-thirds loam, with a small proportion of lime scraps and charcoal added, the whole to be covered with a slight layer of stable litter. Water freely with guano or other manure water, and syringe the trees on fine days at shutting-up time till the fruit begins to ripen, when a drier atmosphere should prevail, combined with abundant supplies of air so long as draughts are avoided. Early houses will now be going to rest, and moisture, both at root and top, must be lessened, but anything like aridity of atmosphere or real dryness at the root must be guarded against. Any useless shoots not required for next year's fruiting may be at once removed, an operation which will give those that remain a better chance of ripening. Pot trees that have done fruiting may now be placed in a sunny position in the open air to consolidate their growth, but they will require to be occasionally examined to see that the roots do not protrude through the bottom of the pots; if they do they should be cut off, as such rooting tends to an undesirable late growth of the shoots.

Melons.—The last batch of plants should now be well established, and to be certain of satisfactory fruiting not less than 75° as a minimum bottom heat must be maintained, and top heat according to the weather. On bright, sunny days the temperature may run up to 85° or even 90°, provided the walls and floors are kept sprinkled; in other respects treat them as recommended for early crops. Plants that are swelling off heavy crops water thoroughly with tepid manure water. Generally too little water is given at this stage, and consequently the foliage perishes and the fruit is flavourless. It is a mistake to suppose that starvation, by withholding water, adds flavour to the fruit. Sun, and lacking this, fire-heat and air, are the flavour-producers.

Peaches and Nectarines.—From the earliest houses the lights may now be entirely removed. If the foliage be loose, a gentle brushing will bring a good deal of it down; having performed its functions it is best off, and the wood is better for full exposure. The lights may then be entirely removed, or, if this be impracticable, all the ventilation possible should be given. Any trees growing too luxuriantly should be lifted and replanted, and the borders top-dressed; as a matter of course, now is the best time to repair and paint the houses. Treat late houses that are in full fruit liberally, as regards water, and keep red spider in check by syringing up to the time that there are indications of ripening, when plenty of air and all the sunlight vouchsafed us should have free play on the fruit by the removal of surplus shoots and laterals, and the turning aside of large leaves.—W. W.

Kitchen Garden.

Potatoes of every kind hereabouts are attacked in so really virulent a manner by the disease that it will be useless to leave any in the ground; they should be forthwith dug up, and all that are in the least affected picked out, and the others, before being finally stored, should be spread out in a dry, airy shed for a few days, and again looked over, picking out any bad ones. The remainder should then be pitted, and kept as free as possible from atmospheric influences. The kinds that are least affected with us are Magnum Bonum, Red Emperor, International, and Myatt's Ashleaf. Spring-sown Onions, Shallots, and Garlic will all of them now be ready to harvest. The bulbs should be pulled up and left on the ground for a few days to dry, and then moved to the store-room to be finally cleaned and stored in bad weather. The ground which they have occupied will be in good heart for the main crop of Cabbages for early spring use. It need not be dug, but simply cleared free of weeds. Drills should be drawn 2 ft. apart, and the plants dibbled in 1 ft. apart, to admit of alternate plants being drawn out for use whilst young, and before they injure each other. The planting of all other kinds of winter Greens should now be finished, with the exception of Coleworts, which may be planted all the year round. A last sowing of Turnips, Winter Spinach, and Lettuces should now be made, for even though the supply may seem ample, it frequently happens that these last sowings stand the winter best,

and certainly in the case of Spinach there is not that liability to run to seed that the earlier sowings possess. Thin out crops of these that were previously sown, as soon as the seedlings can be handled; and keep the ground well stirred, particularly after dashing rains. The first-planted Celery will now require earthing up, but previously remove all suckers and small outside leaves, and tie up with bast in order to prevent the soil from getting into the centres of the plants. The general stock should not yet be earthed up, for once earthing is begun, growth is checked, so that, as a rule, it is best to allow the plants to get fully grown before earthing takes place, *i.e.*, if blanched Celery be not required at an early date, at least a month should be allowed for blanching. Where dry herbs are required for winter use, this is a good time for them; Thyme, Sage, Marjoram, Mint, Basil, and Balm should all be tied in small bunches, and if hung up in any dry room or shed they will maintain their natural colour. If dried in the full sun the leaves go black, and fall off when removed to their winter quarters. Even where dry herbs are not in request the plants will be all the better if shortened back and freed from flower and seed stems. Keep the stems of Tomato plants thin, and the foliage that overshadows the fruit picked off. Ridge Cucumbers also require to be well trained out, and surplus fruit constantly picked off, and if the present sunny weather continues, a fresh mulching of soil will be necessary in order to keep them in full fruit. Vegetable Marrows also require to have the fruit removed as soon as it becomes usable, in order to prevent impoverishment of the plants, and this, coupled with a bountiful supply of water, is about all the attention which they will require. Peas, Broad Beans, and all other crops should be cleared away as soon as they have become exhausted, both for the sake of neatness, and to prevent any unnecessary exhaustion of ground.—W. W.

Extracts from my Diary—August 25 to 30.

FLOWERS.—Putting in cuttings of Coleus for stock. Thinning out Chrysanthemums to give them more light and air. Re-arranging plant houses. Potting Pelargonium Stag's-horn and Lady Plymouth for winter blooming. Tying and training Clerodendron Balfouri to roof of stove. Staging Mignonette. Sowing fifty pots and six boxes for winter flowering.

FRUIT.—Tying and stopping Melons. Pulling up old Melons, and scrubbing house thoroughly with Gishurst Compound ready for winter Cucumbers. Planting border in Vinery with Muscat of Alexandria, Gros Colman, Trebbiano, and Abercainne Seedling. Fertilising Melons and cutting all ripe fruit. Gathering Green Gage and Washington Plums for preserving.

VEGETABLES.—Tying Tomatoes in Pine stove. Cutting Mint, Tarragon, Balm, Fennel, Basil, Marjoram, Sage, and Horehound; tying them in bunches and hanging them in herb room to dry for winter use. Sorting Potatoes, the large ones for eating, and the medium ones for seed. Top-dressing small Cucumbers for planting. Planting pit with Early Ashtop Potatoes. Preparing first Mushroom bed in house. Turning manure, and mixing with leaves and Grass to put in bed for winter Cucumbers. Sowing Mustard and Cress. Digging up the remainder of Regent Potatoes and Paterson's Victoria; also Magnum Bonum. Tying and stopping Tomatoes. Sowing three-light pit with Early London, Erfurt, and Walcheren Cauliflower to stand the winter and for planting early in spring. Digging up Compton's Surprise and Jersey Blue Potatoes.—R. G., *Burghley*.

The Potato Disease.—The following from Mr. Harrison, Saffron Walden, is a sample of the kind of reports which we receive from all parts of the country respecting Potatoes. "The Potato crop," he says, "up to the end of July was very good, but in a day or two the tips began to show signs of disease, and then on the night of the 2nd and on the morning of the 3rd a fearful storm of hail, rain, thunder, and lightning occurred. Since then the Potatoes have rotted wholesale, there being now only one-third sound. The Rector of Woodstock is nearly all gone; I have about 2 acres in a field of the Rector and Dahmhoy growing on the side of a hill on a light chalky soil, and these are the same as those in the garden, *viz.*, three parts rotten.

Celery Fly.—This made its appearance with me much earlier this season than previously. I was obliged to have all my plants picked over twice in July, and where a large quantity of plants is grown this is a troublesome operation. Quite recently I saw in a garden in the neighbourhood some plants that had been pricked out on a bed, and large enough to put into the trenches, with scarcely a green leaf on them; the pressure of work in other departments prevented their being picked over, and they looked not worth planting. Is there any better method of destroying it than hand-picking?—J. C. F.

PLATE CXCIV.

A GROUP OF NEW DAFFODILS.

Drawn by CONSTANCE PIERREPONT.

THE annexed plate represents a group of new Daffodils, a sample, so to speak, of the Longford Bridge and Wearsdale hybrids and varieties. These are the only two collections of new Daffodils, the result of crossing and seeding, supposed to have been produced within the last 300 years—with the exception of a casual form such as Sabini, which was evidently an accidental seedling, though Dean Herbert considered it to be a natural variety; this hybrid, however, has been raised both in Holland and in England within the last few years. It would have been highly interesting could we have given from the notes of the raisers a categorical account of how these new varieties were produced, but in the absence of data we must consult the plants themselves, and we propose to allow them to tell their own tale in the gradations and variations of their flowers. Dean Herbert held the theory that if Ajax and Poeticus be crossed the outcome would be *Incomparabilis*, and by gradual inter-crossing *Poeticus* pure and simple would be reproduced. On this theory the Wearsdale collection appears to have had its origin, starting with Ajax or the Trumpet *Narcissus*. *Emperor* and *Empress* are two giants. *Bicolor maximus*, of the Longford Bridge collection, though not so stately in growth as *Empress*, has the divisions of the perianth broader and altogether more substantial, and a more sturdy plant. *Volutus*, from Wearsdale, the yellow Daffodil on the right of the plate, though it cannot claim to rival its relation the *Emperor*, is a more refined flower, the trumpet being beautifully convoluted, of a soft clear yellow, overrun with a beautiful fretwork. *Bicolor J. B. M. Camm*, the bottom figure in the plate, is distinct, there being no previous variety with a sulphur-coloured trumpet. Here the blood of *Moschatus* has intermingled with that of *Bicolor*, and become fixed, for *Moschatus*, though the trumpet is sulphur-coloured when it opens, dies off white, or almost white. The variety *Shirley Hibberd* is another illustration of the Wearsdale Daffodils; the trumpet is unusually open, bevelling off to a comparatively narrow neck, presenting the appearance of a wide-mouthed goblet. When exhibited at South Kensington, this flower attracted an unusual amount of attention. The variety *Milneri*, the bottom figure on the left of the plate, may fairly be termed original, there being no variety known to exist which at all represents the colour. The trumpet and the divisions of the perianth are of a uniform clear sulphur, while the flower is smaller than the *Lent Lily*, and perfect in form. Now supposing that the Wearsdale collection originated in crosses made between Ajax and *Poeticus*, and the outcome was *Incomparabilis*, there are amongst the varieties some remarkable Daffodils, some attaining a height of upwards of 2 ft., others dwarfier, while the range in size of flower is from 3 in. to 5 in. in diameter. The corona or cup is also very varied: some are straight and round as a gun-barrel, others wrinkled or plaited; some are slightly marked with orange-scarlet, in others the orange-scarlet is strongly infused half-way down the corona; and in one of the varieties the corona is entirely scarlet, as will be seen represented in the centre figure of the plate. The divisions of the perianth in these varieties of *Incomparabilis* vary through bright yellow, clear sulphur, and creamy white, to snow white, forming in all cases a fine contrast to the coronæ, while in size the flowers are equally varied.

Still working upon Dean Herbert's theory a group of the Wearsdale Daffodils has the corona smaller than in *Incomparabilis* and similar variations in form and coloration. This group, for the convenience of nomenclature, has been named *Barri*. By a reference to plate 22 in Burbidge's book on the *Narcissus* a good idea of this section may be gleaned, as one or more of this group is here figured under the name of hybrid *Narcissi*.

Still on the basis of Dean Herbert's theory we come to a third cross which brings us to a group close upon *Poeticus*. Generally speaking, these flower a fortnight earlier than the early-flowering *Poeticus*. For identification this group has been called *Burbidgei*, and some of its members resemble *Poeticus* so much that but for their apparent hybrid character they might have been placed in the early-flowering *Poeticus* group. The coronæ of some are slightly marked, as in *Poeticus tripedalis*, while others have the scarlet suffused cup, as in *Poeticus poetarum*. Apparently a fourth cross has been made resulting in *Poeticus angustifolius* pure and simple, with another form of *Poeticus* lower in the scale than any existing variety. This brings us to the end of the Wearsdale crossings, so that any one desirous of following as it were the work of an indefatigable hybridiser, and estimating what intelligent crossing can accomplish in formation as well as coloration, can do so in a very limited space of ground at a trifling outlay, and without the intervention of glass.

The illustrations on the plate bring us to the Longford Bridge collection, to which we have already referred. In this we have varieties of extraordinary beauty and interest, although the collection shows none of the high-class grappling with the subject of crossing which the Wearsdale does. They have a more haphazard look than one would be led to expect from the result of forty years' labour. It is now many years since varieties of the Longford Bridge collection were first figured, but this is the first time in which any of the Wearsdale Daffodils have been illustrated in colours.

The plate includes three very distinct varieties of what, in the Longford Bridge catalogue, are designated "Shortened Bicolors;" but for the purpose of tabulation they have been classed as a distinct section under the name of *Nelsoni*, the central figure being *Nelsoni aurantius*; when the flower first opens the corona is scarlet. The left hand figure a little lower down is *Nelsoni*, while the small flower immediately under *Nelsoni aurantius* is *Nelsoni minor*. This section evidently has been originated between *Bicolor* and *Macleai*, but the scarlet on the corona can only be surmised as coming from *Poeticus poetarum*.

In the Longford Bridge collection are two very dissimilar groups under the name *Poeciliformis*, the supposition being that *Montanus*, sometimes called *Poeciliformis* and sometimes *Galanthiflorus* from its graceful, drooping, Snowdrop-like flower, was one of the parents. For purposes of nomenclature, these have been ranged under two sections, viz.—First, *Leedsi*, the flowers of which vary considerably; some of them run close upon *Incomparabilis*; others again have the drooping form of *Montanus*, but they differ so considerably from either of the varieties named that they are fairly entitled to rank as a distinct group. They have the corona in some cases clear canary, in others lemon, and in others silvery-white. Second, *Humei*; of this the plate represents two flowers—the one on the extreme right, the other on the left of *Nelsoni aurantius*—the trumpet and perianth being delicate transparent silvery-white. In this section there are two or three varieties, of which the one named is the most refined. The one which has been named *Humei paradoxus* is the most uncouth of the Daffodil family. *Ajax Hudibras* is also squat, square, and disproportioned. The left-hand top figure in the plate is *Pseudo-Narcissus Exquisite*, a remarkable variety on account of its sulphur trumpet and paler sulphur divisions of the perianth.

PETER BARR.

SOME WET WEATHER SHRUBS AND PLANTS.

Two of the most conspicuous shrubs this cold and drizzly season have been the Golden Yew and the Golden Elder (*Sambucus aurea*). The first has possessed a vividness of hue unusual to it, unless it be that it looks brighter under a dull sky and against the more verdant colour of the lawn; and the second has been nearly as bright as the Golden Feather *Pyrethrum*. I saw a long line of it lately against a mass of evergreens, and could not help thinking that, as a yellow-foliaged shrub throughout the summer, we have nothing to compare with it for general use, as it thrives in the most unfavourable exposures. The *Aucuba japonica* cannot compare to it for colour at this season, but looks positively dull beside the Elder. What a pity the variegated *Acer* is not such a vigorous grower! Down in the south of England it thrives well, and, when planted in masses, it is a really grand thing; but in the north it almost refuses to grow, except in sheltered situations. In a high and cold locality it has no chance. In a collection of herbaceous plants I saw a few days ago, one of the most conspicuous objects was the old *Betonica grandiflora*, which was one mass of purple flower, and had been so, I was told, for six weeks or two months. The plant grows about 2 ft. high, and for lines or massing in parks against shrubs, or for herbaceous borders, it is one of the best. The bed referred to had not been disturbed for years, and yet was making most vigorous growth. Next to it was the old but pretty bright blue *Veronica corymbosa*, doing equally well and flowering in great profusion, and producing a pleasant and striking effect; I have seen no bedding plants in such flower hereabouts this season. *Lychnis flos-cuculi flore-pleno* was also bright and pleasant, producing a very noticeable effect, at a distance particularly. The Sweet Williams hold their heads up manfully, and flower well, and the annual Candytufts, the *Spiræas*, and the old yellow Marigold help also to keep up the display, and seem to stand the dashing showers better than most other subjects. As an ornamental foliage plant, the old Gardener's Garter stands this season in the front rank, having grown unusually tall and fine. The Pampas Grass is almost a failure, and its substitute in colder localities, *Arundo conspicua*, is not much better, having begun to grow much later than usual.

In the flower garden Geraniums have only begun to grow, and other things are proportionately behind. *Coleus*, *Alternantheras*, and such like, simply grow less from the day they are put out, till they disappear altogether.

THE FRUIT CROPS.

METROPOLITAN AND SOUTH-EASTERN DIVISION.

Gunnerysbury, Acton.—Bush fruits are an average crop, and Strawberries abundant but flavourless. Of Apples, the only varieties bearing full crops are Manks Codlin, King of the Pippins, and Cockle Pippin; the fruit is small and scabbed, and the trees are suffering from blight and mildew. Pears are a very light crop, with the exception of Hesse, Louise Bonne, and Calabasse. These three varieties are plentiful, but the fruit appears to be hide-bound, and makes no progress, and it is also deficient in healthy pips, which shows imperfect setting. It will require a very fine autumn to make the Pear crop of much value. Cherries are a failure, and Plums the same, with the exception of Denyer's Victoria in a very sheltered position. Peaches and Nectarines where protected are moderate crops. Nuts and Walnuts are abundant.—J. ROBERTS.

Syon House, Brentford.—The fruit crops in this neighbourhood generally are not satisfactory. Most of them are much under the average, and nearly all are indifferent as regards quality. Apples, Pears, and Plums will be very scarce. The two former looked very promising at one time, but many of the fruits dropped off when about the size of Cobnuts. The Codlin varieties of Apples have stood best. Apricots and Peaches are a poor crop. The branches of the Apricot trees have died off more than usual this year—a strange circumstance, as the Apricot branch disease is usually attributed to drought. Strawberries and Raspberries have been very abundant, but in neither of them is there much flavour. Currants and Gooseberries in a few places are plentiful, but in others they are very scarce. Fruits of nearly every kind are late in ripening this year with the exception of Gooseberries. Tomatoes are very late, and it is doubtful whether any out-of-doors will ripen.—J. WOODBRIDGE.

Bedfont, near Hounslow.—This district ranks high as regards the extent of ground devoted to the growth of market fruits, and every year that extent is being increased, as although for several seasons past the returns have been comparatively small, yet all hope for a better future, and plant accordingly. The most trustworthy information obtained from growers shows that Apples are a very poor crop indeed, the produce resulting from a magnificent bloom being about one-tenth of an average crop, a few good crops here and there being far more than balanced by the comparative general lack of fruit. The best pickings so far are obtained from Early Juliens, and there are a few here and there on the Wellingtons and Kings. The usually well-cropped Manks Codlins are singularly scarce. Even of the fruit that originally set, more than one-half has fallen. Of Pears the returns are a little better. On the well-known Hesse, or as it is popularly termed "Hazel," there are fair sprinklings, but the fruits are so hard and woody through lack of warmth that they might almost be mistaken for Nutmegs. Beurré d'Amanlis is furnished with just a sprinkling, and Beurré de Capiamont is a trifle better. Marie Louise, Jargonelle, Winter Nelis, and Beurré Clairgeau are furnished with the merest sprinkling, whilst much of the young wood has greatly suffered, and on many trees a good deal is dead. Plums are very thin indeed; now and then may be found a sprinkling of Victorias and Prince of Wales, but quite one-half of the fruit fell at stoning time, and the remainder is swelling slowly. Cherries have been a wretched crop generally; indeed a complete failure, with the exception of a comparatively moderate crop found on standard Morellos. It is therefore remarkable that so few Morellos are planted. All Bigarreans and May Dukes have not paid for gathering. Gooseberries, one of the most useful and profitable of market fruits, rarely miss producing a crop; this year has, however, been at least one-third below an average, but the berries have been finer than usual. One kind that is supplanting all others is the Lancashire Lad, a sure cropper. Dobson's Seedling and Crown Bob stand next in favour. The Gooseberry is, however, most profitable for market in a green state, and therefore usually not more than one-fourth of the crop is left to ripen. Red Currants have been fairly good, as have also been Black Currants, but the bushes of the latter became considerably blighted as the fruit ripened, and thus affected its quality. Strawberries have been very abundant and cheap. Raspberries have been perhaps the very best crop of the season, but they have been unusually subject to mould if gathered in bulk. The kinds most grown are Filbasket and Red Antwerp. Apricots especially have fallen much during the stoning process. Wall fruits present no feature of interest in market culture, but generally where grown they are very thin. Small nuts are little grown in this locality, but Walnuts are largely grown, and promised early to be a large crop; now the produce is very thin, indeed a mere sprinkle furnishing few or none for picking. Altogether, following upon three poor fruit seasons, the present one will terribly try the market growers, for they have little to sell, and yet have heavy

rent, rates, and wages to pay. The thinness of Apples, Pears, and Plums is mostly attributed to the excessively heavy rains that fell in the spring, and the very low temperature at setting time. Gooseberries and Currants suffered most from frost, as did also Cherries. In large market orchards no special attempt to provide shelter is made beyond such as the overhanging standard trees or here and there a high hedge may give to the bush fruits, and these where most sheltered are yielding the best crops. Briefly summed up, the results are—Apples very few indeed; Pears rather more, but likely to be of little eating value; Plums a scanty crop; Cherries even more so; bush fruits and Raspberries fairly abundant; and Strawberries very plentiful. It is, however, the standard tree crops to which the grower has to look chiefly for his profits.—ALEX. DEAN.

Southgate.—Peaches and Nectarines on open walls generally are thin, even where protected whilst in bloom. Apricots are somewhat better. Of Plums we have very few. Cherries are under the average. Apples are a very thin crop; only such hardy kinds as Keswick Codlin, Lord Suffield, Northern Greening, King of the Pippins, Cox's Orange Pippin, and Cellini have any fruit upon them worth mentioning. Pears are better, but partial, and very late and small. Strawberries have been a very heavy crop, but deficient in flavour. Gooseberries moderate. Raspberries and Currants plentiful. Nuts show more than was perceptible a short time since; in some places they are heavy crops, in others thin. So far as the failing of the Apple crop is concerned it is just what I have invariably noticed to occur in seasons when the blooming was long retarded beyond its usual period, even when there was an absence of frost during the time when it opened, and this in localities widely apart, with soil and climate considerably different from each other. In this district and almost everywhere else there was a profusion of bloom, full-sized, and the organs respectively in many places where I examined them quite perfect; but as I have always before observed when the flowers have opened very late, they did not remain more than half their usual time, dropping almost by the time they were fully expanded, and under such conditions I have never yet seen a crop of this, the most important of all our fruits.—T. BAINES.

Royal Gardens, Frogmore.—Fruit crops both here and in this neighbourhood are generally thin and of inferior quality, owing to continued rain and the absence of sunshine. Apricots are a thin crop; those here which were protected with canvas blinds—growing mostly in a strong deep loam—set an abundant crop, but during the whole season the fruit continued to drop up to the present time. Plums are an average crop and promise to be of fair quality. Damsons very thin. Cherries on walls are an average crop, but quite a failure on standards; although they set freely, all dropped in stoning. Morello Cherries are a fair crop and of good quality, though not protected in any way. Peaches and Nectarines are under average; the trees suffered much from blight and made but little growth in the early part of the season; these were covered every night with canvas blinds, and a portion of them were under a glass coping. In some gardens in this neighbourhood the trees have suffered greatly, and many are quite dead. Apples are everywhere almost a failure, and the trees present a miserable appearance, many of them being almost leafless. The only kinds that are bearing any fruit are Rosemary Russet, Lord Suffield, Frogmore Prolific, Small's Admirable, King of the Pippins, and Flower of Herts. These are growing on various soils, but the result is much the same on all of them. Pears on mostly all varieties are a good crop, and the fruit promises to be of very good quality. Of small fruits we have had a good crop; Red Currants, Gooseberries, and Raspberries are abundant, but Black Currants are everywhere thin and inferior in quality; the trees, which were much blighted, are now losing their leaves. Strawberries were scarcely an average crop; some of the blooms did not set well, a circumstance probably owing to their being exposed to so much wet during the time when they were in flower. Those which did best were—La Crosse Sucriée, Sir C. Napier, Keen's Seedling, Vicomtesse Hélicart de Thury, Fairy Queen, James Veitch, and Frogmore Late Pine. Filberts and Walnuts are a thin crop, and the latter are even now dropping very much.—T. JONES.

Easthampstead Park, Wokingham.—Apricots here are a complete failure, although protected with canvas. Green Gage Plums are very thin. Morello Cherries, too, are thin, but of fine quality. Peaches and Nectarines suffered greatly from blister; they are now making some growth, but are producing a poor crop. We can scarcely look for good Peaches out-of-doors in this locality, as our soil is of a poor, black, sandy character on a bed of clay. A more unfavourable situation for the healthy growth of fruit trees could not have been selected. Great attention has to be paid to root pruning, otherwise the trees soon become barren and sickly. Apples, comparatively speaking, are a failure. Such varieties as Court Pendu Plat, Keswick Codlin, Manks Codlin, Alexander, and Cellini, a

sure bearer, are furnished with a good sprinkling; all other sorts are fruitless this season. Of Pears on walls we have a few on Beurré Diel, Bishop's Thumb, Jargonelle, Vicar of Winkfield, and Winter Nelis. Williams's Bon Chrétien does well as a rule, but like all other standards this year it has failed with us. Strawberries are an abundant crop; our best varieties are Keen's Seedling, which does well, and possesses good quality; President is also a good variety, and an abundant bearer, and British Queen prolongs the season, which at best is a short one. Black Currants are about a fourth of a crop and fine. Red and white abundant. Raspberries are a good crop. Nuts a complete failure.—NEIL SINCLAIR.

Bearwood, Wokingham.—Our fruit crops here are poor indeed. Our best crops are Peaches and Nectarines, although they received no protection whatever. Pears are a fair crop, but Apples and Plums are not at all satisfactory. Small fruits have been very good. Nuts abundant. Everything fully a month behindhand.—J. TEGG.

Welford Park, Newbury.—All out-of-doors fruits in this neighbourhood are quite three weeks later than usual this season. Strawberries and Red Currants are the only crops that have been over an average; the former have been much spoiled by the long-continued rains which we have had. Pears are an average crop, but not likely to be above half the size which they usually are. Apples, Plums, Cherries, Peaches, Nectarines, and Apricots are all far below average; several Peach and Nectarine trees are dead, and many more are looking very unhealthy; on none of the Apple trees is there a full crop; on even the Northern Greening, which seldom fails here, there is a short crop. Some of the sorts set about half a crop, but the fruits soon dropped; they keep dropping even now, and what are left will be very small in size.—CHARLES ROSS.

Cobham Park.—I have forty Peaches and Nectarines on a south wall, and on these there are not more than two dozen fruit, although they were protected with two thicknesses of netting in the spring. Several of them are quite dead, and the others look unsatisfactory. Plums on walls, consisting of Coe's Golden Drop and Goliath, are an abundant crop; the others are a complete failure. I have one standard Orleans Plum loaded with fruit, so much so that it has already split part of the tree off with its weight. Cherries are a complete failure both as regards orchard and wall trees, with the exception of Morellos, which are about a quarter of a crop. Lord Suffield Apples on espaliers are good crops, and Keswick Codlin, Northern Greening, and French Crab are loaded; some others here and there have fruit on them, but others are fruitless. On Pears there is a sprinkling, but on the few sorts that are bearing fruits they are specked; amongst the best are Winter Nelis and Easter Beurré, Glou Morceau, Uvedale's St. Germain, Knight's Monarch, Marie Louise, Dunmore, Louise Bonne of Jersey, Beurré de Capiamont, and Aston Town; these are all well furnished with fruit, which looks, at present, promising. Apricots on walls are a very fair crop; Quinces abundant; of Filbert and Cob Nuts we have very few. Keen's Seedling, Hautbois, and Sir C. Napier Strawberries have borne splendid crops; on Vicomtesse Héricart de Thury there is plenty of fruit, but it is small; La Grosse Sucrée has been very fine, but it is not a heavy cropper; Elton Late Pine has borne fairly well; British Queen a complete failure. Of Gooseberries and Currants of all sorts we have had a very heavy crop. Our soil here is sandy with a gravelly bottom; consequently very poor, but the wet season has been all in our favour.—T. H. BOWLES.

Idsworth, Horndean.—Apples hereabouts are very thin with the exception of Codlins, which generally do pretty well. Pears and Plums are almost a failure, many trees having nothing on them. Strawberries middling. Raspberries are a heavy crop and fruit good. Other small fruits may be set down as average crops. Of Filberts we have heavy crops; Walnuts none. Of Peaches and Nectarines few are grown outside, but such as are are poor. The trees suffered severely from blister, which was succeeded by mildew. Of Apricots, very few are grown in this district, and those few are fruitless. Cherries are a failure; Morellos set well but dropped during the stoning period. Figs are thin crops. On the whole the season has been a most disappointing one as far as fruit growers are concerned. What we want now is plenty of sunshine to help to consolidate the wood for next year. Though the gardens lie high we are tolerably well protected by means of plantations. The natural soil—stiff, flinty material near the chalk, interspersed with beds of clay—is evidently not suitable for fruit, and it is a most difficult soil to work, especially in a season like the present.—N. F. FULLER.

Eaglehurst, Fawley.—Apples in this district are a fair crop, and where the trees were in any way sheltered the crops are abundant, and the trees pretty free from blight as a rule; but some are very much blighted. Of Apricots we have half a crop, and branching is very prevalent this season; some of the most vigorous trees

are the most liable to this disease. Cherries are thin, with the exception of Morellos, which are a fair crop, but all the trees have been infested very much with the black fly, which could scarcely be subdued. Pears are a good crop, notably Williams's Bon Chrétien, Louise Bonne, Winter Nelis, Easter Beurré, Beurré d'Ananlis, and Jargonelles; these had, indeed, to be severely thinned, and are still bearing too heavy a crop. Plums are a complete failure, with the exception of Early Orleans, Winesour, and a few White Magnum Bouums, and these are nearly destroyed by the maggot. Peaches, although there was a good show of bloom, did not set well, and the few that did dropped (as most of the leaves did) through the cold east wind which we had in the end of May and beginning of June. These left the trees completely naked, and I doubt if some of them will ever recover. We had no protection beyond some fish nets, but that was not enough for such a spring as we have had. Figs are a very fine crop, but they will be late; in fact nearly everything is a month later this year than last year. Bush fruits are heavy crops, and free from blight. Strawberries bore a remarkably good crop, but a great many rotted before they were ripe; those that did come to maturity were flavourless.—W. WATSON.

Heckfield, Winchfield.—The year 1879 will, I apprehend, long be remembered as one fraught with blighted hopes as regards horticulture in general and fruit culture in particular. Here at one time we confidently predicted a good fruit year, but alas, frost, snow, hail, rain, and wind were such constant visitants that all trees unprotected have failed to produce good crops, and thus I am surprised that, under the circumstances, there is so much fruit as there is. Apples average about a third of a crop; those that are fruiting best are—Cellini, Keswick Codlin, Lord Suffield, Blenheim Pippin, Golden Noble, Hawthornden, Alfriston, Golden Pippin, Ribston Pippin, Hambleton Deux Ans, and Northern Greening. Apricots well protected on both south and west walls are a fair average crop, but more branches than usual have died off, a circumstance for which the severe winter will account. Morello Cherries are a moderately good crop, but other sorts are thin, and the trees have been badly blighted. Gooseberries and Black, Red, and White Currants were never better, and never had we more of them. Of Strawberries we have had excellent crops, but a great quantity were rendered useless through the constant rain which we have had. President and Vicomtesse Héricart de Thury are the best for this district. Peaches and Nectarines which were well protected are a good average crop but very late; the winter seems to have hit some of the trees rather hard, but most of them are now growing luxuriantly. Pears are a full average crop on walls and a moderate crop on standards and cordons; they were partially protected with evergreen and other branches. The kinds that are bearing most freely are—British Queen, Citron des Carmes, Jargonelle, Seckel, Brown Beurré, Marie Louise, Autumn Bergamot, Beurré d'Amanlis, Passe Colmar, Triomphe de Jodoigne, Beurré Diel, Louise Bonne of Jersey, Beurré Hardy, Winter Nelis, Easter Beurré, Glou Morceau, Beurré Rancee, Ne Plus Meuris, and Josephine de Malines. Plums are very thin; on the majority of the trees, indeed, there are none. On a west wall the following kinds are fruiting fairly well, viz., Green Gage, Diamond, Coe's Golden Drop, Kirke's, Jefferson, and Pond's Seedling. The soil hereabouts is light and sandy in character, inclining to peat, with a substratum of gravel and sand.—W. WILD-SMITH.

Stratfieldsaye, Winchfield.—Fruit crops here, and as far as I have been able to learn, in the neighbourhood, are at best very partial. Of Apples, some trees are bearing heavy crops, while many others are quite barren. Altogether I may have a third of a crop. Keswick Codlin, Cellini, Duchess of Oldenburg, Northern Greening, and King of the Pippins, all useful varieties, seem to withstand adverse seasons the best, as I have scarcely ever seen them fail. Pears on walls and espaliers are a fair crop, but they are very thin on standards. Nothing could have been more promising up to the 11th of May, as the blossoms were plentiful and strong; but 12th of frost on that night destroyed almost every bloom which was unprotected. Cherries bloomed abundantly, and seemed to set well, though only to fall off somewhat later, a remark which also applies to Plums, with the exception of the Victoria. Apricots are abundant, and promise to be fine in quality though much later than usual. Peaches and Nectarines where protected are carrying heavy crops; the trees, too, are quite free from gum and perfectly healthy. If further proof were wanted as to the advantages of covering the trees with good warm material, not only during frosty nights, but every night up to at least the 1st of June, I have an example here which would at once convince the most credulous. It being intended to use part of a Peach wall for another purpose, the trees, not being required, were left unprotected. Though kept clear of insects, they are now almost as destitute of leaves as they are of fruit, whilst all which were protected are as healthy and as fruitful as could be desired. Gooseberries are very scarce, but Currants of all kinds and

Raspberries are most abundant. Strawberries were a very heavy crop, but quantities of the fruit were spoiled by the continual rains which we have had.—J. BELL.

Hackwood Park, Basingstoke.—The fruit crops in this and in other gardens in the neighbourhood are, I am sorry to say, not encouraging. The almost unprecedented wet, cold spring and summer which we have had, accompanied with little sunshine, has been very unfavourable for setting and after-maturation. Fruits this season, in some instances, are very watery and poor in flavour, especially Strawberries and Raspberries, which are from three to five weeks later than last year. The soil generally is a clayey loam resting on a subsoil of clay and chalk. Of Apricots we have but few, and late Plums are under an average. Of Peaches and Nectarines we have very few. Apples are thin and small, and are falling off the trees in quantity. Of some kinds of Pears we have a good average. Currants and Gooseberries are an average crop. Strawberries and Raspberries under an average. Filberts and Nuts a thin crop, and of Walnuts we have none.—THOS. EAST.

Eridge Castle, Tunbridge Wells.—Apricots in the gardens here are scarce. Peaches half a crop. Pears plentiful and good. Apples and Plums average crops. Strawberries abundant. Raspberries excellent. Gooseberries very fine. Currants plentiful. Nuts over an average. Figs abundant. I have upon the whole to report favourably on the fruit crop. Our garden lies 400 ft. above the sea without shelter, and the prevailing winds are south-west. The soil is a stiff loam resting on a natural incline to the south. All kinds of fruit trees prosper with us, except the Apricot, which fails from want of chalk in the soil, and the Peach from want of shelter, natural and artificial. Pears such as the Doyenné d'Été, Lammas, Beurré Giffard, Williams's Bon Chrétien, Beurré d'Amanlis, Seckel, Louise Bonne of Jersey, Swan's Egg, and Beurré Bose, do well on standards, and Marie Louise, Passe Colmar, Forelle, Knight's Monarch, Bergamotte d'Espereu, Josephine de Malines, Glou Moreceau, Jean de Witte, Napoleon, Ne Plus Meuris, Bezi Vaet, Pitmaston Duchess, Zéphirin Grégoire, and many others succeed well on walls. Apples of all kinds do well, but I would call attention to an Apple grown largely in this locality, viz., Golden Knob. It keeps good till May, and is altogether an excellent variety.—J. RUST.

Linton Park, Maidstone.—Fruit crops in this district are by no means good; Apples in the majority of orchards are but a very thin crop; they flowered magnificently and very late, but drenching rains and cold ungenial weather have only left a very meagre crop except in the case of a few kinds such as Keswick Codlin, Stone's Apple, and other free bearing kinds. The soil here is excellent for fruit trees, viz., a rather strong tenacious loam resting on broken stone called hassock, a soft porous stone which retains moisture in dry seasons and acts as drainage in wet ones. Common orchard Pears such as Lammas, Williams's Bon Chrétien, Ashdown Park, and Swan's Egg, are heavy crops, but good winter sorts are thin. Plums are variable; Damsons in some places are a good crop. Cherries are nearly a total failure, the only exception being Morellos, which are very largely grown on cottagers' walls and out-buildings hereabouts, and as they always sell well the produce of such trees often pays the rent of the cottage. Peaches and Nectarines on walls are a fair crop and the trees healthy; in fact, in this soil they grow rather too luxuriantly without the aid of stimulants, and the same remark applies to most wall trees in our enriched kitchen garden soils. Wet and dull sunless seasons predispose the trees to leaf and wood growth rather than to the production of stubby fertile spurs such as one likes to see. Bush fruits generally are a fair crop and very largely grown hereabouts: some plantations of Gooseberries are bearing very heavy crops; Currants moderate ones; Raspberries heavy; and Strawberries have been a good and lasting crop, although many rotted through excess of moisture. We grow Vicomtesse Hélicart de Thury, Keen's Seedling, President, Sir C. Napier, James Veitch, and Traveller, all of which have borne heavy crops. We use Sir C. Napier for preserving and culinary purposes as it is bright and of brisk flavour, in fact, acid in dull sunless seasons, but good for desert when well ripened. We find 3 ft. between the rows and 2 ft. from plant to plant none too much space for Strawberries. Filberts and Cob Nuts are at present looking well and promise to be fine crops; they are largely grown hereabouts between standard Apple and Pear trees and sometimes on hill sides, but in all cases they are pruned so as to keep them in the form of dwarf very wide spreading bushes, the whole of the central shoots being cut away after the manner of Red Currants, and only the small spray-like growths retained on the main shoots at the winter pruning. The ground amongst them is dug and manured and kept clean in summer, and the result is bunches of Nuts that look like quite a distinct fruit compared with that produced by unpruned trees. At present I may safely say that in spite of adverse seasons, fruit culture is rapidly extending, as the price of fruit in market and the increasing demand for it for preserving purposes render it, if not

a very profitable, at least a safe investment where the soil is so well adapted to yield good returns.—J. GROOM.

Dropmore, Maidenhead.—The fruit crop in most places near here is very inferior with the exception of small fruits, such as Strawberries, Gooseberries, Raspberries, and Currants, all of which are good, and the same may be said of Nuts, which are unusually good. Walnuts are nearly all falling off; every fruit is much later than I have ever known it to be. Apples are very scarce, and these are all more or less dropping on all kinds of soils; there never could have been a more splendid show in the early part of the season, but the long continuance of rain and sunless weather prevented the fruit from setting freely; we had no frost to do the least damage, and the wall fruits, which are very thin in most places, did not require protection in the early season, but set badly. The kitchen garden here is composed of a good loam (brick earth), and the crops are remarkably good with the exception of wall fruits, which are under an average. On some light soils and in exposed situations the crops are much inferior. Cherries set but fell off, and the crop is an indifferent one in all the orchards hereabouts. The subsoil, with a few exceptions, is mostly gravel. Fruit growers complain sadly and not without good reason.—P. FROST.

Petworth Park, Petworth.—Early Apples, such as Codlins, Hawthornden, and Nanny, are fair crops, but keeping Apples are very thin in this part of Sussex. Apricots are abundant under glass copings, but very few on open walls. Cherries are quite a failure; a heavy crop set, but all fell in stoning, or cracked and rotted on the trees. Plums are very thin on standards and pyramids; on some sorts on walls there is a fair crop, but generally they are indifferent. Damsons are plentiful. Peach trees are in very bad condition; I have seen many quite killed where they were not well protected in the spring. My Peaches and Nectarines are looking fairly well, considering the cold wet season, under glass copings, and are bearing good average crops of fruit, but very backward. They have made no good wood at present, and unless this month proves more favourable than the last, they cannot ripen their fruit this year. Pears set well, the weather being dry, though so cold, when they were in bloom, but the fruit still is miserably small, hard, brown, and cracking now that we are having a little warmer weather. I fear Pears will be a poor crop—the skin seems so tough they cannot swell. Currants, Gooseberries, and Raspberries are abundant and very fine, but not well flavoured. Many sorts of Gooseberries are not ripe yet. Strawberries have been abundant, but half of them have been spoiled by the continual wet weather which we have had. During the past week we have gathered some good fruit, and it has been much better flavoured than heretofore. Nuts and Filberts plentiful. Walnuts thin. Figs a very poor crop. Outdoor Grapes very bad.—G. BREESE.

SOUTH MIDLAND DIVISION.

Latimers, Chesham.—Apricots are an average crop hereabouts; Plums and Cherries under average; Peaches and Nectarines bad, trees almost killed; Apples and Pears under average; Red, Black, and White Currants are average crops; Strawberries abundant; Filberts an average crop.—A. DONALDSON.

Blenheim, Oxon.—I have to record another season of disappointment, although at one time so full of promise. Apples are partial. We have very few Blenheim Pippins in this their native home; Wellingtons, too, are thin; Hawthornden, Stirling Castle, Cellini, and Atkin's No. 2 are better, but the trees are much blighted. Pears, too, are but a medium crop; old Bergamot, Jargonelle, Louise Bonne, Beurré Magnifique, and Glou Moreceau notably so. Apricots, where protected by Parham's coping, &c., are good crops, otherwise thin. Plums are a fair crop, especially Damsons. Bush fruits of all kinds are good crops, and of an average quality. Strawberry crops were very heavy, especially Vicomtesse Hélicart de Thury, President, and Sir Joseph Paxton, although many were spoiled by the weather. Cherries are very poor and nearly all split. Our soil is a strong limestone, but we have had too much rain even for this. Black and green fly have been unusually troublesome; wasps and birds much less so than usual.—WILLIAM CRUMP.

Moorpark, Rickmansworth.—Fruit crops here and in this neighbourhood are considerably below the average, with the exception of bush fruits—Raspberries, Currants, Gooseberries, and Strawberries, which are heavy crops; of the last a great many got spoiled by the wet. The variety from which I gathered first was La Grosse Sucrée; this came into fruit in March, and lasted till the 7th of July. We picked from the houses from 1 lb. to 1½ lb. per day. The fruit has been very fine. I am now gathering fine fruits from Helena Gloede and Unser Fritz; most of the others, about twenty varieties, are still bearing small fruits. I think Oxford Hall will prove a grand Strawberry, and that it will be largely grown when better known; it bears large fruit, the flesh is firm, the flavour

good, and the plant appears to have a good habit and constitution. Apricots under Rendle's protectors are heavily cropped, while trees on south-west and east aspects are very thinly furnished with fruit. The trees have died back very much, and the fruit dropped prematurely; I shall by degrees shorten back the spurs, which now project nearly 1 ft. from the wall. The fruit is chiefly to be found on wood laid in close; the spurs blossom profusely, but being exposed it got cut off. The trees were all protected when in blossom by a thick woollen covering. Peach and Nectarine trees almost destroyed by blister, are now recovering fast, and are bearing a fair sprinkling of fruit. On Cherries and Plums there is a fair crop; Damsons are a heavy crop. Apples and Pears middling; on pyramids the fruit looks unkindly; it is cracking, and the trees are stunted. Our soil is very light, on gravel and chalk.—J. C. MUNDSELL.

Ramsey Abbey.—Peaches and Nectarines are a fair crop. Apricots only moderate. Plums very thin, only two kinds of the latter, viz., Victoria and Orleans, are bearing full crops. The only protecting material used here this year has been Yew branches, which appear to be quite as efficient for Peaches and Nectarines as more costly coverings. Apricots would, I think, have been better with something heavier, as the blossoms will not survive wet and cold in the same way Peaches do. With reference to stone fruits I think it is quite as important to keep the trees clean and the young wood thin, and freely exposed in summer, as it is to protect blossoms in spring. If the flowers are weakly they will not set well, no matter how protected. Apples and Pears are thin; except in the case of a few trees of Codlins, the Apple crop may be pronounced a failure, and especially so as regards large trees in orchards. The dwarf trees are this year doing best. Bush fruits and Strawberries are most abundant and fine. Cherries, even including Morellos, are thin and poor. Open-air Grapes cannot ripen, and Figs must be late. Filberts are a fair crop. Walnuts very partial, but mostly scarce and small.—E. HOBDAV.

Wycombe Abbey.—Apricots here are considerably under the average, and the trees are much disfigured through the loss of branches; they had protection in the spring months in the shape of canvas coverings. Plums are scarcely an average crop, but pretty equally distributed amongst such kinds as Victoria, Coe's Golden Drop, Diamond, Kirke's, and Jefferson. Green Gages are very scarce. Of Cherries we have a fair crop; the light-coloured sorts, such as Bigarreau, Governor Wood, and Bigarreau Napoleon, where not protected from such an excessive amount of moisture as we have had, are rendered almost worthless through cracking; we find that the Elton resists the effects of moisture better than any other light-coloured variety. As to Peaches and Nectarines, although they set well, the crop now is so diminished as to bring it below an average one; this may, in a great measure, be attributed to the baneful effects produced by blistering, which has been worse here this season than it has been for the past twenty years. Apples are a good average crop on such sorts as Codlins, King of the Pippins (very abundant), Cox's Orange Pippin, Wellington, Kentish Filbasket, Rosemary Russet, and Allriston; present appearances indicate small fruit as the ultimate result. Pears on walls are a very abundant crop, which promises to be of average size; on standards the crop is lighter. The best kinds here, considering both quality and usefulness for a successional supply, are Williams's Bon Chrétien, Jargonelle, Louise Bonne of Jersey, Beurré de Capiaumont, Fondante d'Automne, Marie Louise, Williams's Duchess, Duchesse d'Angoulême, Passe Colmar, Huyshe's Victoria, Doyenné du Comice, Beurré d'Areberg, Winter Nelis, Zéphirin Grégoire, Josephine de Malines, Knight's Monarch, Glou Morceau, Easter Beurré, and Beurré Rance; the above varieties usually come in with us in the order in which they are named. Raspberries, Gooseberries, and the different kinds of Currants are average crops, but with the exception of the Raspberries all are deficient in flavour. Strawberries were abundant, but not equal in size or quality to those of ordinary years. I may say without fear of contradiction that Vicomtesse Héricart de Thury is the most useful and best flavoured variety extant for general purposes, and President may be placed next to it. Nuts are an average crop. In the surrounding neighbourhood the Apple crop is below the average; so also is that of Cherries and Plums. Damsons are more abundant, and small fruits are tolerably plentiful.—GEO. TITOS, MILES.

Great Tew Park, Enstone.—Here, as in most other localities, we have passed through a trying ordeal; but, taking the wet, cold, and sunless season into account, I must say that several of our crops have turned out better than I anticipated. Black Currants have been good, and extra fine in quality. Red and White Currants are a good even crop, but very much infested with caterpillar, for which we find nothing better than hand-picking. Raspberries are a good crop, and have made fine growth. Gooseberries are only half a crop, bullfinches having eaten the fruit buds last spring. Strawberries, upon the whole, have been a light crop; our favourite

variety is Hooper's Seedling, which appears to be an improved Keen's Seedling; it is a good cropper, fine in flavour, and, as a rule, can be depended upon. We also like Newton Seedling and Prince of Wales. Wall fruits are a partial crop. Pears have succeeded best with us on a west wall; those that have done best (trained on the upright cordon system) are Napoleon, Williams's Bon Chrétien, Beurré Hardy, Doyenné d'Alençon, Beurré du Comice, Fondante d'Automne, and Beurré d'Amanlis. Twelve Apple trees on the same wall are almost a failure. Pears on an east wall that are carrying good crops are Napoleon, Winter Nelis, Bergamot d'Esperen, Thompson's, Louise Bonne, Doyenné d'Eté. Plums both on east and west walls are a partial crop; we have a fair sprinkling of Green Gages. Cherries, with the exception of Morellos, have been a light crop; all our Cherry trees have suffered very much from black fly this season. Apricots on the south walls are quite a failure, although we took the precaution to cover them with No. 5 shading, a fine warm, light fabric. As usual, our orchard-house is a great success, and has been for these last thirteen years. I almost omitted to state that Apples are quite a partial crop in this neighbourhood.—JOHN MELVILLE.

WEST MIDLAND DIVISION.

Warwick Castle.—The fruit crops in the gardens here are, as a rule, very scant. Small fruits, such as Red and Black Currants, have not been an average crop, the former better than the latter; but what we had have been fairly good. Gooseberries have been very scarce; Strawberries a fair crop, but few arrived at perfection, the greater portion rotting before they changed colour. Apples on many trees set fairly well, but the majority of them have fallen since; on some few trees there is a fair crop left. Pears are very partial; some few trees are bearing a fair sprinkling. Plums are a very partial crop, and the trees are smothered with black fly. Cherries set well, but black fly damaged the trees so much that the fruit fell off. We have but a few trees of Apricots, but on these we have good crops. Fruit is very partial, so far as I have seen in this neighbourhood. The soil in which our trees grow is a light one, resting on gravel; some portions of the ground rest upon a freestone or soft rock. Rhododendrons flourish well on the top soft sand of the rock. Our garden suffers from gales of wind from the west or west by north.—DANIEL JUDD.

Tortworth Gardens, Falfield.—Fruit crops in this district at one time promised to be abundant, but the weather continued so excessively wet and the temperature low when the greater part of the trees were in bloom, that the result is only partial crops. Apples with us are an average crop, the later kinds being much the best, although there is a fair crop on some of the earlier kinds. Cellini, Beauty of Kent, Cox's Pomona, Hawthornden, and Keswick Codlin, where somewhat sheltered, are abundant, and the same may be said of Lord Suffield, Manks Codlin, and Stirling Castle. The latter is a great favourite here, and should be in every collection, however limited. Dessert kinds, such as Reinette du Canada, Golden Harvey, Lord Burghley, Royal Russet, Cox's Orange Pippin, Melon Apple, Pine-apple Russet, Court of Wick, Ribston Pippin, Golden Pippin, Kentish or Vaun's Pippin, Cockle Pippin, Duke of Devonshire, Pearson's Plate, Lodgemore Nonpareil, Wormsley Pippin, Worcester Pearmain, King of the Pippins, Sturmer Pippin, Brad-dick's Nonpareil, Northern Spy, Claygate Pearmain, and Adams's Pearmain, are all bearing a few fruits, mostly on the sheltered side. I find that the more exposed parts of the trees are casting their fruit, which, I think, must be owing to imperfect fertilisation. Pears are quite an average, and promise, so far, to be very good. I notice full crops of Beurré Duhaume, Anna Nelis, B. Sterckmans, B. d'Amanlis, B. Goubalt, B. Diel, B. Leonie Clere; a few on B. Bachelier, Bon Chrétien, Comte de Lamy, Conseiller de la Cour, Chaumontel, Duchesse d'Angoulême, Doyenné du Comice, Doyenné d'Eté, Eye-wood, and Fondante de Malines. Josephine de Malines is the best late Pear grown here. Many other kinds are bearing a few fruits. Apricots are much under average. Plums are fair average crops, but dropping very much through the ravages of the Plum maggot. Peaches and Nectarines are very poor. Bush fruit abundant, but sadly damaged by the caterpillar in spite of all means to keep it in check. Strawberries have been a fine crop, but wanting in flavour. Filberts and Cob Nuts abundant and very promising. Cherries very good. Quinces and Medlars partial crops. Cider Apples are very thin indeed hereabouts.—THOMAS SHINGLES.

Madresfield Court, Great Malvern.—The unusual coldness of the season up to the end of July, combined with an almost continual rainfall and little sun, has had a most prejudicial effect on fruit crops generally, and all kinds are here fully a month late. The bloom generally was good, but from the causes just mentioned it set imperfectly. Apples are very thin; Pears a fair crop, very good here on walls and pyramids, but late. Apricots moderate; Peaches and Nectarines a full crop, but great difficulty has been experienced in

keeping the trees clean. Plums are a moderate crop; such kinds as Victoria, Rivers's Prolific, and Magnum Bonum are bearing most freely. The best dessert kinds on walls are very thin. Bush fruits are a moderate crop, clean and fine; Raspberries unusually good. Strawberries abundant, but small and lacking flavour. Nuts abundant; Walnuts have nearly all dropped. Figs on walls are a fine crop. With a continuance of favourable weather, such as we are at present experiencing, there may be time for the late fruits to ripen, but even under the best of weather there will be neither the size nor quality which we usually get in good seasons.—WILLIAM COX.

Eastnor Castle, Ledbury.—Fruit trees of all kinds in this locality up to the blooming period gave promise of abundant crops, but a continuance of cold rain and an absence of sun during the time they were in flower paralysed the sap and washed the pollen into paste; the result is, partial crops of imperfectly fertilised Apples, Pears, Plums, and Cherries. Amongst Apples we find the Old Keswick Codlin, Lord Suffield, Lord Grosvenor (a fine early kitchen Apple), Ecklinville, and Hawthornden, bearing good crops. Ribston Pippin and other choice dessert kinds are thin, and cast their fruit. Pears on walls are plentiful, but very late. Jargonelle, Williams's Bon Chrétien, Pitmaston Duchess, Crassane, Beurré d'Amanlis, Passe Colmar, Belle de Noel, Maréchal de la Cour, and Josephine de Malines, have required thinning; the fruit is clean, and is now swelling nicely. The kinds of Plum usually grown on walls are a fair average crop, but standards and pyramids are still casting their fruit, the cold weather having been so much against the stoning of imperfectly set fruit. Apricots are about half a crop; trees clean and free from weevil. Red and White Currants abundant, and very fine. Black Currants injured by frost, and badly blighted. Raspberries plentiful, fine but deficient in flavour. Strawberries on high ground have been abundant; in low situations the flower-stems were injured by the cold rain. With us, Paxton, President, and La Grosse Sucrée have produced fair crops of fruit. Of late kinds, Oxonian, Elton, and Frogmore Late Pine, are just coming in, and in the event of the weather continuing fine, these useful old varieties will give a supply of fruit up to the end of the month. The Queen section have not done well. Damsons and Nuts are a heavy crop. Soil a heavy calcareous loam, thoroughly drained, and well adapted for stone fruits. I have nearly overlooked Peaches and Nectarines, of which we have excellent crops. The trees are clean, free from blister, and, where lifted last autumn, the foliage looks dark and healthy. Trees that were not lifted look pale, and show signs of having suffered. We use glass copings, 2 ft. wide, from the time the flowers begin to open until danger from spring frosts has passed away. Formerly, in better seasons than we have had of late, we had many blistered leaves and gouty shoots, but the use of glass copings has completely stopped it. In this low-lying garden we are obliged to keep the roots within bounds, and lift every second year. Potatoes of all kinds are badly affected with disease; three-fourths of the tubers of early kinds that we have taken up are tainted, and having been caught before they were ripe they are waxy and flavourless. The disease first appeared under glass in March, when it attacked and destroyed fifteen lights of forced Potatoes.—W. COLEMAN.

Drayton Manor, Tamworth.—Apples, Apricots, Pears, Cherries, and the best varieties of Plums are again a failure; but the following are exceptions, viz., Lord Suffield, Hawthornden, Northern Greening, all varieties of Codlins, and also Worcester Pearmain. This variety will become a general favourite; it is evidently an Apple that may be relied on for a crop of medium-sized handsome fruit. Dessert Apples generally are conspicuous by their absence. Pears are not quite so scarce as Apples; the following are bearing fair crops on walls, viz., Beurré Diel, Beurré d'Amanlis, Beurré Magnifique, Brown Beurré, Baronne de Mello, and Glou Moreceau; on espaliers and pyramids—Williams's Bon Chrétien, Marie Louise, Beurré Clairgean, Aston Town, and Seckel. All the above are producing satisfactory crops. I might especially mention Baronne de Mello as being one of the best flavoured and surest croppers of all Pears on walls, it having never failed to furnish a first-class crop here for the past fifteen years. Apricots are very light, and, what is much worse, the trees are dying wholesale, young healthy trees too. Nurserymen, I fancy, may anticipate a brisk trade in these during the next planting season, as I believe the complaint to be general. Cherries have been very light, also Plums with the exception of Denyer's Victoria, Kirke's, and Green Gages on walls, which are good. Damsons are unusually abundant. Currants not quite so plentiful as usual. Strawberries and Raspberries good, but the former damaged by much rain and dull weather. Kitchen garden crops generally are looking well, but quite five weeks later than usual.—O. THOMAS.

Crew Hall.—Although this has been a most exceptional and trying season, not only as regards the severity of the past winter and coldness and lateness of the spring, but also as respects the cold,

and wet summer which we have lately had, fruit on the whole in this district is rather above the average, but everything is a month later than usual. Should the remainder of the season be warm, dry, and otherwise favourable to the ripening of fruits, those which have still to ripen may be as good in quality and quantity as the average of seasons, otherwise much will be small and unripened. Owing to the absence of frost at the time when fruit trees were in bloom and the fruit setting, trees in situations sheltered from cold winds, as ours are, had a large quantity on them, but the subsequent cold temperature and excessive wet caused much of the fruit to fall. Still there is rather more than an average crop of Apricots and Peaches. Apples, Pears, Plums, and Cherries are average crops, and of Damsons we have had the largest crop which we have had for several years, a circumstance which in this county is important, as they are very largely grown. We have had plentiful crops of Nuts, and good crops of all small fruits except Strawberries. These blossomed and fruited well, but the heavy rains caused many, both of the growing and ripe fruit, to rot; therefore the crop has been less in quantity and inferior in quality to what it would have been had the weather been favourable. It was also very late in ripening. In exposed situations Black Currants are scarce, the cold winds having injured them. Wall fruits with a few exceptions are good average crops but late, and will require a fine dry autumn to ripen well. The kinds of fruits which I have found to do best out-of-doors this season are: Peaches—Hale's Early, Dr. Hogg, Alexandra Noblesse, Dymond, Violette Hâtive, Sulhamstead, Prince of Wales, and Stirling Castle; Nectarines—River's Orange, Elruge, Lord Napier, and Violette Hâtive; Plums—Victoria, Kirke's, Early Orleans, Thornhill's Seedling (a local kind), and Green Gage; Pears—Citron des Carmes, Jargonelle, Louise Bonne, Marie Louise, Winter Nelis, Glou Moreceau, Winter Doyenné, Josephine de Malines; Apples—Irish Peach, Lord Suffield, Keswick Codlin, Hawthornden, Worcester Pearmain, Minchall Crab, Cox's Pomona, Catshead, Dumelow's Seedling, and Ribston Pippin; Strawberries—Keen's, Vicomtesse Héricart de Thury, President, James Veitch, and President de la Cour.—W. WHITAKER.

Witley Court, Stourport.—This is, doubtless, one of the most unfavourable seasons on record as regards fruit culture. In spite of the profuse blossom which we had upon all kinds of trees, the fructification lacked vigour, the embryo fruits falling in showers. Apricots are very partial, many trees suffering from the low state of the ground temperature, whole branches in many instances dying off. Plums are in many instances heavily cropped. Damsons are bearing abundant crops, and so are such kinds as Victoria, Rivers's Early Prolific, and the Pershore. Belgian Purple and Prince Englebert are also two of the most reliable of Plums for all seasons, and they are bearing freely this year. Prince of Wales, Jefferson, and Denniston's Superb are also carrying good crops. Peaches and Nectarines have suffered much from curl, many trees being quite killed, or so disfigured as to warrant removal. Apples are partial, and the trees, so far, are making unsatisfactory growth. To mention particular sorts that are bearing crops this season would be somewhat invidious, as they are generally bad. Pears, although more plentiful, are by no means satisfactory, and I fear, except we have a particularly long and favourable autumn, that their quality will be but indifferent. Amongst those that are bearing the largest crops are Williams's Bon Chrétien, Autumn Bergamot, Beurré Bosc, Beurré d'Aremberg, Beurré Sterckman's, Louise Bonne of Jersey, Maréchal de la Cour, Marie Louise, Seckel, Bergamotte d'Espérance, and Uvedale's St. Germain. Cherries are very partial and poor in quality. Gooseberries are under the average, but they are good in quality and the plants are healthy. Black Currants are a poor crop, and the bushes are much blighted. Red Currants are an average crop. Raspberries abundant. Amongst the best are Prince of Wales, Fastolf, and Antwerp (red). Mulberries are heavily cropped; Walnuts a failure; Filberts abundant. Strawberries have been plentiful and of fair quality considering the wet weather. Such as were supported on branches coloured best, and were free from slugs, which are so troublesome this season. The best cropping kinds are President, Pioncer (a fine early kind), British Queen, Lucas, Sir Joseph Paxton, Dr. Hogg, and James Veitch.—J. WESTLAND.

Downton Castle, Ludlow.—The fruit crop, taken as a whole, presents in this neighbourhood a fair average, taken in comparison with that of former years. Although the late frosts which marked the termination of an unusually cold and backward spring destroyed to some extent the very favourable anticipations which had been formed concerning the Apple crop, nevertheless there is every reason to believe that in this district at least the harvest of cider Apples will be fully up to the average. A late spring, and an almost sunless summer have had the effect of leaving this, in common with all other fruit crops, fully a month later than usual. Bush fruits of all kinds have been excellent. Currants, black, red, and white, have borne in this neighbourhood unusually heavy crops. The

same remark applies to Gooseberries; while the crop of Raspberries has been far above the average. Of wall fruits there are fair crops of Pears, Plums, Cherries, and Apricots. Peaches (outdoor), as might have been expected from the character of the season, will not be good. The crop of Filberts promises to be the best that has been known for many years; but the Walnut crop in this neighbourhood is a complete failure. Strawberries were very late, and though most kinds set well, the excessive wet had a very injurious effect upon the unripe fruit, causing great numbers to rot before attaining maturity. The soil which predominates in this district is a stiff clayey loam, of no great depth, resting on a foundation of dark sandstone. The fruit garden at Downton slopes gently to the south, and is partially protected from the north. The principal kinds of Apples grown here are Blenheim Orange, Mère de Ménage, Northern Greening, Wormsley Pippin, Keswick Codlin, and Devonshire Red. Of Apricots, which are good where protected, we grow Moor Park, Breda, and Kaisha. Of Nectarines we grow the Murray, Downton, and Elnage. Of Peaches, the Noblesse, Royal George, Early Alfred, and Barrington.—C. SLADE.

NORTH MIDLAND DIVISION.

South Rutland.—With some very few exceptions only my own orchard trees and those of my neighbours have suffered, more or less, from the unfavourable state of the weather during the spring and early summer months. A season more promising at first I can scarcely recall, but a change came over the trees when they ought to have been setting their fruit, and the dire effects of protracted wet and cold were soon painfully exhibited. Apples that are here usually counted by hundreds will scarcely be counted by tens; the healthiest tree I have is one whose name I do not know; it belongs to the class of culinary Apples, of which Cox's Pomona is one, and to which it bears a resemblance, only it has not its brilliancy of colour. The leaves are large, of a dark green colour, and glossy; the shoots are strong and vigorous, and they are pale green, and somewhat glaucous at the points; it is a large Apple, and of better flavour than Cox's. Irish Peach Apple has suffered but little, and has nearly its complement of fruit; Blenheim Orange, Rutland Foundling, Waltham Abbey Seedling, and Cellini, can boast of a few Apples here and there to be seen among the branches; but of the rest most have not a single fruit, and some are almost leafless, such as Court Pendu Plat, Cox's Pomona, Orange, some of the Pearmain, Bess Pool, Reinette du Canada, and Wyken, Keddlstone, and Ribston Pippins. Of Pears, those that have defied the weather here are Beurré Diel, Winter Nelis, Swan's Egg, Louise Bonne of Jersey, Williams's Bon Chrétien, and Doyenné Boussoch, most on south or west walls; Glou Moreceau and Josephine de Malines have very slender crops; Marie Louise seems to have suffered most of all. Plums in general have done well. I have three sorts that are loaded with fruit, Rivers's Early Prolific, Denniston's Superb, and one that I have named the Zulu, about which I hope to tell you more when the fruit ripens. Rivers's Early Favourite and his Autumn Compote, Jefferson, Washington, Guthrie's late Green Gage, Diamond, and Prince of Wales, have nearly their usual amount of fruit; Green and Purple Gage hang rather thin on the trees. Damsons are very plentiful, and so are Filberts and small Nuts, but Walnuts will be very scarce. Cherries have not been so plentiful as usual with us. Our soil is light and well drained. The rain would have done us no harm had the soil been sufficiently warmed by the sun's rays.—B. S.

Belvoir Castle, Grantham.—A late season, by retarding the blossoming of fruit trees, is often a favourable one in regard to crops; but the present season is altogether an exception to the above rule. The season is the latest I ever remember, and the failure of anything like satisfactory crops of fruit is general in this district. Our orchards are on the lower Lias clay, the surface modified in a degree by cultivation, but in its compact form still within reach of the roots of fruit trees. The cold and wet weather has therefore operated most injuriously on the trees, checking root action, and causing a very fair show of blossoms to fall off. The Apple crop is the worst I can remember, a few trees near buildings alone bearing satisfactory crops. Hardly and delicate kinds have suffered equally, and the foliage is yellow and unhealthy, giving rise to apprehensions as to the succeeding year's crops. The above remarks apply to our orchards. Within the walled garden, where the soil has been made, a better state of things exists. Pears on walls are bearing fairly well—the ripening of the fruit is another matter. We have Beurré d'Été, Jargonelle, and Williams's Bon Chrétien with good crops; Beurré d'Amanlis, Beurré Superfin, Beurré Suprême, Josephine de Malines, Knight's Monarch, Shobden Court, and Doyenné Boussoch showing a fair promise of fruit. Apricots are about an average crop, but will not be ripe until September according to present appearances. Peach trees on south walls were seriously injured by March winds, and though struggling into growth will never fairly recover.

Wall Plums are thin; some standard trees of Orleans, Prince Englebert, and Winesour are heavily laden. Morello Cherries on prepared soil are much blighted, but will afford a partial crop. Strawberries have suffered much from the frequent heavy showers, or the crop would have been abundant. Raspberries are sufficiently productive, and Currants have produced moderately good results. Gooseberries are thin; the lateness of all these fruits is remarkable. Frognore Late Pine Strawberry will probably prolong the supply until September.—WM. INGRAM.

Cole Orton Hall, Ashby de la Zouche.—Apples and Pears bloomed and set well, but owing to the wet, cold weather, they have nearly all dropped off. The soil was so cold that the trees had not energy sufficient to support the fruit. Strawberries promised to be very plentiful, but the greater part damped off at the flower stalk after they were half grown, and what did ripen were not well-flavoured. Of Cherries we have a few on walls of good quality, but they are a thin crop generally. Plums here and in the immediate neighbourhood are a poor crop, but in some places they are plentiful. Peaches and Nectarines are a fair crop, but I fear they will never ripen. Small fruits of all sorts are plentiful, except Raspberries, but they are rather small. Figs are very plentiful, but I doubt they will never come to perfection. Apricots are very scarce, but good crops of them may be found in the district. Of Nuts we have half a crop. This year has been most disappointing and disastrous. Early in the season every one thought we should have a great fruit year. The trees were like nosegays, so plentiful were the blossoms, but nothing could withstand such weather as we have had.—M. HENDERSON.

Aswarby Park, Folkingham.—The soil here is a cold, heavy, black loam, resting on strong blue clay full of water. Out of about fifty varieties of Apples Lord Suffield is the only one that is carrying a full crop. Orchards that ought to have produced from 200 to 800 pecks of Apples will not yield more than from 20 to 50 pecks. Peaches and Nectarines are a complete failure. They looked well up to the last week in June, when they were struck with some blight that completely paralysed the trees. They shed their foliage in two days, leaving nothing but the fruit on the trees, and in less than a week the whole of the fruit fell off, and most of the trees seemed to be three parts killed, and some of them are quite dead. Of Apricots and Figs we have full crops. Of Pears the following varieties are bearing nearly full crops, viz., British Queen, Princess Royal, Broom Park, Hacon's Incomparable, Althorp Crassane, Beurré de Piequery, Glou Moreceau, Knight's Monarch, Winter Nelis, Beurré Bose, Crassane, Basiner, Marie Louise d'Uccle, Joly de Bonneau, and Ne Plus Meuris. Strawberries have been a most abundant crop but deficient in flavour. Our varieties are Keen's Seedling, Garibaldi (true), Sir Joseph Paxton, and British Queen. Of Gooseberries, Red Currants, and Black Currants we have full crops, and the fruit is very large. Plums and Walnuts are a failure.—RICHARD NISBET.

Lenton Hall, near Nottingham.—We are two miles from Nottingham in a south-westerly direction, and we occupy an elevation equal to that of Nottingham Castle. Our soil is mixed, as we are on the edge of a "fault;" one part, that lying towards Wollaton and Nottingham, is light, on the Nottingham sandstone; the other strong, viz., that lying towards Derby and the Trent. The garden is on both soils; the orchard on the strong exclusively. We are well sheltered by trees on all sides. In the orchard Apples are a poor crop on old and high trees, but younger and lower ones are growing and bearing fairly. The same remarks apply to Pears. Plums are a fair crop. Damsons not so good. Of Walnuts we have comparatively none; but Cobnuts are a good crop. Apricots are a fair crop, and the same may be said of Peaches and Nectarines. Plums, too, are a fair crop on both walls and bushes. Pears on walls are poor, but a fair crop on pyramids and bushes. Gooseberries and Raspberries are full crops. Strawberries good; but deficient in flavour. Black Currants poor; they became honeydewed and fell off heavily before they were quite ripe. Red and White Currants are a fair crop. In short, our fruit crop is on the whole moderate.—N. H. POWNALL.

Thoresby, Ollerton.—Of Apricots we have about half a crop, and of Apples very few; Pears are an average crop. Of the finer sorts of Plums we have not many, but Damsons and Mirabelles are fair average crops. Gooseberries are plentiful and fine. Strawberries abundant and the fruit large. Currants—Red, White, and Black—are plentiful. Raspberries abundant and fine. Filberts, being in a sheltered situation, are plentiful. Of small fruits in general we have good crops in this neighbourhood.—A. HENDERSON.

Welbeck, Worksop.—Apricots are an average crop. Peaches and Nectarines under average, but the trees are very healthy. Of Pears we have very few indeed; and of Apples scarcely any. Plums are very fine. Morello Cherries a partial crop; and of other varieties we have very few. Strawberries are plentiful. Gooseberries, Raspberries, and Currants are under the average.—R. CARR.

Chilwell, Notts.—We have upwards of 90 acres of fruit orchards, mainly Apples; but we have also a good many Pears and a few Plums and Damascenes. This season is undoubtedly the worst as regards fruit culture which we have experienced for many years. Apples are a complete failure; during the whole time they were in bloom the blossom, which was exceedingly abundant and very fine, was subjected to a daily downpour of rain, which reduced the clusters of bloom to so many decaying masses like tufts of wet hay. The only exceptions to this state of affairs are the Russian or Duchess of Oldenburg and Walker's Summer Brooding, which are bearing fair crops. The former variety rarely if ever fails to bear, even when such sorts as Keswick, Domine, and the Barton Free Bearer succumb. I fear we have no prospect for next year, most of the trees being so covered with caterpillars that they have hardly an entire leaf on them, and present the appearance of having sniffered from a severe frost. Pears vary a good deal; some of the earlier and hardier varieties are bearing fair crops, whilst on the later sorts there are none. Those which show the best are Early Crawford, Hessele, Beurré d'Amanlis, and Grey Beurré. Plums are very scarce with the exception of Victorias, which are from one-third to half a crop. Damascenes are a good half crop. Small fruits, such as Gooseberries, Currants, and Raspberries, are very good; but the two former have been stripped of every vestige of foliage by the Gooseberry caterpillar. Of Peaches we have none, and but few Apricots. Wall Pears are fair crops in most situations. I suppose the day is not far distant when we shall see our walls devoted to good Pears instead of second-rate Peaches, which are so often a failure, and these latter will take their legitimate place in the orchard house, where one may always count on a crop and seldom if ever be disappointed.—ALFRED H. PEARSON.

Attingham, Shrewsbury.—Fruit of all descriptions is from three weeks to a month late. Apricots are a full crop, though small, and a good many are falling off now; the trees have lost several large branches, and some have died altogether. Peaches and Nectarines are an average crop; the trees suffered greatly from curl and blister in the spring, but they are growing freely now. Plums are a full crop (especially Damsons, Victoria, and Diamond), except Green Gages, which are very thin. Apples are about an average crop; of some kinds we have a heavy crop, while others are very thin; King of the Pippins, Winter Greening, Brabant Bellflower, Keswick Codlin, Yellow Ingestrie, Norfolk Beefing, Hawthornden, and two others of which I do not know the names, are bearing the best crops with us this year. Amongst Pears, Green Yair, Comte de Lamy, Althorp Crassane, Beurré Superfin, Hessele, and Glou Moreceau are the best bearers with us this year, though Glou Moreceau is very much spotted with black fungus. Gooseberries and Black Currants are a very small crop; the bloom was destroyed by the severe weather which occurred about the middle of April. Of Red and White Currants and Raspberries we have good crops. Strawberries have been plentiful, though great quantities have rotted without ripening through so little sunshine; consequently, they have been comparatively flavourless. The soil in this garden is loam resting on gravel.—G. PEARSON.

Bloxholm Hall, Sleaford.—Fruit crops in this locality are with few exceptions much under the average. Apples, Pears, Plums, and Cherries blossomed well and promised to be abundant, but with the exception of Keswick Codlin, Warner's King, Manks Codlin, Cellini, and Downton Pippin, which are bearing fair crops, all sorts are a failure. Pears on walls are a fair crop, but on pyramids and standards there are very few. Plums altogether are scarce; Cherries a failure. Apricots where protected a fair crop, but the loss of branches on young and old trees alike has been great, and in some cases the trees have been killed outright. Peaches are a fair crop where protected with Frigi Domo, but their leaves are much blistered. Strawberries have been an abundant crop, but many rotted through excessive wet. Raspberries are abundant. Gooseberries a fair crop; Black, Red, and White Currants rather under average, but fair crops. Nuts are abundant, but I do not think they will ripen unless we have better weather.—D. LUMSDEN.

Osmaston Manor, Derby.—Apples, Pears, Apricots, Plums, Damsons, and Cherries are but medium crops hereabouts; Strawberries, Raspberries, Gooseberries, and Red and Black Currants heavy crops; Peaches, Nectarines, and Figs are only grown indoors. Of Walnuts we have none, and Filberts are not grown in this district. The soil here is almost all gravel, and to grow fruit well clay should be used to co-operate with it. The following are the best fruits for this district: Pears—Marie Louise, Louise Bonne of Jersey, Williams's Bon Chrétien, Gansel's Bergamot, Comte de Lamy, Beurré d'Aremberg, Easter Beurré, Winter Nelis, Glou Moreceau, Passe Colmar, and Jargonelle. Apples (dessert)—Court Pendu Plat, Cox's Orange Pippin, Gravenstein, Ribston Pippin, Sturmer Pippin, Margaret, Fearn's Pippin, and others; kitchen—Blenheim Pippin, Cox's Pomona, Hawthornden (both old and new), Keswick

Codlin, Manks Codlin, Northern Greening, Dumelow's Seedling, Warner's King, Waltham Abbey, Lord Suffield, Minchall Crab, and others. Cherries—Elton, May Duke, Black Tartarian, Black Eagle, Bigarrean Napoleon, and others. Plums—Blue Gage, Green Gage, Coc's Golden Drop, Dove Bank, Kirke's, Jefferson's, Victoria, and Washington. Black Currants—Naples, Warner's Grape and Victoria. Gooseberries—Warrington and Crown Bob.—J. BOOTH.

SOUTH-WESTERN DIVISION.

Badminton, Chippenham.—Fruit crops in this neighbourhood are, generally speaking, very unsatisfactory, the quantity being light and the quality poor. With us Apricots are quite a failure, and the trees seem to lose a good many branches. Peaches and Nectarines out-of-doors, except in very sheltered spots, have but little fruit on them; Rivers's Orange Nectarine is an exception, being first-rate both in fruit and foliage. Apples are scarce and the trees very much blighted. Pears, on the other hand, are a fair crop and very healthy; likewise Plums. Small fruits have been abundant and good, Currants and Gooseberries particularly so. The continued wet spoiled many Strawberries, but the crop was good. The Gooseberry caterpillar has made sad havoc in many gardens around this part, many of the trees being entirely stripped of foliage.—WILLIAM NASH.

Moreton, Dorchester.—Fruit crops in this district are on the whole tolerably good, but much in want of warm, sunny weather. We are fully three weeks later than usual. Peaches on walls, where they received some slight protection until June, are bearing fair crops, but unless we get some warm, sunny weather they will be very late in ripening and will be deficient in flavour. In orchard-houses crops are good and the fruit fine. Plums are a fair crop, best where the situation is high and dry. Pears are good on walls, but very light on espaliers and pyramids. Figs good, Apples are very light, and what fruits we have are very small; all trees blossomed well but did not set, owing to the low temperature and moisture-saturated atmosphere at the time of flowering. Our best sorts are Blenheim Pippin, Hawthornden, Tom Put, Keswick Codlin, and Starmer Pippin. Strawberries have been a good crop, and the fruit fine, but lacking flavour, and many rotted. Raspberries good and fine. Currants of all kinds good. Gooseberries generally thin, owing to bullfinches destroying the buds in spring. Since the 1st of June we have had 11'68 in. of rain.—D. UPHILL.

Sherborne Castle.—Fruit crops in this neighbourhood are in a very unsatisfactory condition though all kinds bloomed and set well. Apples are thin and much disfigured, and the trees are in a very unhealthy state. Pears are an average crop. Apricots are thin and very late, none yet ripe. Morello Cherries are about half a crop, but very good. Peaches and Nectarines on walls are about a third of a crop; both fruit and wood are very backward, and I fear neither will ripen this season. Plums are a complete failure. Of small fruits, Gooseberries were all cut off by frost; Currants very plentiful but much blighted; Strawberries and Raspberries very plentiful, but much injured by wet; Nuts are plentiful in some places.—W. G. PRAGNELL.

Carclew, Ferran-ar-Worthal, Cornwall.—Plums are about half a crop, but I doubt if many will ripen. Early Cherries are a fair crop, Morellos third of crop. Apples are a fair crop, but the fruit seems likely to be small. Pears with us are better than usual. Of Peaches and Nectarines we have fruit enough where the trees are healthy, but as a rule the latter are much blighted. Strawberries have been an average crop, but indifferent in flavour. Gooseberries heavy and fruit fine. Currants, Red, White, and Black, also good. Raspberries good. The Apple crop in this neighbourhood is a very short one, and the trees in exposed situations are much blasted by a south-westerly gale which we had about three weeks ago. Small fruits have been generally good, but all and everything very late and out of season.—GEO. PALMER.

Powderham Castle, Exeter.—The Apricot crop here is rather above the average, but the trees have died back very much, and some are quite gone. Plums on walls are very thin, and we have none on standards. Early Cherries were a full crop, but they were much damaged by the incessant rains; Morellos are under the average, many having fallen off during the stoning period; Kentish thin. Peaches and Nectarines are average crops; the foliage suffered much from cold during the spring; I have seen many trees in this neighbourhood a total wreck from cold and aphides this season. Of Apples most varieties are very thin, but of King of the Pippins and Cellini we have abundance. Pears are under the average, but we have a good crop of Williams's Bon Chrétien both on wall and bush trees. Currants, Red and White excellent; Black suffered much from blight. Gooseberries under the average, the buds having been destroyed by small birds in winter. Raspberries very good. Strawberries abundant and very fine, both early and late; Marquis of

Brittany, Lucas, Alicé Maude, and Elton Pine very good; the latter, planted on borders with different aspects, has produced a good late supply; James Veitch was very fine, but inferior in quality. Filberts and Nuts abundant; Walnuts under the average. Soil a light sandy loam.—D. C. POWELL.

Killerton, Exeter.—Apricots here are under the average; Plums on walls over the average, scarce on pyramids. Cherries under the average, and trees blighted. Peaches and Nectarines an average crop on young trees, old trees much injured. Apples very scarce generally. Pears an average crop on walls, scarce on pyramids. Small fruits such as Raspberries very fine and plentiful. Red and White Currants and Gooseberries good crop. Black Currants much blighted and scarce. Strawberries an average crop. Nuts plentiful; Walnuts scarce. All fruits very backward; Peaches and Nectarines not begun to swell after stoning.—JNO. GARLAND.

Clevelands, Lyme Regis.—The year 1879 is one of the most fickle and unprecedented on record as far as fruit culture is concerned. The extremely rainy and foggy weather experienced for the last six or eight months has necessarily told seriously on fruit prospects. In the early part of the season all fruit trees presented unusually promising prospects. The trees being well set with blossom buds, and the season at least three weeks later than usual, hopes were entertained of a fine fruit crop. But alas! when the Apples, Pears, and Plums were in bloom, we were enveloped in fog and rain, which caused most of the blossoms to rot and decay on the trees, and the few that did set mostly dropped off afterwards, so that the crop of Apples, Pears, and Plums is much below the average in most places. Peach and Nectarine trees have also suffered, the foliage being injured, and the crop of fruits poor and deficient. Indoors they are all that could be desired, thus showing the advantage of growing such fruits under glass. Bush fruit, except Currants, are plentiful, but small, and suffering from extreme moisture. Strawberries have been plentiful, but, like most other fruits, are deficient in flavour. Walnuts are scarce. Hedge Nuts plentiful.—H. MONRO.

NORTH-WESTERN DIVISION.

Abney Hall, Cheadle.—Small fruits, such as Strawberries, Raspberries, and Red and Black Currants, have been very good crops. Strawberries during the wet time when they were fit to gather were unsatisfactory, but embracing favourable opportunities we have got a full supply; Lucas and President are the two best sorts we have. Of Black Currants I never had a better crop, and the same may be said of Red Currants. Of Raspberries we shall also have plenty, and they are very good in quality. Gooseberries, just ripening, are good, both as regards crop and quality. Pears with me are better than Apples, the latter being very thin indeed. A neighbour, who is a large grower, tells me that with him Apples are better than Pears; the Lord Grosvenor Apple is carrying fine crops. Victoria Plums and Damsons are full crops, but this season I doubt if they will ripen satisfactorily. Morello Cherries, too, are very late; we have had them ripe before this in former years, and, now they are just changing colour.—ROBERT MACKILLAR.

Waterdale, St. Helen's.—Fruit crops around here generally are good, but three weeks late. Peaches and Nectarines on walls, that have received ordinary protection, are good, and also Apricots. Pears are a good crop, except some of the tender sorts. Choice sorts of Apples are very thin, but the hardier varieties, such as Greenings, Lord Suffield, Hawthornden, Manks and Keswick Codlin, are well loaded. Morello Cherries are good, but other sorts thin. Damsons I never saw better; other Plums an average crop. Gooseberries and Red Currants are fair crops. Black Currants promised to be good, but dwindled away. Raspberries are an excellent crop. Owing to the cold, damp season, Strawberries neither set nor ripened well; Sir Joseph Paxton, however, seemed to defy both wet and cold; he has far outtrivalled all the others, both as regards quality and quantity; President comes in second best.—JAMES SMITH.

Haigh Hall, Wigan.—Fruit crops in this locality are below the average. Stone fruits are never good here. The gardens are greatly exposed to the east wind, and the soil is a poor, hungry, adhesive loam which seems to retain too much moisture. Fruit trees grow well but seldom ripen their wood. The brilliant sunshine of last autumn, however, ripened the wood fairly well. All fruit trees blossomed abundantly and strongly this spring, and, being late, expectations of a good fruit crop were entertained; but the continuous low temperature, absence of sunshine, and the very heavy rainfall during the months of May, June, and July, destroyed the bright expectations of spring. Insect pests have been more numerous than usual; evidently they found a safe hiding place during the late severe winter. Apples are a very poor crop; Cellini, Lord Suffield, Keswick Codlin, Yorkshire Greening, and Small's Admirable are the best. Pears on south walls are above an average;

Easter Beurré, Beurré Diel, Marie Louise, and Glou Moreau are the best. Cherries are a failure except Morellos, which are an average crop. Of Plums we have scarcely any. Gooseberries are plentiful but small, and suffering from caterpillar, many of the bushes being quite leafless. Strawberries are plentiful but small and deficient in flavour; Duc de Malakof, Black Prince, Vicomtesse Héricart de Thury, and Eclipse are the best. Black Currants are scarce. Red Currants and Raspberries very good.—ANDREW JAMIESON.

EASTERN DIVISION.

Gunton Park, Norwich.—Apricots here are thin except where planted in very sheltered situations. Amongst Pears we have good crops of Victoria, Rivers's Early Prolific, Angelina Burdett, Pond's Seedling, Prince Englebert, and Kirke's; other varieties are very thin. Of Bigarreau Napoleon and Black Hawk Cherries we have good crops; Morellos cracked and are useless. Peaches and Nectarines are bad, and the trees are killed, or nearly so, in many places. Those under Frigi Domo set good crops, but were afterwards ruined by east winds, which commenced in the latter part of April and continued till the middle of May; every leaf blistered and turned black. Of some kinds of Apples we have heavy crops, but many sorts are fruitless. Amongst Pears we have good crops of Williams's Bon Chrétien, Winter Nelis, Josephine de Malines, Count de Lamy, Louise Bonne, Beurré Diel, Beurré Bosc, Beurré Bachelier, Glou Moreau, Passe Colmar, and Bergamot d'Esperen, but Marie Louise and other good sorts are without a single fruit. Raspberries are a fine crop. Gooseberries an average crop. Red and Black Currants abundant. Strawberries have been unusually fine, the crop heavy, and the fruit very large. On our soil, a sandy loam, the following varieties succeed best, viz., Sir Harry, Sir Joseph Paxton, Sir Charles Napier, Vicomtesse Héricart de Thury, President, Amateur, and President de la Cour; the last distinct and good. Crimson Queen, Lucas, Dr. Hogg, British Queen, and James Veitch do not crop freely on this soil. Filberts are a heavy crop. Walnuts thin and very late. 1879 will be remembered as a year of slugs, as well as of absence of sunshine, and for rain and low temperature. The slugs cleared off first sowings of Beet, French Beans, Lettuces, Cauliflowers, Brussels Sprouts, &c., completely; after using as preventives lime, soot, wood ashes, &c., all to no purpose, we were obliged to catch and kill. Our plan was to lay down Cabbage leaves over night, and send two men the first thing in the morning to pick up the slugs. One man picked up 1060 in one hour and a half. We followed up the above system for upwards of a month, all over the garden, keeping the Strawberry beds free from them in the same way; so we had comparatively no slug-eaten Strawberries, which is saying a great deal such a season as this.—W. ALLAN.

Cossey Park, Norwich.—Apricots here are a good crop. Plums an average one. Cherries good. Peaches and Nectarines thin. Apples and Pears average crops. Small fruits excellent. Nuts an average crop. Raspberries very good.—E. BURBERY.

Wolverstone Park, Ipswich.—With the exception of Strawberries and bush fruits the present season is the worst as regards fruit crops that I ever remember, for not only are the more tender kinds almost a total failure, but even Apples and Pears are unable to make any headway. The latter although plentiful enough are no larger than they generally are at the end of June, and therefore, should they even swell rapidly now, they are sure to be hard-grained and poor in quality through the severe check which they have already undergone, as no fruit suffers so quickly in this way as that of the Pear. Apples are very variable, some sorts carrying good crops, and others none at all. The best with us are Cox's Orange Pippin, Cox's Pomona, and Keswick Codlin. Cherries, although they appeared to set well, mostly dropped during the period of stoning, and the few that remained have split and rotted, owing to the excessive rainfall; but Morellos being later have escaped, and what few there are promise to be large and fine. Plums on walls are very thin indeed, but on standards there is a full crop, the best being the Victoria and Prince Englebert, the former of which is a very sure cropper. Damsons are not much grown about here, but Bullace trees are laden, so much so that their branches are quite bent down. Figs promised to be good, but the cold and wet have caused nearly all to fall; and as to Apricots, the trees in most places are mere wrecks without hope of recovery. Ours, although fruitless, are not so bad, and, if we get a fine autumn, will again cover most of the gaps. Peaches and Nectarines have improved greatly of late, but the fruit is in a very stunted condition, and covered with gum spots. Strawberries have rotted a good deal, and have lacked flavour, but Raspberries have been good and in the greatest abundance, as are also Gooseberries and Currants. The soil here is light, resting on sand and gravel, and in ordinary seasons suits all kinds of fruits, except Apples and Pears on the Quince, for which it is too dry.—J. SHEPPARD.

Hardwicke House, Bury St. Edmunds.—In general terms fruit crops are a failure, though never did they promise to be better than they did early in spring. The trees were healthy beyond the average of seasons, the bloom abundant and strong, and the season abnormally late. The latter especially almost ensured a crop of the later flowering fruits, such as Apples, and the hopes of growers ran high; but most of these have been dashed to the ground with the showers of embryo fruits until hardly any are left. The Apricots were the first to suffer, and they have suffered most. Not only are the majority of the trees bare of fruit, but the trees themselves have perished in whole or in part. Never within the range of an experience of over thirty years have I seen such cruel slaughter among the Apricot trees. The walls are terribly disfigured or wholly bare. Peaches set well, and soon after suffered semi-devouring from aphides, that came upon them like locusts, and devoured them almost as rapidly and completely. Still we have a fair sprinkling of fruit left, which may ripen if we are favoured with some forcing autumnal weather before winter. The wood is also growing fast where the aphides were summarily dealt with and destroyed at once. Plums are scarce on the whole, though here and there our standards are well laden, whilst almost everywhere the walls are bare or nearly so. We have had a good crop of early Cherries, most of which, however, were split and ruined by the rain; while Morellos are thin. Pears are specially capricious, and this unevenness of crop seems to depend far more on locality than variety. In some places and positions there is a good crop of most sorts; in others, few or none. Pears, however, will, on the whole, be the best crop of the season, a fact which it is not difficult to explain, as Apples, which flowered considerably later, have dropped and dropped until there are hardly any left. The trees have also been severely attacked with a sort of mildew or brown rust, which has given them a most stunted, unhealthy appearance. On no variety here, nor any form of tree, have we a full crop of Apples this season. One of the most curious facts in relation to this is that the Apples have not been wrecked by the frost but rather washed off by the rain; but of course this could hardly have been the case had the fruit been properly set. Walnuts are scarce, and wood Nuts and Filberts plentiful. Our bush fruits have also been a capital crop of good quality, and Strawberries a heavy crop, but the flavour was washed out by the rain and a great portion of the crop rotted. In low-lying gardens much of the crop was flooded, coated over with mud, silted up with sand, and utterly ruined—altogether the worst fruit crop of the entire series of bad years.—D. T. FISHER.

Audley End, Saffron Walden.—The fruit crop in this neighbourhood is far below the average. Apricots, Peaches, and Nectarines are almost a total failure, owing, doubtless, to the wet, cold spring and summer which we have had; the early leaves of the Peaches and Nectarines became blistered and fell off, but the trees are now improving. Apples are a light crop. Pears about an average crop; fruit good. Plums and Figs light. Strawberries and small fruits are average crops. Nuts over the average.—W. HARRISON.

Shrubland Park.—This is the most disappointing season in my recollection as far as fruit culture is concerned. Apricots and Peaches on walls, though well protected, are a total failure, and the trees are rendered useless for at least a couple of years. Apples are also very scarce and the trees much blighted. Pears on walls are an average crop, but the fruit of most kinds is small; on standards they are very thin, many being without fruit; Williams's Bon Chrétien, Louise Bonne of Jersey, and Beurré d'Amanlis give the best results. Cherries don't succeed out-of-doors here. Plums on walls are a tolerable crop, and Damsons are good. Filberts are plentiful, but Walnuts are scarce. Of small fruits we have good crops. The soil in this neighbourhood is variable but the chalk formation prevails.—THOS. BLAIR.

YORKSHIRE.

Grimston Park, Tadcaster.—Apricots are an average crop, but very late; the trees have suffered much from large branches dying off suddenly; our standard variety is Moor Park. Apples of the commoner sorts were an average up to about ten days ago; since then quantities have dropped off; Cockpit, Warner's King, Yellow Ingestrie, Lord Suffield, Cox's Orange Pippin, and Beauty of Kent are our freest bearing sorts. Cherries are not quite an average crop with us, but in some places in the neighbourhood there are good crops on standards, especially where sheltered from north and east winds. May Duke is the best as a standard, though we ourselves usually get our finest Morellos from some large pyramidal shaped trees in the kitchen garden. Peaches and Nectarines are very thin, and, unless we get some good weather shortly, will, I am afraid, never ripen; Royal George, Early York, and Bellegarde are our best Peaches, and Violette Hative and Balgowan our best Nectarines. Plums are partial here; the only variety that has a good crop is Victoria, but I hear

of good crops of some of the common sorts, on standards. A few miles from here there is a sprinkling of Winesours, which are largely grown not far from this place. Pears are not an average crop, and are like everything else, very late. Jargonelle, Louise Bonne of Jersey, Doyenné d'Été, Citron des Carmes, Josephine de Malines, Brown Beurré, and Autumn Bergamot are producing good crops. Currants are excellent, also Gooseberries and Raspberries. Strawberries are the heaviest crop we ever had, but owing to the wet weather quantities have rotted before they were fully ripe. Héricart de Thury, Keen's Seedling, President, and James Veitch are our standard varieties. Amongst some newer sorts on trial we find Helena Gloëde to be a capital variety for late work; we are still picking fine fruit from it, the produce of plants planted out of 4-in. pots last August. Our soil here is a stiff loam resting on magnesian limestone, and suits most fruit trees with the exception of the finer kinds of Pears, which are apt to be gritty at the core.—H. J. CLAYTON.

Ribston Hall, Wetherby.—Apricots hereabouts are an average crop. Plums heavy on bushes, but thin on the walls. Cherries very thin. Peaches and Nectarines thin. Apples under an average. Pears very thin. Small fruits good. Strawberries were excellent, but suffered very much from wet and slugs. Medlars are very good. Fruit crops are late, and unless we have some unusually fine weather this autumn, Apples, Pears, &c., will be small and poor.—T. JONES.

Thorpe Perrow, Bedale.—Here the fruit crop is generally good, but so very late that it is doubtful whether stone fruits will ever become ripe. Apricots show no signs of ripening as yet. The Apple crop is good. Nectarines and Peaches are good. Plums bad. Of Cherries we have a moderate crop. Pears good. Bush fruits of all kinds abundant and particularly fine, as regards size, but deficient in flavour. Strawberries plentiful and very large, but wanting in quality. Nuts everywhere in this district abundant, and the same may be said of Hedge Nuts.—W. CULVERWELL.

NORTHERN DIVISION.

Shawdon, near Alnwick.—Small fruits are very abundant in most gardens in this neighbourhood, and if the weather clears up they may yet be gathered in good condition. Apples vary; they are generally abundant upon old trees, but thin upon dwarf standards. They came into blossom a month later than usual, and I have seen Apples further advanced in the middle of June than they are now. Many varieties will never come to perfection, even under the most favourable weather; the same may be said of wall fruits. I am now gathering May Duke Cherries from the same trees from which I usually gathered fruit in the early part of June. Peaches, Apricots, and Pears are fair average crops, but owing to incessant rains rust is affecting Pears very much in some gardens. Altogether the prospect of a fruit crop in this district is very unsatisfactory. Strawberries, in many places, have been lost. Of all the varieties that I have tried in this place I find President and Garibaldi the most serviceable; they stand wet, and ripen under most unfavourable weather, and they are suitable either for dessert or for preserving. President is well suited for pot culture. Some fifteen years ago I saw it exhibited at the Leeds Horticultural Show in pots in such perfection as to mark it at once to be a first-class hardy Strawberry. Until the owners of gardens in the north of England take the question of glass protection for fruit into serious consideration they cannot expect to see good Peaches and Pears upon their dessert table. It is not protection alone to spring blossoms that we want; we must assist Nature; we cannot manufacture sunshine nor ward off pouring rains; therefore glass must be more extensively used in this part of the country, if we are to be visited every now and then by a succession of such years as that which we are passing through. Of all the early Pears that come to perfection in this district Williams's Bon Chrétien is decidedly the best. The trees grow clean and healthy, the fruit large and fine, ripening in ordinary years about the first week in September. This Pear deserves to be more extensively grown in this district. Should it come to perfection this season it will be a boon indeed, for the year 1879 will long be remembered in the annals of gardening as one of the worst that we have experienced during the present century.—J. THOMSON.

Alnwick Castle.—We cannot complain that our trees in this district are without fruit; but the question is, will it ever ripen? Apricots are a good crop, and the trees are clean and healthy. Of Apples, some sorts are good, of others we have next to none; and the same may be said of Plums. Pears, with few exceptions, are a good crop. Nearly all sorts of Pears do well here. Cherries on the whole are below the average. Of Peaches, Prince of Wales and Royal George are the best. Nectarines, consisting of Pine-apple, Pit-maston Orange, and Hardwicke Seedling, are an average crop. Straw-

berries and all small fruits have been abundant. We are 180 ft. above the sea-level, and our soil is light and dry. The only protection we use in spring is two or three ply of herring-net, and if properly fixed I find it to be the best protection I have ever tried.—ALEX. INGRAM.

Seaham Hall, Durham.—Apples on some trees are a fine crop, while on others there are none at all; the best bearing sorts are the Codlin, Hawthornden, Rymer, Blenheim Orange, Golden Pippin, and Ribston. This is not a good locality for Pears except on walls; only the commoner sorts come to perfection; the Seckel, Louise Bonne of Jersey, and Jargonelle in some summers do very well, but not in seasons like the present. Of Plums, only the Victoria will fruit in perfection, although more inland from the coast they bear fairly well. Apricots succeed on walls, but no great quantity of them are grown hereabouts. Peaches and Nectarines are not as a rule grown out-of-doors. Of Strawberries, almost all sorts do well except the British Queen. Raspberries are a sure crop, and Gooseberries are the same if not pruned. Currants also bear well. Our soil consists of various kinds, mostly of a stiff character on the limestone. The land near the sea is light and good for Potatoes and all root crops; we are more troubled by the late east winds in May than by frosts.—R. DRAPER.

Raby Castle, Darlington.—Fruit prospects as far as the gardens here are concerned are without exception all that could be desired. The season is at least three weeks late, but bush fruits of all kinds are very fine and clean. Strawberries are excellent. Cherries abundant. Plums and Apricots are also good. Peaches and Nectarines are not grown here on open walls. The fruits most likely to suffer from the lateness of the season are Pears and Apples. The former are very clean and healthy, but Apples are a good deal blighted, and the fruit has dropped off a good deal; but generally speaking there is plenty left where quality is preferred to quantity, and I have no doubt if we get a hot September both Pears and Apples will finish up well. We do not shelter our trees in any way, but usually we have to use every possible means to protect fruits of all kinds from the ravages of birds, blackbirds especially; but this year we very rarely see one, and I have not yet found it necessary to spread a single net. The late severe winter I expect was beyond their endurance. We have a good number of thrushes, which are the more useful of the two, though not so melodious.—R. WESTCOTT.

Lambton Castle, Durham.—Fruit crops hereabouts suffered severely from the hard winter and late spring frosts. Apples on some trees are a good crop, especially on trees lifted and replanted in 1877; others are somewhat thin. The following sorts are the best, viz., King of the Pippins, King Apple, Large Cockpit, Oslin, Ecklinville, Braddick's Nonpareil, Lord Suffield, Manks Codlin, Sturmer, Cockle Pippin Claygate Pearmain; they are fully a month behind, and it is questionable if they will ripen. Pears are best represented by the following sorts, viz., Jargonelle, Easter Beurré, Hacon's Incomparable, Hesse, Green Yair, Louise Bonne of Jersey, and Althorp Crassane. Apricots are a complete failure, and the trees are half killed. Peaches and Nectarines are a fairly good crop. Cherries an average crop, and fine in quality; Morellos especially are fine on pyramids, far outstripping those on walls. Plums are very thin, except Victorias, which are good. Gooseberries are abundant and fine, and the same may be said of Red and Black Currants. Strawberries are particularly plentiful; but, through the incessant rains, many have been spoiled. Small fruits have never been equalled in my experience in the county of Durham. Raspberries are also well represented. The severity of the winter has made terrible havoc amongst our shrubs, upwards of 320 large cartloads having been destroyed. Amongst them were upwards of 100 cartloads of the common Yew, which was killed outright. Our soil is a stiff, holding clay. Trees and shrubs grow late in the autumn, and are often imperfectly ripened. Lying as we do on the level of the river, thick fogs and hoar frosts are prevalent and injurious to our vegetation.—J. HUNTER.

WALES.

Cardiff Castle.—Apples here are under an average crop; the fruit is small and the trees much blighted. The varieties bearing best this year are Lord Suffield, Hawthornden, Cellini, and Ecklinville Seedling. Pears are very scarce, both on pyramids and walls; the trees are healthy and clean, and now making a superabundance of wood. Beurré Diel, Beurré Clairgean, and Early Windsor are producing the best crops of medium-sized fruit. Apricots are an average crop, and the trees are healthy and clean. Plums are very scarce, with the exception of Victoria, which is always a pretty sure-bearing kind in most districts. Peaches and Nectarines are an average crop; the trees were much blighted in the early part of the season. Small fruits are plentiful, especially Strawberries, but they are much injured by heavy rains.—A. PETTIGREW.

Bodorgan, Llangefni.—Fruit crops with us, and as far as my information goes, are below an average, with trifling exceptions, both in quantity and quality. The season is about three weeks later than usual, and till within the last week or ten days the weather throughout the summer has been cold and wet with but little sunshine. Apples are mostly a light crop and small; in fact, unless we have a few weeks of bright hot weather, the later kinds will be of little value; and the same with Pears, which are under an average. Though late, there was a fine bloom on Apples and Pears, and, in fact, on all hardy fruits. Strawberries were a most abundant crop, the bulk of which perished from the continued wet. Other small fruits, such as Currants, Raspberries, &c., have been pretty good, though not so abundant as usual. The later kinds of Apples, requiring a warm soil and climate, such as Newtown Pippin, Court Pendu Plat, and Nonpareil, rarely do much good in this district except the season be very hot. The same with late Pears; Easter Beurré, Beurré Rance, &c., are failures. Peaches, Nectarines, and Apricots do not succeed except under glass. Morello Cherries do remarkably well, but Plums are uncertain. The climate of this part of Anglesey though mild is too much under the influence of salt winds from the sea to render hardy fruit growing on the whole successful or satisfactory. The trees are very liable to canker and get Moss-covered.—J. ELLAM.

Margam Park, Glamorganshire.—Taken as a whole this is a bad fruit year in this neighbourhood. Apples, consisting of Keswick Codlin, Manks Codlin, Hawthornden, King of the Pippins, and one or two others, are bearing fairly good crops, but as a rule they are producing only a quarter of a crop. Pears on standards are bearing but few fruit, but on walls they are plentiful. Plums are about a quarter of a crop; the Victoria is bearing fewer fruit than usual, but Damsons are bearing more than they have done for many years. Peaches with us, on open walls, are about half a crop. Apricots thin. All the above fruits are small this season. Of Cherries on standard trees we have none; sweet ones against walls are scarce, Morellos abundant. Strawberries have been an enormous crop, and the same may be said of all kinds of Currants, Raspberries, and Gooseberries. None of our fruit trees were protected in spring.—J. MUIR.

Castle Malgwyn, Cardigan.—Fruit crops hereabouts are all wonderfully late and delicate in flavour. Plums are plentiful; Green Gages, Victorias, Orleans, Jefferson, Coe's Golden Drop, and Magnum Bonum succeed well here. Of Cherries we have very few. Peaches are a fair average crop, and though the leaves were blistered very much in the spring, the trees are now recovering. Apples are few and small; King of the Pippins, Lord Suffield, and Hawthornden are bearing the best crops; most sorts of Apples succeed well here. Pears are under the average; they do not succeed well in this district as pyramids or espaliers; those that generally yield the best crops on walls are Jargonelle, Williams's Bon Chrétien, Summer Begamot, Autumn Bergamot, Glou Morceau, Comte de Lamy, and a few others. Of Currants we have very few. Raspberries and Gooseberries are average crops. Strawberries have been plentiful, especially Newton Seedling, from which I am still gathering. Nuts are abundant, but Filberts are late. I never remember seeing more Nuts on hedgerows than we have this year. The soil hereabouts is chiefly heavy, but with care excellent crops of most things may be grown on it.—HENRY HOWARD.

SCOTLAND.

Drumlanrig, Dumfriesshire.—All fruit trees and bushes could scarcely have given greater promise than they did in spring of bearing abundant crops. They were literally smothered with fine healthy blossom buds, no doubt owing to the fine warm autumn of last year; but the extraordinary cold, wet, and want of sunshine which have characterised this season all along have very much altered matters. Apples are an average crop, but so very late that, unless the next two months be exceptionally warm, they will scarcely be worth gathering. The same remarks apply to Pears, which are a small crop. Plums on walls are a poor crop, with the exception of the never-failing Victoria. Strawberries have been very abundant, but flavourless. Black and Red Currants, as well as Raspberries and Gooseberries, are abundant, but deficient in flavour. The lowness of the temperature and constant rains have been most remarkable. The highest temperature registered in July was 71°, the mean of the highest readings being only a fraction over 60°, and June was still colder. On August 10 the temperature fell to 34° in a sparred box 4 ft. from the Grass, and very frequently it has ranged from 36° to 40° during the last three months.—D. THOMSON.

Tynningham, East Lothian.—Fruits which did not set well here were Apples and Strawberries. The former either rotted in the blossom or their stalks were eaten off by a maggot. The Straw-

berries were cut up by a fierce storm of wind, which scathed the later flowers as if by fire. Notwithstanding this, however, we have had good crops. President suffered most. Vicomtesse Héricart de Thury, Sir J. Paxton, and John Powell are amongst our best sorts. Lucas, Helena Glòde, and Loxford Hall Seedling are good croppers. President de la Cour, I fancy, would be worth growing on dry soils. Pioneer apparently requires a warmer climate than ours. The Apples which have set good crops are—Lord Suffield, not so good as it generally is; Keswick Codlin, the best crop of the year; Hawthornden, Stirling Castle, Cox's Pomona, and King of Pippins. Dessert sorts are almost a failure. Of Pears, Winter Nelis carries the largest crop; Bon Chrétien, Marie Louise, Van Mons Leon le Clerc, Napoleon, Easter Beurré, and Glou Morceau are also producing good crops. Apricots are good. All sorts of Plums are next to a failure. It is doubtful whether any of these Apples, Pears, Apricots, or Plums will ever become fully grown. Everything depends on the weather. Cherries have all set a large crop, but so far they have cracked and rotted on the trees. Of all kinds of bush fruits there are grand crops. Gooseberries are bending the branches to the ground by their weight. Raspberries I have never seen better. Currants also are extra crops, but they are suffering through the wet. Our trees have not been protected this year at all. All kinds of usually protected trees were so late in opening their flowers that we dispensed with protection. Herring-nets are the only kind of protection used here. I have much more faith in getting the young wood thoroughly well ripened in the summer and autumn as a means of securing a crop of fruit than in trying to save imperfectly developed flowers in the spring.—R. P. BROTHERSTON.

Culzean Castle, Ayrshire.—The fruit crop in this neighbourhood is in general very varied. In some gardens Apples and Pears are quite a failure, while in others they are an average crop. Gooseberries and Currants are very abundant, the bushes quite weighed to the ground with the fruit. Strawberries have been very poor, the half of the fruit not coming to maturity. Plums are an average crop. Cherries, except Morellos, have been very poor here, but in some places they have been good crops. The following fruit trees are bearing crops here this year:—Plums—Victoria, Kirke's, Goliath, and Jefferson; Pears—Williams's Bon Chrétien; Apples—Lord Suffield, Paradise Pippin, Cellini, and Ecklinville Seedling. The garden here is well sheltered from east and north winds. The soil is heavy on clay.—DAVID MURRAY.

Gordon Castle, Fochabers, Banffshire.—Strawberries hereabouts and all bush fruits are abundant. Apples are also good. Pears a fair crop. Plums good, some sorts over the average. Peaches on some trees good, on others bad; Apricots set well, but both trees and fruit are badly blighted through want of sun-heat and a continuation of cold east winds.—JOHN WEBSTER.

Bothwell Castle, near Paisley.—As a whole, the fruit crop in Lanarkshire is decidedly below an average. Small fruits with us are very abundant but very late, Gooseberries being still unripe; they are grown largely in this neighbourhood for the Glasgow market, and generally sold by auction; this year the prices obtained are very low, but I think that must be owing to the lateness of the crop, and general depression in trade, and not to any deficiency as to quantity. The Apple and Pear crops are very deficient; the Stirling Castle and Lord Suffield Apples give very satisfactory results here, and I believe I state very nearly the truth when I say that in the Glasgow nurseries more of these two sorts are sold than of all other kinds put together. The Peach crops are abundant but very late, and unless the favourable weather that we have enjoyed for the last two or three days continues for a few weeks they are not likely to ripen satisfactorily; the sorts which I grow on the open walls are Acton Scott, Royal George, and Red Magdalene; when in flower they are protected from frost at night by scrim cloth. The subsoil of this district is generally clay. Strawberries on stiff soils have not done well this year; the Grove End Scarlet is an exception, and we still consider it the best for preserving.—ANDREW TURNBULL.

Blythswood, Renfrewshire.—Fruit crops in this district are not at all good. Apricots, Peaches, and Nectarines, protected in spring with spruce branches and on flued walls, have failed to carry even an average crop. Apples are also thin, and the fruit will be small in size. Even Lord Suffield and Stirling Castle are not so good as usual this season. Pears are an average crop. Cherries fairly good; Morellos have set well. Plums not an average crop. Strawberries were abundant, and would have been fine had the weather proved favourable. Garibaldi and Reeve's Eclipse have withstood the wet weather best. Of Raspberries we have very fine crops. Gooseberries and all the varieties of Currants are plentiful, and fine in quality.—J. METHREN.

Glamis Castle, Forfarshire.—Fruit crops in this quarter are scarcely up to the average, with the exception of small fruits, which are very abundant. Gooseberries, Raspberries, and Currants

are very abundant and good in quality. Strawberries here bloomed and set well, but owing to the cold wet season not more than half of them swelled; our standard varieties are Eclipse, Elton Pine, Keen's Seedling, Vicomtesse Héricart de Thury, and Wonderful. Apples and Pears made a fine show in spring, and their blossoms were strong, healthy, and late, escaping the late spring frosts, but like the Strawberry crop more than two-thirds of the crop have dropped after being well set. Among Apples, Codlins, Pippins, Ecklinville Seedling and similar kinds do well in good seasons. Amongst Pears Bergamots, Beurrés, Williams's Bon Chrétien, Jargonelle, Louise Bonne of Jersey, Marie Louise, Passe Colmar, Thompson's, and Vicar of Winkfield do best. Plums are quite an average crop, though we had to thin Victorias and Goliaths. It is seldom the Plum crop fails here. Our favourites are Coe's Golden Drop, Goliath, Green Gage, Jefferson, Kirke's Magnum Bonum, Orleans, Princee of Wales, and Victoria. Apricots are an average crop; Brussels, Moor Park, and Shipley's are principally what we grow. Our soil is chiefly a good light loam.—G. JOHNSTON.

Dupplin Castle, Perth.—Apricots are a good crop, but late. Plums scarce, and Apples and Pears are also thin. With so much rain and little sunshine Apples did not set well, and those that did are swelling very irregularly. Fruit trees in general are healthy and free from vermin. With the exception of Cherries, which are badly infested with black fly, small fruits are average crops, but Strawberries have been much spoiled through the wet.—J. BROWNING.

Ardross Castle, Ross-shire.—Small fruits hereabouts are good, except Strawberries, which are not nearly so good as they usually are. Apples are an average crop, but so late as to preclude the hope of their being of good size or quality. Pears are a failure. Plums below an average.—R. MASSIE.

Cawdor Castle, Nairn.—Apricots covered and Peaches uncovered had to be thinned to the extent of two-thirds or so, but they are so very late that it is questionable if they will ripen at all. Strawberries are good; Garibaldi, President, and Elton are the sorts grown. Gooseberries are above the average as regards quantity, but none are yet ripe. Raspberries are abundant and beginning to colour. Currants are plentiful but late and small. Apples are abundant on some trees, on others scarcely any; Lord Suffield, Stirling Castle, Oslin, and some others are full crops, but small. Cherries and Plums, especially the former, are very thin. Our soil, a light and dark on a gravelly subsoil.—JAMES MAITLAND.

IRELAND.

Fruit Crops in King's County.—Apples are very scarce throughout the district, and they are daily dropping from the trees; the only sort which is doing well is the New Hawthornden, a variety which seldom misses bearing a crop here on our heavy clay. Pears and Plums are an average crop, but late; it is doubtful, indeed, whether or not they will ripen. Peaches on open walls are in a pitiable plight; the trees are like so many dead sticks with a bunch of green leaves on their tops. Cherries are an average crop and fine. Red and White Currants are abundant, but Black ones are almost a failure; the trees were badly blighted in the spring, and dropped both foliage and fruit. Raspberries and Strawberries have been very abundant; I never before saw such crops of these as we have had here, but, owing to the continual downpour of rain, they were deficient as regards flavour. Nuts are very promising. Figs are scarcely in leaf yet.—T. J. HARR, *Birr Castle Gardens, Parsonstown.*

Powerscourt, Enniskerry, Wicklow.—Fruit crops in this district, with the exception of small fruit, are a long way under the average. Never in my experience have I seen a more promising show of blossoms with a worse result. With us Pear trees on walls seem to carry something approaching a satisfactory crop, but in the open garden they are almost a failure. Apples are rather better, but nothing near what we were led to expect from the beautiful late display of blossom with which they were furnished.—W. FORBES.

Headfort, Co. Meath.—I have but a poor account to give of the fruit crops in this neighbourhood this year. In the spring I expected to have had an unusually good crop of all kinds of fruit, for all our trees were covered with blossom. Peaches and Nectarines set their fruit in thousands. Apples and Pears were a grand sight when in bloom, but the hail storms which we had in May completely riddled them; now Peaches, Nectarines, Apples, and Pears are far below the average, and the fruit is very small. Strawberries plentiful, but could not ripen, there being so much rain and no sunshine. Raspberries are a fair crop. Red Currants plentiful, but small. Gooseberries the same, and not ripe yet. Of Black Currants we have very few. Cherries are an average crop, with the exception of Morellos, which have nearly all fallen. In fact, it is as bad a fruit year as it possibly could be.—J. CLEWS.

GARDEN DESTROYERS.

THE VAPOURER MOTH.

(ORGYIA ANTIQUA.)

THE caterpillars of this common little moth are sometimes very abundant, and are then very destructive to various plants in gardens, shrubberies, and orchards. Though they do not confine their attentions to any particular kind of plant, they are especially fond of fruit trees, Limes, and Roses. There is not, unfortunately, much that can be done towards destroying this insect; the eggs are not sufficiently conspicuous to make it worth while to search for them. The caterpillars are best destroyed by picking them off the plants they are feeding on, or spreading a large sheet or cloth under the trees or bushes and shaking or knocking the caterpillars into it, when they can be easily collected and killed by pouring boiling water over them. Search should also be made for the female moths, which differ very much from the males in general appearance and habits; having no wings, or only the smallest rudiments of them, they are quite incapable of flight, and their movements being very sluggish, they are very easily caught when found; but as they are of a dull greyish-brown colour, it is not very easy to detect them.

The males can be caught in a common butterfly-net; they may frequently be found flitting about even in the brightest sunshine in search of the females. Of course the earlier in the season the moths can be caught the better, as it is very desirable that as many as possible should be destroyed before they have had opportunities of

Orgyia antiqua (male).

Orgyia antiqua (female).

Orgyia antiqua (caterpillar).

pairing; and if a few females can be killed before they have laid their eggs, the number of caterpillars will be much less. There are several broods of this insect during the summer and autumn. The eggs laid by the females of the last brood do not hatch until the following May, and the first brood of moths make their appearance in June; and from that time to the end of September or the beginning of October there are several broods. The moths are most common in August and September. The caterpillars are exceedingly curious and beautiful, being ornamented with tufts of hair, which vary very much in appearance on different parts of their bodies. When fully grown they spin round themselves a cocoon of silk mixed with hairs, within which they become chrysalides. This insect belongs to the family Arctiidae, and may easily be distinguished from any other member of the family by its rather peculiar form and colouring. The males measure about 1½ in. across the wings when they are fully expanded. Their general colour is reddish-brown. The fore wings are short and broad, and are marked with three irregular transverse darker bands; the exterior one is nearly straight, and is placed

near the margin; the middle band nearly meets it at the lower margin of the wings. At this point, between the two bands, is a somewhat crescent-shaped white spot; the lower wings are of a reddish-yellow colour, and are larger in proportion to the upper ones than is usually the case. The antennæ are large and very deeply toothed. The females are about ½ in. long and very stout, and of a greyish-brown colour; they have only the most rudimentary wings; they seldom move far from the cocoon from which they have emerged. The caterpillars, when fully grown, are about 1½ in. long; they vary very much in general colour from blackish to pale greyish-blue and white. Their bodies consist of twelve joints, of which the first three, the sixth, seventh, eighth, ninth, and last each have a pair of legs; on each joint are several tubercles, from each of which springs a tuft of long greyish hairs, in addition to which, on either side of the first joint, is a tuft of long hairs directed forwards; these hairs vary considerably in length, and are much thickened at the tips. The fifth joint is furnished with two similar tufts, one on either side; and the eleventh joint is provided with one of the same description on the centre of the back inclined backwards. The fourth and following three joints have on the back of each a thick short brush of hairs, which are all of the same length and generally white or yellowish in colour, but sometimes they are grey, reddish, or nearly black; between each of the brushes is a transverse black line on the back. G. S. S.

ANSWERS TO CORRESPONDENTS.

Palms for the Open Air.—"F. C." (p. 133) may safely venture to plant *Chamerops Fortunei* out of doors in any part of Berkshire, or, indeed, any part of England, for it is perfectly hardy, having withstood the late severe winter with us in a very exposed spot without the slightest protection of any kind whatever. Soil and situation have a good deal to do with the endurance of plants, but this Palm appears to do almost equally well in sunshine or shade, provided it can be accommodated with a loose, moist root-run, in which it greatly delights. Before planting, therefore, I should advise for the ground to be well broken up, and to have a good dressing of rotten manure, or leaf-mould, or both, worked in towards the bottom, on which the plant will be able to feed after it becomes established. The leaves being of large size, and on that account holding a good deal of wind, it is necessary to choose a sheltered site to grow it in, as otherwise it is almost sure to get knocked about and disfigured, which detracts much from its beauty. The present season can hardly be regarded as favourable for turning it out, as before it gets fairly hold of the ground winter will be upon us, and it can scarcely be expected to stand so well under such circumstances. If planted in the spring the whole growth will be made outside, where the leaves not only come stouter, but get more mature, in which condition they will bear more cold and frost without suffering. *Corypha australis* is too tender to stand out without a covering of some kind, and even then it is not satisfactory; but the Metake Bamboo is quite hardy, and is a capital plant for shrubbery borders, or to place near the margins of ponds or lakes, where, from its reed-like character, it looks quite at home.—S. D.

Salt and Worms (p. 138).—The readiest way to get rid of these on lawns without damaging the grass is to have a large tub or other vessel and put into it a quantity of unslaked lime, say an eighth or so of what it will hold, and then fill it up with water, which, after it has been standing a short time, may then be drawn off and used. The best time to apply it is immediately after heavy rains in the autumn or spring, or when from the great number of earth casts it can be seen the worms are near the surface where they can be reached quickly by the liquid, which, as soon as it touches them, makes them wriggle out of the ground on to the surface, when they may quickly be swept up and destroyed. If a tap or plug is put in the tub just above the lime, the water may be drawn off clear and the vessel filled again before being finally emptied to make a fresh lot, as the second or even third brewing will be quite strong enough to do the work required. An ordinary garden watering pot with a moderately coarse rose answers well to pour the liquid on with, the point being to distribute it regularly over every part. Corrosive sublimate is likewise used, but this requires great care in handling and should only be applied at the rate of 1 oz. to every 50 gallons of water.—S. D.

Salvia patens Shedding its Buds (p. 162).—This is said to be due to poverty of soil. In my garden at Eton I gave up growing it owing to this habit, which *Lupinus polyphyllus* also had there. The soil there was poor, and robbed by the roots of Elm trees. In my garden here, where the soil is strong and retentive, I grow both plants without any similar trouble.—C. W. Dod, *Edge, Malpas*.

Chimonanthus fragrans—When should this be pruned? During the last two years it has flowered but little, and I fancy it ought to be pruned at this time of year.—M. P. [The pruning had better be done after the fall of the leaves in autumn.]

Peach Shoots.—F. G.—The Peach shoots sent simply illustrate the effects of the remarkable season which we have experienced. Numerous allusions to trees injured in a similar way will be found in the fruit reports published in our present issue.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE INDOOR GARDEN.

THE SAW FERNS.

(*NEPHROLEPIS.*)

THESE are called Saw Ferns from the serrated arrangement of their pinnae. They include several very ornamental species and varieties, and possess a peculiar type of foliage, which they bear in greater profusion than any other class of Ferns. As regards distribution, they are chiefly confined to the Tropics of both the New and Old Worlds, though one species has a much wider range, being found in both North India and New Zealand. All the species have simply pinnate fronds, with their pinnae jointed to the rachis, and numerous slender aerial rhizomes proceeding from the bases of the stipes; they, however, differ greatly from each other in the size and texture of their fronds. The spores of some of the species produce plants freely, while those of others rarely germinate. They, however, all produce offsets from the nodes of the rhizomes, which afford a continual supply. These rhizomes ought to remain attached to the parent plant until the offsets have formed roots and fronds, as the rhizomes of these Ferns never produce offsets after they are detached. A few of the species bear tubers similar to small Potatoes, which, when mature, send forth fronds, thus affording another mode of propagation. These Ferns have hair-like roots, and prefer a spongy soil free from lumps, such as a mixture of sandy peat, light loam, and leaf-mould in equal proportions, passed through a coarse sieve. Good drainage is essential, and they (the evergreen kinds, at least) should never be allowed to become dry, or they will shed their pinnae. They delight in a moist heat when growing, and require very little root room. The genus comprises ten acknowledged species and numerous varieties, which supply us with some of our most elegant stove Ferns; the dwarfier kinds are eminently adapted for decorative purposes, and the larger-growing sorts make noble showy specimens. Those indicating the principal characteristics of the family and best worth cultivation will be found in the subjoined enumeration:—

Nephrolepis acuta, which is known also as *N. ensifolia*, is a robust erect-growing species, and the tallest of the series; the fronds are from 2 ft. to 5 ft. in length, and from 6 in. to 12 in. in breadth at the widest part, tapering gradually to both extremities. The rachis when young is clothed with a greenish fur, which afterwards becomes dark brown. The pinnae, which are inserted their own width apart from each other on the rachis, are linear lanceolate in outline with acuminate points; they are also wavy and of a dull green colour. The fertile pinnae occupy the upper portion only of the fronds, and the sori are arranged in a single row between the margin and midrib. This species thrives well in the shade, and if allowed surface room quickly forms a dense mass of green foliage. *N. hirsutula*, a pleasing variety of this covered with a woolly tomentum, makes a more suitable pot plant than the type. The species itself is common to the tropics of both hemispheres.

N. exaltata.—This is connected by a series of intermediate links with *N. acuta*, from which it differs mainly in size, form, and texture of its pinnae. It is an erect-growing species, with fronds from 2 ft. to 4 ft. in length, and from 2 in. to 5 in. in breadth. The pinnae—which are cuneate, oblong in outline, coriaceous in texture, and of a shining green—have a pair of auricles at their base which bring each pinna on the same side in contact; they gradually diminish in size towards both extremities of the fronds, the upper ones becoming linear and the lower ones triangular. One of the most distinct varieties of this species, *N. Barteri*, was discovered by Mr. Barter in the Niger Expedition. It has drooping fronds, with broad triangular falcate pinnae, which are bluish-green in colour, and

frequently ornamented with a row of white dots within the margin on the upper surface. This variety is confined to West Africa, but the type has the same distribution as *N. acuta*.

N. cordifolia.—This is met with more frequently in collections than any of the other species, probably owing to its prolific rhizomes. Its fronds grow from 1 ft. to 3 ft. in length and from 1 in. to 2 in. in breadth; they are linear in outline and taper abruptly towards each extremity. The pinnae are oblong, slightly falcate, and overlap each other at the edges; they also have a pair of unequal-sized auricles at their bases, which extend beyond the rachis on the under side and overlap the auricles of the opposite pinnae; the fertile pinnae, which in this species occupy three-fourths of the frond from the point downwards, are regularly crenate, while the barren pinnae are serrate. The sori are large and kidney-shaped, and the rachis, being very flexible, causes the fronds to droop both sideways and backwards. *N. tuberosa*, a variety of this species, differs from the type only in bearing tubers; the type and variety are cosmopolitan in the tropics.

N. pectinata.—This, at once the most delicate and beautiful of the genus, deserves to be more extensively cultivated than it is. In structure it resembles *N. cordifolia*, but it is much smaller and produces a greater abundance of foliage. Its fronds, which are of a uniform width throughout, and from about 12 in. to 18 in. in length, are not more than 1 in. in breadth; they are furnished with from fifty to sixty pairs of pinnae of a light green colour. It is one of the best for cutting, and makes an excellent basket plant, its slender drooping fronds and innumerable thread-like rhizomes producing a fine effect. It is a native of Tropical America.

N. davallioides.—In dimensions this resembles *N. acuta*, from which it is difficult to distinguish in a young state; but when both arrive at maturity *N. davallioides* may be recognised by the dimorphic character of its fertile fronds. These fronds terminate abruptly; the uppermost eight or ten pairs of pinnae are pinnatifid and recurved, and bear a sorus upon each lobe; all the barren pinnae are lanceolate and entire, and diminish in size towards the points of the barren fronds. It is a Fern which has a majestic appearance in a mature state; it is one of the best for pot culture, and may be used for similar purposes as *N. acuta*. This species is a native of Java. The crested variety, named *N. davallioides furcans*, is most likely a sport of a variety of this species, as, apart from its abnormal character, it differs materially from the type in structure; its fronds, which grow to a length of from 2 ft. to 3 ft., are lanceolate in outline, and are gracefully arched; the pinnae are from once to four times forked, mostly channelled, and in the fertile pinnae the divisions are more numerous; the sori are quite round, and are situated midway between the margin and the midrib of each division. The whole plant is of a light, shining green, and it grows luxuriantly. It is a valuable addition to our decorative Ferns, and one which should be in every collection.

N. philippinensis.—This is probably a geographical variety of *N. cordifolia*, but very distinct in character from that species. Its fronds, which rarely exceed 15 in. in length, are very rigid, and are furnished with numerous linear, oblong, dull, bluish-green pinnae. A peculiarity of this Fern is a tendency of the upper pinnae to point downwards, like the legs of compasses. It produces offsets freely, and is most suitable for small collections. It is a native of the Philippines.

N. Duffi.—This remarkable monstrosity is a sport of some unknown species. Those parts which approach the normal state closely resemble *N. trichomanoides*, a species not in cultivation. It grows from 9 in. to 15 in. in height. The primary rachis is divided into two or three secondary ones near the base, each of which is again divided near the points into numerous divisions, which separately resemble an entire frond of *Asplenium viride*. The pinnae vary in form from round to oblong, and all the upper ones are deeply crenelled. It forms a compact and very ornamental plant. It thrives best in a shallow pan with the soil raised in the centre, and it requires full exposure to light. It is a native of Duke of York Island.

N. pluma.—This differs from all the preceding in being deciduous. It forms in the course of its growing season several roundish-oblong tubers, which, being of a watery character, require to be kept moist during the resting period, or they shrivel and lose their vitality. The fronds are linear, recurved, and very unequal in size, varying as much as from 1 ft. to 3 ft. in length, and from 2 in. to 4 in. in breadth, on the same plant. The shorter ones stand upright, while the longer ones, having a flexuous rachis, droop gracefully all round, a circumstance which gives the whole plant a feathery appearance. The pinnae, which are of light green, are linear-falcate in shape, and regularly crenelled, with a conspicuous kidney-shaped sorus on each lobe. It seems to be quite at home planted either in the ends of hollow Fern stems, or in the crevices of walls; it is,

however, best adapted for hanging baskets, where its many attractions can be seen to advantage. It is a native of Madagascar and Johanna Island.

C. M.

WINTER AND SPRING FLOWERING ANNUALS.

EVERY one who has a greenhouse likes to have it as cheerful looking as possible during the winter and spring, and no plants aid more at these seasons in rendering such structures gay than a few pots of well grown annuals. Although not the showiest, the favourite amongst these is

Mignonette, which is always welcome, and doubly so during the dull seasons of the year, when there are so few sweet-scented flowers to gratify us in that respect by their presence. Mignonette, however, is by no means an easy plant to grow, for though it is almost a weed out of doors, it is somewhat "miffy" in pots, and amateurs and others who have not had much experience in cultivating it in that way often experience some amount of difficulty in getting it into a satisfactory condition. The most frequent causes of failure are insufficient drainage, and as a natural result too much wet at the roots, from which no plants suffer so quickly, and from whose ill effects none recover more slowly, than that just named. This is more particularly the case during its earlier stages, a time when great care is required to keep it healthy and growing. The finest pots of it I ever saw, that is for the size they were in, were prepared as follows: First of all, they were well drained by having $\frac{1}{2}$ in. or so of finely broken crocks placed in the bottom, over the large one covering the hole, and on the crocks a sprinkling of Sphagnum for the purpose of keeping them clear. Next came a pinch of soot and pigeon manure, after which the pots were filled firmly with rich fibry loam, and the seed sown thinly over the surface, and slightly covered with finely sifted soil. The advantage in placing such highly stimulating manures low down, is that the plants do not feel their influence till they require such help, which is when they have filled the pots with roots, and are coming into flower; and as they do not want much water in winter, assistance cannot be afforded them very frequently in a liquid form, but when the soil is dry it should always be given. By shifting the plants and affording plenty of root room, gigantic specimens may be produced; but although these are fine in their way, they are not so useful for general decorative purposes as those of a moderate size; 6-in. or 8-in. pots are quite large enough to contain from three to five plants each, which if stopped once, and the laterals trained by being staked out, form fine masses, that come in admirably for window embellishment, or for furnishing a quantity of bloom for cutting. For the next two months or so the best place to grow Mignonette is a cold frame, where the lights can be withdrawn by day and tilted by night, so as to give plenty of air to prevent it from drawing up weakly. In winter no situation suits so well as a shelf near the glass, either at the ends of the house or up in the roof, where there is free ventilation, it being very impatient of much confinement. *Reseda odorata*, the common kind of Mignonette, is now eclipsed by several new varieties, the best of which is Mile's Hybrid Spiral, that produces spikes of bloom of great length, and is of a fine strong robust habit, which renders it very suitable for pot culture.

Browallias.—Although not very showy, Browallias are valuable for winter work, their light sprays of lovely blue flowers being a great ornament to any bouquet. Except the beautiful little Forget-me-not (*Myosotis dissitiflora*), I know of nothing so choice to work in with Gardenias, *Eucharis*, double white Primulas, or other pale blooms that require a bit of colour to set them off, and were they not worth growing for many other uses, they would be quite so for the above-named purpose alone. The most floriferous is *B. elata*, but the more recent introduction, *B. Roezli*, has larger and finer blossoms, and possesses the best habit for pots. For cutting, however, I prefer the old sort, and it has the additional recommendation of requiring less heat, but to do either well they should not be kept in a lower temperature than from 50° to 55°, or they quickly show signs of distress. To get them strong before winter sets in they cannot now be sown too soon, and to prevent any disturbance or check to their progress when up, the best way is to put three small pinches of seed triangularly close to the sides of some 3-in. pots, that the plants when singled out may be shifted on into others as soon as they require more room. The object in growing them in that way is that being of spare, fragile habit they look best together, and make a finer display should they be wanted for vases, for table decoration, or the embellishment of rooms. A light, rich, vegetable soil consisting of about three parts of leaf-mould to one of fibry loam, suits well to pot them in, as in that their roots ramify freely, and being loose and open it admits of quick drainage, and allows them to be well plied with liquid manure, which enables them to keep up a succession of flowers. Any ordinary frame where they can be shut up early and pushed on by being syringed will answer for the next two

months, after which a temperate house will meet their requirements best for the winter.

Schizanthus.—The variety of these known as *S. papilionaceus* always attracts much notice on account of the great resemblance their many spotted flowers bear to beautiful butterflies with outspread wings, and as they are of very easy cultivation and last a considerable length of time in bloom, I can strongly recommend them to any one who wishes to keep up a rich display in the spring. A packet of seed will yield plants that vary very much in the colour of their blossoms, for, like Balsams, *Cinerarias*, &c., they are very sportive in their character, and to keep up a fine strain the best only should be selected and saved. *S. retusus* *Grahami* likewise yields very handsome flowers, in form greatly resembling some of the choice Orchids, many of which they quite equal in their rich markings. Where it is desired to have them in early, seed should be sown at once, and again for succession at the turn of the year. So serviceable are they for general decorative purposes that we are seldom without them, but have them in all stages, as even in the height of summer they are among the best plants for keeping a house gay that any one can cultivate. Like most annuals they delight in a rich, moist soil, and require abundant supplies of water and liquid manure when flowering.

Rhodanthes.—These are never seen in anything like the state of perfection, or are half so charming to look at, as when grown in pots, their delicate pink, satiny blooms requiring to be elevated to show them off to advantage. They are, therefore, admirably adapted for window boxes or shelves, where they are brought more on a level with the eye, and are very telling in groups of Primulas, Tulips, Hyacinths, and other forced bulbs. The best way to manage them is to sow in pans filled with fine soil, which should then be kept close under glass till they germinate. As soon as they are large enough to handle prick them off into 3-in. pots, placing five or six equidistant in each, after which set them in a close frame and shade for a few days to give them a start. A light, airy shelf in a warm pit or house is the best place to winter them, they being very susceptible of damp, and therefore in watering them care should be taken not to water them overhead or keep them too wet at the roots. At the turn of the year when there is more life and movement in vegetation they will bear their final shift into 6-in. pots, and from that time on it is necessary to keep them growing without check till they attain the desired size, the tendency of *Rhodanthes* being to produce bloom prematurely as soon as the sun has much power, and causes the shoots to become hardened. In a young state they are very subject to green fly, for which they must be watched and gently fumigated directly the insects appear, or they speedily do irreparable injury. I have tried various soils and find peat or leaf-mould and loam, with a sprinkling of rotten manure, to be the best for potting, in which, if kept open by sand, they grow away freely.

Stocks of the Ten-week kinds form admirable pot plants, and are largely grown in that way to supply the London market, and yet it is very remarkable that they are seldom seen except in beds and borders in private gardens. For amateurs and others who like to have gay windows and have not much convenience by way of glass to keep up a supply of plants, these Ten-week Stocks come in particularly handy, as any frame from which frost is excluded suits them perfectly, if they only get plenty of light and air to prevent them drawing or becoming infested with mildew, to which their leaves are particularly subject. As it makes its appearance on the under sides the only way to stop it is to hold the plant sideways and dust the parts affected with sulphur, which destroys the parasite at once. The proper time to sow for winter is the end of July, but good plants may yet be grown if the seed is got in at once.

Godetias.—Last spring I saw some fine specimens of *Godetia*, with which I was much struck, for though common enough in borders during the summer, they were new to me at that early season, and at once showed what a desirable acquisition they are for the greenhouse. The most beautiful is *G. Lady Albemarle*, that has flowers as large as some of the kinds of *Hibiscus*, with richly coloured petals, the inner part of which is as glossy looking as satin. It is seldom that plants bearing such large blooms are very free, but the *Godetias* are an exception, for more floriferous plants cannot be, and as their habit of growth is so close and compact, they are well adapted for pots. Being very hardy, they do best plunged out till late in the autumn, when they can be taken in and wintered in any cold frame.

Nemophila insignis should not be forgotten, as it is quite unapproachable in the fine shade of blue of its flowers, and though old, there is nothing equal to it for suspending in small baskets, or for use as a front edging in stands, where its trailing branches soon droop over and cover the sides. Many others might be mentioned, but those above enumerated are the most desirable, and with them greenhouses may be rendered much more attractive than they usually are during the dull months of the year. S. D.

LOW'S GOLDEN-SEPALLED CYMBIDIUM.

(C. LOWIANUM.)

In habit this plant resembles *C. giganteum*, and was first described by Reichenbach as a variety of that species, from which, however, it differs much both from a botanist's and from a cultivator's point of view. Well-grown plants of it are 2 ft. or more in height, and have gracefully arching, dark green leaves distinctly marked with yellowish veins; the flower spikes, which are nearly as long as the leaves, bear from ten to fifteen flowers, if not even more, each flower, as shown in our sketch, being from 3 in. to 4 in. in diameter. Their colour is novel and therein lies their charm; the sepals and petals are golden green and the lip whitish, with a large blotch of bright velvety red, almost approaching crimson indeed, and most effective in brightening up the whole flower. The plant is vigorous and grows well in a fresh open compost of peat, Sphagnum, fibrous loam, and crocks. It also enjoys a liberal supply of root moisture when growing. Not only is it one of the handsomest of Cymbidiums, but it stands out clearly as one of the most distinctly beautiful of recently-introduced Orchids. It is Indian, perhaps Burmese. F. W. B.

IMPROVED VARIETIES OF CHINESE PRIMULA.

Few plants contribute so much to render greenhouses and the windows of sitting rooms gay and attractive during the dull season of the year as the various varieties of the Chinese Primrose. This Primrose has been cultivated in this country ever since 1820. Since that time, however, it has undergone marvellous improvements, most of which have been effected during the last few years, and this is still progressing, the productions of each succeeding season being in advance of those of its predecessor. To show as far as possible by what means this is being accomplished, and to point out what is considered to be a successful method of treating these plants, will be the object of these remarks.

Culture.

The Chinese Primrose may be increased by means of cuttings, divisions, or offsets; these methods are, however, seldom resorted to in the case of the single-flowered varieties, which are mostly raised from seed, but apply to all the double-flowered kinds, which, as a rule, do not produce seed. This method must also be resorted to in propagating any seminal variety which may exhibit such remarkable merits or peculiarities as may render its increase desirable; but, as has been stated, the single sorts are generally grown from seed, which should be sown during the spring of each year, say about the end of March or early in April, so as to have the plants in the greatest perfection during December and January. Or, if desired earlier or later, the time of sowing may be varied accordingly. The seed should be sown in well-drained pots or pans, spreading a thin layer of Moss upon the drainage to prevent the soil from intermingling with it; the rougher portion of the soil should be placed at the bottom, making the surface perfectly smooth and level and moistening it with a fine-rosed watering pot; while yet moist sow the seed, press it gently down, and sprinkle a small portion of silver sand or fine soil over it. This covering should, however, be very slight, and the surface of the pot or pan should be covered with a piece of glass, which during bright sunshine may be slightly shaded by a thin layer of Moss. The pot may now be placed in a favourable position in any glass structure where a temperature of 60° or 65° is maintained. Thus situated the seeds will soon germinate, and when this has taken place the glass should be removed, but during strong sunshine the young plants should still be slightly shaded, and water should be given as may be found necessary. When the young plants are large enough to be handled, they should be pricked into pans of suitable soil, and afterwards potted singly into small pots. As the season will now be considerably advanced, a close pit or frame will be a suitable place for them, and as soon as they have well filled the small pots they are in with roots they should be shifted into the pots in which they are intended to bloom, and for this purpose pots some

6 in. in diameter will generally be found suitable. If large specimens are desired, pots of greater dimensions may be employed, but handsome plants may be produced in pots of the size just mentioned. The final shift should be given not later than the beginning of August.

The pots used should be well drained, and the soil should be composed of about two parts light rich fibrous loam, and one part well decomposed leaf soil, with a small portion of silver sand; or fibry peat may take the place of the leaf soil and sand. In giving the last shift it is necessary to press the soil rather firmly to the stems, so as to keep the plants steady, as the stem is naturally weak, while the foliage and flowers are heavy, and if potted too deeply the stems are apt to canker off. Whenever it is found necessary, the plants can be readily supported and kept erect by inserting three or four small sticks into the soil, close to the stem, so as to afford it the necessary support, taking care at the same time to avoid injury to the roots. After the final shift has been given, the plants will still be found to succeed best in a cold pit or frame, placed upon a cool moist bottom, which produces also that moist atmosphere which appears to conduce so greatly to healthy development; they should be kept pretty close to the glass, and should not be placed too closely together, so as to avoid etiolation or undue lengthening of the leaf stalks. On this account it is also inadvisable to use anything in the way of permanent shade, although slight shading will be beneficial during very bright sunshine. No material is more suitable to form a bottom on which to place the pots containing the plants than a layer of 2 in. or 3 in. of finely sifted cinder ashes, which will prevent the

entrance of worms into the pots; these soon render the drainage ineffective, and that seldom fails to seriously affect the health of any plant confined to a pot. To still further secure the pots from such intruders, a thin layer of gas lime may be placed under the cinder ashes. The plants should be occasionally moved and placed further apart, as may be found necessary, and they should be kept free from weeds. When the pots are found to be well filled with roots, they should once or twice a week be watered with clear, well-diluted liquid manure, and the plants should be slightly syringed on the evenings of bright warm days. Early in October they should be moved into a greenhouse, or other light, well-ventilated structure. Early in November bloom trusses will begin to appear; and in order

Bloom of *Cymbidium Lowianum* (natural size).

to give the plants additional strength these may for a time be removed. As has been already stated, December and January are the months during which these showy winter-flowering plants are likely to be most appreciated; but they may, nevertheless, be had in bloom by the middle of November, or even earlier, and the same plants, with proper care, will continue in beauty until the end of February. No situation is more suitable for these Primulas than the front of a light greenhouse or conservatory. Still the temperature of such structures should as seldom as possible be allowed to fall under 40°, and the double-flowering varieties especially appear to enjoy a temperature rather higher than that.

Improved Varieties.

As has already been stated, the Chinese Primrose has been greatly improved since the period of its introduction, principally as regards its flowers, although habit and foliage have also undergone considerable improvement. The Fern-leaved varieties were justly considered at the time of their introduction to be a great acquisition, and on several occasions seedling plants have appeared with prettily variegated leaves; but somehow such plants have either been too delicate in constitution to be increased to any extent, or they have not been considered worthy of that attention; therefore, a Chinese Primrose with distinct and well-defined variegated foliage, if really a desideratum, has yet to be secured. It is in the flowers of these now popular plants in which such marked improvement has taken place. When first introduced, they were much smaller than they are now, while in colour they were a light purple or rosy-pink; whether the white-flowered variety originated in this country or was introduced,

I am unable to say. The margins of the corolla, however, in the case of both varieties were plain, and the flowers altogether such as could not be tolerated at the present day. The fimbriated or fringed-flowered variety appears to have been introduced some years after the introduction of the plain-flowered kinds; a plant of the former is mentioned as a new plant, grown in the Horticultural Society's garden at Chiswick, in the year 1824, and it appeared in trade catalogues in 1833, but it was then rare. No attempt appears to have been made to improve the flowers of the plain or smooth-edged kinds, probably on account of the greater beauty of the fringed-flowered varieties; and, as has been already said, the bloom of the latter has been of late years wonderfully improved in all respects, including colour, form, and size. As regards the latter quality, it will be found that a crown piece will fail to cover the blooms of many varieties; while, as respects colour, the most desirable shades have been secured—even a blue-flowered variety is said to be in existence. Continental countries, as well as our own, have contributed towards the improvement of this family of decorative plants, and the method, I believe, generally pursued is that of selection; a portion of the very best varieties are placed together in a favourable position in a light well-ventilated structure, and the fertilising process is left to insect agency and the action of the atmosphere, with possibly the assistance of an indiscriminate distribution of pollen by the aid of a camel-hair pencil. This method, however, although excellent results may have been obtained by it, is, nevertheless, somewhat haphazard, and it is possible that those whose success has been most decided have pursued a more systematic method. The stamens of the Chinese *Primula* are five in number, and are attached to the inside of the tube of the corolla, while the pistil occupies the centre of the flower; and in some plants the style is sufficiently elongated to elevate the stigma to the level of the surface of the bloom, while others produce flowers in which the style is so short that the stigma is concealed by the anthers. This peculiarity occurs also in the kindred families of the *Auricula* and the *Polyanthus*, and is distinguished by the terms pin-eyed and thrum-eyed; and so fatal is the objection to the former condition in a florist's estimation, that the presence of a single bloom having this peculiarity is considered of sufficient importance to disqualify the stand containing it, if shown in competition. The Chinese *Primrose*, however, has not as yet, I believe, been subjected to this somewhat arbitrary law, and it is very certain that its pin-eyed flowers are equally beautiful as those with thrum-eyes. But, be that as it may, they are at least the best suited for the purpose of being made seed-bearers, as foreign pollen can be with greater facility conveyed to the stigma than is the case with thrum-eyed flowers, where it is necessary to remove the anthers or slit the tube of the corolla in order to reach the stigma. And it happens that the blooms of the single-flowered varieties of this plant cannot with safety be subjected to great manipulation, on account of the corolla separating so easily from the calyx.

Seed Saving.

About the end of January or early in February is a suitable time to select a few plants, of the very best kinds, for the express purpose of furnishing seed for the next year's supply, and with, of course, the object distinctly in view of securing improved varieties. All fully-expanded blossoms should be removed, and the plants should be placed in a favourable situation, from which, if insects can be excluded, so much the better; but at this season their interference need not be greatly apprehended. Pollen should now be collected by means of a small brush or camel-hair pencil from the blooms of varieties which may be considered to be most likely to effect the desired results, such as depth of fringe, shade or intensity of colour, size and form of bloom, &c., and should be carefully applied to the matured stigmas of the intended seed-bearing plants. One application to each bloom will be sufficient, and in the case of pin-eyed blooms it will be quite necessary to remove the anthers. When as many blooms have been fertilised as is considered necessary, the plants should not be allowed to continue flowering, but the blooms should be picked off as they appear, so as to prevent exhaustion, and possibly hasten the ripening of the seed.

Double-flowered Kinds.

The double white variety of the Chinese *Primrose* has long been cultivated in this country, as well as a double purple variety, introduced, I believe, at a later period. Both are exceedingly useful for decorative purposes during winter, and, unlike their single congeners, the corolla does not in their case separate easily from the calyx; consequently the flowers remain longer in perfection, and their blooms during winter are quite indispensable for the purpose of forming bouquets, and placing with other cut flowers in vases, &c. In addition to the two varieties alluded to, some greatly improved forms have of late been introduced, having blooms of increased size, double, and well-formed, while the petals are beautifully fringed or fimbriated,

the colour varying from pure white to deep purple. These double-flowering kinds do not, as has been said, usually produce seed; most of them, however, furnish pollen to some extent, but generally rather sparingly, and this being used on the stigmas of some of the finest single-flowered kinds, has resulted in the production of a race of semi-double flowered varieties of great beauty, whose blooms are of a more persistent character than those of the single sorts, and are consequently more suitable for forming bouquets, &c. The flowers are also possessed of perfect stamens and pistils, and if the various sorts are placed by themselves, and fertilised by their own pollen, they will reproduce themselves perfectly true from seed. The double kinds flower generally so very profusely that by the middle of February they are usually somewhat exhausted; then the bloom trusses should be all carefully removed, and the plants should be allowed to rest for a week or two; they should then be shaken from the soil, divided, and formed into cuttings, to increase the stock as may be desired. A strong plant in a 6-in. pot may generally be divided into a dozen or more plants or cuttings, as it is not necessary that each portion should retain roots, as these are readily formed when potted singly into small pots in light, sandy soil, placing the cutting in the centre, and surrounding it with a portion of silver sand, pressing the soil firmly to the stem of the cutting or plant. The pots should now be plunged in a slight bottom-heat in a close pit or other structure, where a temperature not under 65° is maintained. As soon as the small pots are well filled with roots, the plants should be shifted into larger pots as may be found necessary, and during the summer they should be grown in a pit or frame, and treated in all respects as single-flowered kinds which have been raised from seed.

This family of decorative plants is already so rich in the possession of numerous beautiful varieties, that to attempt to still add to them may be considered unnecessary; but if a union can be effected between some of the existing varieties of the hardy *Primula cortusoides*, or dark-flowered varieties of *P. vulgaris*, or the *Polyanthus*—which does not appear to be altogether outside the limits of what may be considered possible—this, when accomplished, will furnish a new and interesting race of *Primulas* of increased hardiness, if not of increased beauty, which can hardly fail to be regarded as an acquisition.

P. GRIEVE, *Culford*.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

***Browallia elata grandiflora*.**—This fine form of the old *Browallia elata* is at this season most useful for conservatory and indoor decoration. It comes true from seed, which should be sown in heat in February or March, and, if the young seedlings be potted on as required, good plants at this season will be the result. Their flowers, being of a beautiful shade of blue, are very valuable for associating with those having bright colours that are usually employed in such structures. It also succeeds well out-of-doors, and makes a pleasing variation amongst ordinary bedding plants.—J. GROOM.

***Anguloa eburnea*.**—There is certainly some confusion about the name of this plant, and I question very much if it is grown in England at all to any great extent. I have seen a plant exhibited under this name which was no other than *Anguloa uniflora superba*. The typical form of *A. uniflora* has dark-coloured pseudo-bulbs and very dark green leaves, the sepals and petals being white and very slightly spotted, and the lip rather more densely spotted with pale red or pink. *A. uniflora superba*, which is also grown as *A. eburnea*, has likewise dark-coloured pseudo-bulbs and leaves similar to those of the other. The flowers, too, are similar, with the exception of being nearly twice as large in all their parts. Has any one ever seen an *Anguloa* with ivory-white flowers? I think not. Mr. Williams states that he has only seen the true *A. eburnea* in the late Mr. Dawson's collection at Meadowbank, near Glasgow, but he says the lip was spotted with pink, the sepals and petals being pure white. J. DOUGLAS.

—Possibly "Z." (p. 165) is correct in supposing that the true *Anguloa eburnea* is not in this country. The plants which I have had under that name, and that I have seen elsewhere, do not differ from *A. virans*.—T. BAINES.

Antiquity of Orchids.—"If we take into account," says Mr. Wallace in *Nature*, "the world-wide distribution of these plants, their immense richness in genera and species, and their wonderful complexity of structure, we must consider them as among the most ancient instead of among the most recent of flowers." Wetterhan writes: "Out of fifty species of Orchids in Gareke's 'German Flora' not less than forty-one occur in the British Isles," besides two not found in Germany, "a proportion exceeding that of phanerogams generally. Now as it seems scarcely credible that Orchids should possess means

of transportation across the sea in preference to other plants, we must conclude that they inhabited the British Isles before their separation from the Continent, which involves that they have occupied stations near the present coasts of Germany or France previous to a great deal of plants that reached these coasts only subsequently to the formation of the Channel." He also adduces the fact that the British Orchids belong to very different groups of the Order, enhancing the argument for antiquity based on their geographical distribution. — "Bulletin of the Torrey Botanical Club."

THE FLOWER GARDEN.

FUCHSIA RICCARTONI AND ITS USES.

THIS fine old Fuchsia still ranks amongst the best of what are called hardy Fuchsias, if not of all outdoor flowering plants, for it grows on heedless of inclement seasons. Its beautiful blooms are produced in, if possible, even greater profusion in a season like this, that may truly be termed flowerless, than under more favourable circumstances.

in the very worst of seasons, if we be content with plants that flourish under ordinary conditions. It is the attempt to introduce plants from the Tropics, simply because they are expensive and more difficult to cultivate than those of temperate climes, that makes such blanks in our fashionable displays. This would perhaps be a favourable time for any one who is desirous of having a really enjoyable garden to make notes of all failures and successes during this hitherto exceptional season, and, in order to prevent disappointments in future, to discard all doubtful subjects, giving a prominent place to humbler but possibly more deserving plants. If this were done, I feel sure that Fuchsia Riccartoni would hold its own in the list either as a hedge plant or for single specimens on Grass, or as a wall or pillar plant, when the old wood should be spurred in like that of a Vine; or, if allowed to ramble at will in the wild or woodland garden, it will be found equally satisfactory. J. GROOM.

Linton.

Tiger Lilies in the Wild Garden.—The annexed engraving represents a group of the common Tiger Lily (*L. tigrinum*) growing in the wild garden at Great Tew, Oxfordshire. In such a situation

Tiger Lilies in the Wild Garden at Great Tew, Oxfordshire.

We have a hedge formed of large clumps of this beautiful Fuchsia overhanging a sunken wall, and most beautiful it looks either from the park or garden side. Although the old ripened wood of this Fuchsia will withstand ordinary winters, last winter's severe and protracted frost was too much for it, as it was killed down close to the ground; but this is no drawback, as I find that it always makes by far the best-looking and freest flowered plants when pruned down quite close in winter. After that the borders should be cleaned and a little manure forked into them about the roots of the plants.

This Fuchsia also looks well planted in hollow tree stumps cut into 2-ft. lengths and let into the soil about 6 in. Through these, if filled with good soil, the Fuchsias soon root into the solid earth below, and require no attention in the way of watering, as they are perfectly self-supporting and self-protecting. As single specimens on Grass, too, or on the margins of shrubberies this Fuchsia is equally at home, and when once planted it gives no more trouble, accommodating itself to our fickle climate better than most of our bedded plants have done of late years, as a season that suits our sub-tropical beds ruins our moisture-loving Calceolarias; therefore those who have but a limited space for ornamental gardening should decidedly select their plants from amongst those that defy the weather even in its worst moods. Happily there is no need for flowerless gardens even

Tiger Lilies grow with unusual vigour, as the soil in which they are placed is kept at a uniform condition as regards moisture, and the surrounding herbage also protects very considerably the young shoots in spring from the baneful influence of harsh winds, which are so detrimental to all kinds of Lilies. Indeed, this mode of growing Lilies would be attended with more success than in the bare and often exposed borders in the garden, where they are rendered susceptible to every atmospheric change. Besides, their bold flower-laden stems rising from amidst coarse herbage have a charming effect in the landscape, and one that only needs to be seen in order to be appreciated. —W. G.

Veronica Traversi.—This plant has long been known in the west of England, even in cottage gardens. In Mr. Ellacombe's garden at Bitton, where it forms large bushes, it, as elsewhere, has withstood the severe winter untouched. The same plant was sent out some years ago as *V. devoniensis* by Messrs. Veitch. By the way, there are many hedges of a very pale bluish New Zealand Veronica now in free bloom in cottage gardens in North Devon. They have a delicate odour. There are no doubt other forms besides Traversi which will be found to suit colder localities. The New Zealand Veronicas are very beautiful in southern gardens, and where they thrive a variety of kinds should be grown.—V.

JAPAN LILIES AT HOME.

FIRST comes *Lilium auratum*, or as some term it, the Queen of the Lilies, and more term it the Golden-rayed Lily of Japan. This is the common wild Lily of Japan, and when I first came here in 1864, one could not go out anywhere in spring without seeing this beautiful Lily growing in the woods and on the sides of hills. You would find it almost everywhere you went. You could see it in all its beauty, the stems averaging from 3 ft. to 12 ft. high, and the flowers numbering from three to one hundred and seventy-five on a single stem. I have seen stems more than 3 in. round. Sometimes, if the bulb is very old, they will throw up a round stem to about 3 ft. or 4 ft., when you will see it commence to get flat, and as the stem grows, so it gets wider and wider. I have seen them often as much as 6 in. wide at the top. The flowers from these stems far exceed those of the round stems in number, but not in quality, being much smaller. There is another good quality belonging to this Lily; it is quite hardy and will live through almost any weather; but I would advise those who grow it in very cold parts in open borders to protect it somewhat from the frosts, or to take it up out of the ground altogether and place it in a flower-pot, and put it in any cold place for the winter. Your bulb will then be good when you wish to plant it next spring. I know of no flower, with the exception of the *Olea fragrans*, that has so strong a fragrance as *L. auratum*.

L. auratum pictum is a seedling from *L. auratum*, and if you plant a bed of the latter you will often find one or two *L. auratum pictum* among them. The flower of this, instead of having a yellow band as in *L. auratum*, has a reddish band about half way down the flower. The growth and habit are just the same as those of *L. auratum*.

L. rubro-vittatum.—This is a seedling also from *L. auratum*, and it is the prettiest of them all. The flower is as large as that of the original, and has the same growth in every particular, the difference being in the flower only. Instead of the yellow band, as in *L. auratum*, this has a beautiful glossy red band, sometimes with spots and sometimes not.

L. auratum, var. virginale is another seedling from *L. auratum*. The flowers are pure white with the exception of the yellow rays, which are unusually brilliant, and a few scattered spots of pale lemon colour. This also, like its parent, is hardy, and if you did not see it in flower and saw this and *L. auratum* growing together you could not tell the difference.

L. kamschatcense (Black Lily).—This is called the Black Lily on account of the flowers being nearly black, but to speak the truth the flowers are a very dark purple, with very small yellow stamens. The flowers themselves also are small, and I have never seen more than three on a stem, and the stem never more than 1 ft. high.

L. concolor.—This has small star-shaped flowers of a light scarlet colour, dotted with dark red spots. It is very rarely that you find more than two flowers on a stem, and it does not grow more than 2 ft. high. The flowers stand erect.

L. coridium.—This is a seedling from the above, and only differs from it in the colour of the flower, which is yellow.

L. cordifolium giganteum (or *japonicum*).—I may say here about this plant, that unless you get very good bulbs indeed, you cannot get them to flower, and the best place to flower them is under shade in a shrubbery, for they do not like the sun. It grows well in a moist stiff soil. The bulb that you plant this spring is not the bulb you dig up in the autumn. The bulb you planted last spring, as soon as the flower-stem was out of the ground, had formed its own roots, and the bulb decayed altogether, and about the time of flowering, if you take one up, you will find that the new bulbs are just forming at the base of the stem. The leaves of this are very much like those of the Beetroot, but not quite so long. The first leaves come out at the surface of the ground, and when the stem is about 18 in. out of the ground it pushes a ring of leaves out all around, and out of the centre of these the flower-stem grows. The flower-stems average in height from 5 ft. to 7 ft., and I have never seen more than eight flowers on one stem in its wild state. The flower has four petals and is very long; the petals turn out like those of *L. eximium*, but are smaller in size. They are of a white creamy colour, tinged with a dash of light purple in the two upper petals.

L. japonicum.—This is a beautiful Lily, but quite a distinct variety from any of the others. The foliage is thick and stumpy, and darker glossy green than that of any of the others. The flowers are trumpet-shaped, and measure about 6 in. in length. They are pure creamy white in the interior, but sun-painted outside with a rich chocolate brown. This is one of the finest varieties, and is well worth having; it attains a height of from 3 ft. to 5 ft.

L. krameri.—This is another very fine variety, which no garden should be without. The flowers are inclined to be long, but not so much so as in the preceding sort. Those of some are of a most delicate pink, some are darker, some are pure white, and some are white with a small tinge of pink. This Lily throws up a stem from 3 ft. to 6 ft. high, and has from four to twenty-five flowers. It thrives in a light, dry, peaty soil. It will rot where another bulb will thrive.

L. leichtlini.—This like the above is one of the best varieties; it has the slenderest stem of any of the Lilies compared with its height. The flowers are a golden yellow thickly dotted with purple spots. The ends of the petals curl backwards on to the stem. The average height is from 3 ft. to 5 ft., and it will produce from eight to twelve flowers.

L. longiflorum eximium is the common long, white, trumpet-shaped flowering Lily. It is common, but it makes a very good Lily to mix with others in a bed. It grows from 2 ft. to 4 ft. high, and will produce from five to ten flowers on a stem.

L. longiflorum foliis albo marginatis.—This is a seedling from the above and was raised by a Japanese gardener; it only differs from the preceding by having a narrow, even, white border round the leaf.

L. martagon.—This is quite a distinct variety from any of the others, the flowers being much smaller, and inclined to curl backwards. They are yellow, with dark spots in them. The foliage resembles that of *L. japonicum*. The plant attains a height of from 2 ft. to 5 ft., and will produce from six to seven flowers right on the top of the stem.

L. medeoloides.—This is another Lily well worth growing, but a very hard one to travel if not properly packed, as the bulbs are formed of small round leaves, and if one is not careful in handling them they fall to pieces. The leaves are quite different from those of any of the others, being formed in circles around the stems. These attain a height of from 2 ft. to 4 ft., and never produce more than six or eight flowers. The colour is orange-red with dark spots.

L. speciosum rubrum.—This is another very fine Lily and well worth cultivation. It is also very hardy. The flowers, which are red with a strip of Pea green in the interior, curl backwards; they also have a margin of white and are spotted with red.

L. speciosum album.—This has the same habit in every particular as the preceding, the only difference being that the flowers are pure white with a small stripe of Pea green up the centre. The height of the stem is from 4 ft. to 6 ft., and it produces from twenty-five to thirty-five flowers. These are the two latest to flower.

L. thunbergianum fl.-pl.—This is a dwarf, hardy variety, and one of our few double Lilies. The flowers are a fiery-red with dark spots; the outer petals being much larger than the centre ones. It very seldom grows more than 18 in. high, and never produces more than three or four flowers on a stem. It is one of the first to bloom.

L. t. marmoratum.—This is a single variety of the above. The flowers are a deep orange-red, with irregular tawny stains, chiefly at the tips of the petals, giving them a splashed appearance.

L. t. tatzla.—This is a little larger in growth than the last. It will sometimes grow to a height of 4 ft., and will bear from five to seven flowers right on the top of the stem; but the flowers are quite separate from one another; that is, they do not touch each other like some kinds. They are light yellow in colour, tinged with pink.

L. t. bemy.—This is another of the above family, but quite distinct from any of them in colour and foliage. The flowers are a very dark chocolate, turning almost to black; they are erect.

L. t. alice wilson.—This is quite a new variety of the above. I sent one bulb of it to London in 1875. It was sold by auction to Mr. Wilson, of Heatherbank, who flowered it in 1876 and named it as above. The flowers are a light orange-yellow, and stand erect.

L. tigrinum fl.-pl.—This is another of the few double varieties which we have, and one of the latest to flower. The petal decreases in size towards the centre. It is a very robust grower. The flowers, which are fiery-red in colour, are marked with large purple spots. It is the finest among the double varieties.

L. t. splendens.—A single variety of the above, and, if anything, a little taller. These two, like *L. speciosum rubrum* and *album*, throw out small bulletts in the apex of the leaf. I would just mention here that *L. album* and *L. tigrinum fl.-pl.* and *L. tigrinum splendens* are used by the natives as a vegetable.

I would also add here for the information of those who would like to grow the Black Lily and *L. medeoloides* and have not been successful in their attempts, that *L. medeoloides* must be grown in a very light peaty mould, mixed with a little sand, and the same with

the Black Lily. The same mould will do, but do not let them get too much water. If you do you will be sure to lose all you have. All the remainder of the *Liliums* are perfectly hardy and will grow in almost any garden soil, but as I have stated above, where it is very cold it is best to take them up in winter and store them in any dry place where it does not freeze. I would also add, that if you wish for fine flowers, you must use good soil mixed with well-rotted manure. The Black Lily should be put in pots not more than 6 in. deep, and about midway in the pot.—*California Horticulturist*.

THE RAMONDIA-LIKE CONANDRON.

(CONANDRON RAMONDIODES.)

THE annexed engraving is a representation of this rare plant, a specimen of which was exhibited at South Kensington a short time ago by Messrs. Veitch & Sons, when it was awarded a botanical certificate. The illustration gives a good idea of the general habit of the plant, though the peculiar wrinkled appearance of the leaves is not shown very clearly. The leaves are fleshy in texture, and spring from a fleshy, brownish rootstock. The colour of the blos-

Conandron ramondioides (half the natural size.)

soms is pale lilac, with the centre of a much deeper hue and spotted with yellow, the tuft of stamens being also yellow. There is also a variety with white flowers introduced. The extreme rarity of this plant much enhances its interest, and it is, moreover, very remarkable from a structural point of view. It grows at high elevations on mountains in the southernmost island of Japan, where it was recently collected by Mr. Maries, who is travelling for Messrs. Veitch. Naturally it prefers moist rocks, and this is a point that should be observed with regard to its cultivation. Though it is grown in frames in Messrs. Veitch's nursery at Coombe Wood, it is most probably as hardy as the pretty *Haberlea rhodopensis*, of which a woodcut was given in these columns a short time since, and which is nearly related to this plant. Hardy plants of the families to which these belong are very scarce in cultivation at present, though amongst them many are really beautiful, and might be advantageously introduced. The seeds of Himalayan *Cyrtandraceae* plants distributed from Kew last year may perhaps produce some very welcome results, as many from the regions from which they come ought to be hardy, and from what may be gleaned from the elaborate drawings in Mr. C. B. Clarke's recent work on Bengalese *Cyrtandraceae*, many of them must be very beautiful, and ought to be a source of much interest both to the botanist and cultivator.

W. G.

FLOWER GARDENING IN BATTERSEA PARK.

EVEN if this fine park were shorn of its most noteworthy attraction—the annual display of bedding plants and its famous sub-tropical garden—it would still be highly picturesque, and excel all the other public parks on account of its excellent design, which embraces well diversified lawns, extensive and varied water margins with luxuriant aquatic vegetation, natural-looking rockeries, and, above all the permanent beauty afforded by the rich collections of trees and shrubs, remarkable both for their handsome foliage and beautiful flowers, which during spring form the principal source of attraction. Indeed it is generally admitted that the most appropriate season to see the real beauty of this park is in early spring when the majority of the trees and shrubs are in bloom. Another noteworthy feature, too, in this park is the prevalence of hardy, fine-foliaged plants grown either as isolated specimens, or in some prominent position at the margin of the shrubberies. The most noticeable amongst these are *Polygonum sachalinense*, a grand plant growing from 8 ft. to 10 ft. high; *P. cuspidatum*, which is now bearing a profusion of pretty white catkin-like blossoms; *Gunnera scabra*, *Arundinaria falcata*, various kinds of *Acanthus*, *Echinops*, *Grasses*, besides a host of the finest foliaged shrubs, such as cut-leaved *Elders*, *Tamarisk*, golden and variegated varieties of the commoner shrubs and trees. The handsome *Aralia spinosa*, *Ailantus glandulosa*, and *Aralia Sieboldi* are used extensively, and few more desirable shrubs could be found. Shrubs now in bloom comprise the beautiful Chinese *Privet* (*Ligustrum sinense*), and the Japanese kind (*L. japonicum*), both very sweet scented. Single flowered *Roses* such as *Kosa nitida* are very attractive, as are also huge bushes of the double-flowering *Bramble* with its pretty pink rosette-like flowers. *Pavia macrostachys* and several kinds of *St. John's Wort*, including the beautiful Himalayan *Hypericum patulum* and *Spiraea Nobleana*, are also very strong. The groups of *Jackman's Clematises* are now very gay masses of colour, varying from pale to a deep violet-purple. In one part they are allowed to ramble over branches, which shows off their beauty to advantage. Those overhanging the ledges of the rocks are also very attractive with their brilliant flowers mixed with *Ivy* and other plants. It is, however, much to be regretted that there is such a paucity of the finest of hardy herbaceous plants, which would seem to be quite ignored here. During the present season especially their absence is conspicuous on account of the dearth of bloom of the bedding plants. The many unoccupied places caused either by the failure of the tender plants, or scarcity of bedding material, could be most advantageously filled with showy hardy plants, which would not fail to be a source of considerable attraction, and if not in flower throughout the four seasons, they would relieve the dull monotony of bare earth which prevails during two-thirds of the year. Attention is now being directed to improving the old rockery which skirts the Albert Bridge Road. The picturesque dells have been very tastefully planted with all kinds of plants likely to succeed in such situations, and when established will render this portion of the park one of the most beautiful and interesting.

The Mixed Alpine Garden exhibits very markedly the untoward season, as the incessant wet has almost rotted the majority of succulent plants which usually form such a conspicuous feature here. The "snowy" mounds covered with the dwarf creeping *Antennaria tonnentosa* still look very effective, as do the mounds near them which are clothed with a great variety of plants, one of the most conspicuous being the beautiful Himalayan *Astilbe rivularis*, an elegant *Spiraea*-like plant with long feathery flower stems, tiny white flowers, and bold handsome spreading foliage. *Bonapartea*s, *Aloes*, *Agaves*, *Beaucarneas*, *Mesembryanthemums*, and a host of other similar subjects are planted here, but, as before remarked, their appearance is but indifferent. The rare *Yucca Whipplei* is doing well and probably will eventually prove a serviceable plant. The surface of these mounds is carpeted with the *Turfing Daisy* (*Pyrethrum Tchihatchewi*) and the elegant *Leptinella seariosa*, various *Stonecrops*, &c. The Fern banks are quite as attractive as in former seasons, though the tender *Palms*, *Succulents*, &c., even in these sheltered places show signs of the unfavourable weather.

Sub-tropical Beds.—However much care might have been bestowed in the selection of suitable tender plants for producing a sub-tropical effect in the open air during the present unfavourable season, the result is much inferior to that of former seasons. All, with the exception of the hardiest, have done but moderately well. The belts of *Cannas*, *Polymnias*, *Wigandias*, *Solanums*, the *Castor Oil* plants, and similar subjects have grown only about half their usual height, whilst, on the other hand, the season has been favourable for the luxuriant growth of hardy plants such as the various kinds of *Funkias*, which since the spring have been the leading ornament of flower gardens. Their handsome and often beautifully variegated foliage and their pretty mauve-tinted blossoms render them highly desirable for gardens of all sizes. The plants arranged in groups beneath the shade of the trees are much the same as those

noticed on former occasions. They consist principally of large growing Aroids, Palms, Bromeliads, Ferns (both tree and stemless), Musas, Cannas, and similar subjects. An interesting feature and one that is apparently much appreciated is the mixed beds of tender plants disposed without any definite arrangement. These comprise plants of considerable diversity as regards habit and flowers, and they come from all quarters of the globe. Here Australian plants are represented by Grevilleas, Callistemons, Acacias, &c. The gaudy Mexican Tiger Flower (*Tigridia Pavonia*) is pre-eminently conspicuous, as well as the graceful *Desmodium penduliflorum*, a most desirable shrub for warm situations. The old-fashioned *Fuchsia fulgens* and other tender kinds thrive well and flower freely, as do also different sorts of *Abutilons*, *Lilium auratum*, the showy *Kalosanthes coccinea*, and various other plants. Large specimens, too, of the elegant *Sonchus laciniatus* with its feathery foliage give an air of lightness to the beds. Near these is a bed particularly striking and much admired; it consists of a groundwork of the variegated Vine (*Vitis heterophylla variegata*) studded with small plants of the elegant *Grevillea robusta* and edged with the variegated *Honeysuckle*, *Sedum*, and *Alternanthera*.

Carpet Bedding.—Except in the case of the partial failure of such tender plants as the *Alternantheras*, this style of bedding looks fairly well here this year, the present moist season having been favourable to the growth of most of the plants employed. Some oblong beds especially, which are near the entrance to the sub-tropical garden, are characterised by delicacy of finish, the subjects being well chosen for the purpose. The design consists of a series of circles of various sizes; the plants used are *Alternanthera versicolor*, *A. paronychioides*, *A. amœna*, *Echeveria secunda glauca*, *Sedum glaucum*, and *Mentha Pulegium gibraltarica* (which has succeeded admirably everywhere this season). Several similar beds are also attractive, the designs being well defined. The artistic arrangement, too, of some of the circular beds is noteworthy, especially those in which is planted a circle of neat examples of *Dasyliion*. There seems to be nothing new or uncommon in the way of plants applicable for carpet bedding, except a golden-leaved variety of the Round-leaved Cranesbill (*Geranium rotundifolium aureum*), a neat-growing kind, but not golden this season owing to the continued wet. From the same cause the coloration of the foliage of many of the plants used is by no means so rich as in former seasons—such as that of the Golden Stitchwort and Golden Feather *Pyrethrum*.

The *Pelargoniums* and other flowering bedding plants are, as is everywhere apparent this year, far below mediocrity, and the cutting of the plants for propagating purposes has not improved their condition. The brightest and most successful set of beds of this kind are those representing a fan-shaped device near the Chelsea Bridge entrance. Their forms are well defined, and, with but few exceptions, all the plants have thriven moderately well.

W. G.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Selaginella helvetica.—This is the name of a very neat, dwarf, compact-growing *Lycopod* I saw recently at Messrs. Sutton & Sons' Reading Nursery, where it has the reputation of being entirely hardy, as it was stated that it had stood all the previous hard winter in the open air in Germany without suffering. This variety presents an intermediate form between *denticulata* and *densa*, and would, if proved hardy here, make a capital rock plant, as it produces a firm, close carpet of growth. It is something to the credit of this kind that it looks hardy, but that may be incidental, the plants being now in a cold frame and treated as hardy. Should it be found to be all that is expected, this *Lycopod* will prove an interesting and valuable addition to our hardy carpet plants, and might be largely used in decorative bedding.—A. D.

Hydrangeas Planted out.—The *Hydrangea* is a plant which one seldom meets with really well grown, yet it is capable of the very best effects, and well repays any extra attention which it receives—a statement which may be easily proved by the superb small specimens that London market growers yearly send to Covent Garden about this time of the year. But when grown into large plants its strong, gross-feeding roots soon impoverish the soil, and unless the latter be well supplied with liquid manure the blooms become small and the foliage sickly. Having several such plants that were too large for indoor decoration, I planted them out last autumn in a very exposed position as an experiment, and the wood being well ripened they braved the inclement weather of the past season well, and are now covered with a fine display of bloom-heads. We have beds of them in several different positions, and I find that those in sheltered and rather shaded places suffered more during the winter than those fully exposed, as the young wood was soft

and immature. In a season like the present such a beautiful flowering plant as this—one that is capable of producing a lasting and cheerful display of fine flowers while the ordinary summer bedding plants are completely washed out—deserves a little more attention than it has hitherto received. Before planting, the beds should be deeply trenched, but if the soil be of good quality little manure should be applied at first; but after they get established and have done flowering the old weakly wood should be well thinned out and a good top-dressing of manure should be applied annually.—J. GROOM, *Linton*.

Preparing for Spring Bedding.—Where this is carried out, many of the subjects employed will now need attention. Plants in the seed beds, such as Wallflowers, Stocks, Forget-me-nots, &c., will require transplanting into single lines. Cuttings of *Alyssums*, *Aubrietias*, *Pansies*, &c., must be put in; and seeds of various sorts, such as *Silenes*, *Virginian Stocks*, and *Nemophila*, must be sown. Bulbs that have been laid in to complete the ripening process will need cleaning, and others should be purchased for making good deficiencies, as, however bad the season may be, good bulbs may be relied on to produce a fine display, and their gorgeous colours go far towards making an effective spring garden.—J. G.

Tuberous-rooted Begonias.—I am pleased to see so much said in favour of these plants; they cannot be too highly praised. Those at Messrs. Veitch's which I saw were simply splendid, especially one called, I think, *Monarch*, but there were so many and all so beautiful that I might possibly have made a mistake. If not *Monarch*, that is what it should have been, for it was *monarch* of all I saw. I am growing some few, and have flowers on some of them which measure $\frac{3}{4}$ in. in diameter. Those who have to furnish a conservatory at this time of the year would find these plants invaluable; they are so easily grown and stand so well that they put *Pelargonium* completely into the shade. I have no decoration now, but still I grow them, and have been this day amongst them with my camel's-hair brush, for I expect something better.—JOHN CLEWS, *Headfort, Kells*.

Nasturtiums as Screen Plants.—At this season of the year the tall-growing varieties of *Nasturtium* make extremely effective screens for hiding unsightly objects. If planted against strained wire netting or any kind of support, they will train themselves with but little attention, provided the shoots are occasionally regulated, in order to keep them from becoming matted together. In addition to their good foliage, their bright cheerful flowers of many shades of colour continue to be produced in abundance until the early frosts bring the floral display of tender plants to an end.—G.

The Eulalias.—These Grasses are very handsome now in the Bitton collection. *E. japonica variegata* is perhaps the handsomest variegated Grass yet introduced into England, as the variegated *Arundo Donax* does not thrive everywhere. *E. zebrina*, with the curious broad bands across the leaf, is also remarkably striking at this season, when the markings come out more clearly than earlier in the year.—V.

Mixed Sweet Peas.—Amongst the brightest plants in the garden at present are some mixed Sweet Peas. They were procured in packets of separate colours, scarlet, white, purple, &c., and sown evenly in rows, the result being a very beautiful mixture of colours. They should have good rich deeply-cultivated soil in which to grow, and as soon as they are well up they should be earthed and staked, and if dry weather ensues a good mulching should be given along each side of the row and copious supplies of liquid manure, keeping the seed pods picked off closely.—J. GROOM.

Eschscholtzia Mandarin.—This deep-coloured variety of the old bright yellow *Eschscholtzia* is very pretty for beds or borders. If sown in March in well-prepared ground it will keep up a continuous display during the whole season.—J. G., *Linton*.

The Canadian Moonseed.—This is one of the many climbers the effect of which is usually destroyed by being nailed against walls or similarly despoiled of any grace which they possess. Freely trained over an arch in the garden at Bitton, and hanging down in wreaths, it looks a climber worthy of a place in a garden.—V.

Phlox Vau Houttei.—We notice this beautiful old striped *Phlox* in the garden at Bitton. It has been lost in many collections, including that where it originated. It deserves to be carefully propagated and made plentiful.

Amaryllis Acramani.—This fine *Amaryllis* proves as elsewhere quite hardy in Mr. Ellacombe's garden at Bitton. A hardy *Amaryllis* which is also very handsome should be taken note of.—V.

Androsace Lageri.—This is a charming dwarf, tufted, densely-branching plant, 2 in. to 3 in. high, bearing a profusion of pale rose-coloured flowers nearly throughout the month of May. There is a coloured plate of it in "*Regel's Gartenflora*," t. 969, where it is stated that it differs from *Androsace carnea* in its more densely-branched, dwarfer habit, &c. It was not however, as Dr

Regel supposes, an unrecognised species, having been described by Huet de Pavillon some twenty-five years ago. Previously it had been confounded with *A. carnea*, from which it is very distinct from a gardener's point of view. The leaves are almost as fine as those of *Spergula pilifera*, and, like that plant, the short, intricately branched stems form a close tuft, from which the flower-stems rise about 2 in. or 3 in. high. Individually the flowers are small, but they are borne in clusters of six or eight at the top of the naked stalks, which are so numerous that the plant is a mass of flowers. There is also a good plate of this in Jordan & Fourreau's beautiful "Icones," t. 766. It is a native of Mount Do in the Southern Pyrenees, and succeeds with very little trouble in half-shaded spots in the rock garden.—W. B. HEMSLEY.

Anometheca cruenta.—In gardens on free soils this neat and bright little plant often grows so freely as to become almost naturalised, and is then very pretty as a flowering carpet to other subjects.

Veratrum viride.—The true plant is not often grown in gardens under this name. There is now a plant of it at Bittou 8 ft. high, bearing a huge drooping panicle of seed vessels. It is a very striking hardy fine-leaved plant.—V.

THE DODDERS.

THE entangled masses of small wire-like tendrils which are often seen in fields twining round the stems of other plants belong to annual leafless parasites known as Dodders, species of the genus *Cuscuta*. They are very mischievous to crops, which they soon destroy.

Clover Dodder.

Nearly half a hundred different kinds of Dodder are known, and of these there are four or five distinct kinds indigenous to this country, though on this point authorities differ. These are the Great Dodder (*C. europaea*), with much branched stems of a red or greenish-yellow colour, and small white flowers tinged with red, borne in clusters about the size of large Peas, and produced towards the end of the summer. It is rather rare, and grows on Hops, Nettles, Vetches, Thistles, &c. A second kind is the Lesser Dodder (*C. Epithymum*), which has very slender, bright red or purple stems and dense clusters of flowers tinged with rose colour and very pretty in appearance, as they lie in patches on Furze, Heath, Thyme, or other dwarf shrubby plants. It flowers at about the same period as the foregoing, and is not so uncommon. The Clover Dodder (*C. Trifolii*), which is represented in the accompanying woodcut, is considered to be a variety of the Lesser Dodder, though easily recognisable by its singular partiality for strangling the common red Clover. It is so prevalent in some localities that whole fields have been destroyed by it. It first appears in small patches, but in a few days covers large spaces. The Flax Dodder (*C. Epilinum*) is so called on account of its singular propensity for attacking fields of Flax, and the extent of the mischief caused by it in some districts during favourable seasons for its growth is very considerable. It is about the size of the Great Dodder, but usually more pale and with more fleshy stems. It is not a native plant, and it is said to have been introduced from other parts of

Europe with foreign Flax seed. *C. hassiaca*, which attacks Lucerne, and *C. approximata* are sometimes met with, but by no means common. W. G.

PROPAGATING.

PROPAGATION OF LAPAGERIAS.

IT is now over thirty years since the rose-coloured variety of this plant came into England, and when first it bloomed with Messrs. Veitch, the distinct form and colour of the flowers and the general habit of the plant at once gave it a high position in the estimation of plant-lovers. In due time it was distributed, and when it got a little cheaper I obtained a plant of it which was anything but large. It was a little wiry tough-looking specimen in a 6-in. pot, with a shoot about 3 ft. long, that did not convey the idea of its being a subject that would acquire strength at anything like the rate many plants do. I repotted it as soon as it had made roots in sufficient numbers to warrant its being benefited by having more room, and in the succeeding spring it pushed up a shoot considerably stronger than the one which it at first had, and which grew to some 7 ft. before it stopped; it was again shifted in spring. I knew nothing about its propagation, but was anxious to increase it, and the following year I took off a couple of young shoots with a heel to them, *i.e.*, made from near the top of the preceding season's growth, and inserted them in the usual way, but they both dwindled off. The shoot made that season was much thicker and larger than that produced the preceding one. In autumn I cut off a portion of the current year's fully-ripened growth and made it into cuttings. Several consisted of a couple of joints and two or three of the stoutest one joint each (or, as is more usually expressed, a single eye) cut just below the joint, but with as much length of shoot above it as could be got below the upper eye. These, kept cool, moist, and covered with a propagating glass, took several months to "callus," after which they were placed in a little warmth, and about half of them grew; but the shoots which they made were no thicker than a darning needle, and they were several years before they attained strength enough to make much progress, although they pushed up a shoot each from under ground each spring in the way natural to the plant. I have given above the details of my experience in striking this plant from cuttings, which I believe was similar in result to that of others who have tried to increase *Lapagerias* by this means. It is evident that little or nothing can be done in propagating them from soft immature shoots, and the wood is naturally so hard and wiry that, even when rooted from cuttings made from the fully-ripened wood, the growth produced is so weak that it takes years longer to get the plants up to a reasonable strength, such as is obtainable by means of layers in a much shorter time.

Two years afterwards I layered a couple of the strongest shoots of the original plant in the way practised by trade propagators, allowing the rest of it to remain in its position on the shady end of the greenhouse. I followed the course suggested to me by one who had had a good deal of experience in propagating the *Lapageria*; I got a box some 6 ft. in length by 3 ft. in width, and 10 in. deep, with the usual holes in the bottom. Into this I put 2 in. of drainage materials, and filled up with good fibrous peat, made fine, with sufficient sand added to it to admit of water passing off freely. The surface was pressed quite smooth and the shoots pegged regularly down upon it, bending them round so as to cover the space evenly. On the shoots I laid about ½ in. of soil similar to that with which the box was filled, made quite fine, and pressing it moderately. All the leaves were kept erect and had their base in the soil to the depth at which the shoots were covered; the layering was done, so far as my memory serves me, about the beginning of November, when the season's growth was fully hardened; the soil was kept fairly moist through the winter, and as the spring advanced the young shoots began to appear aboveground, but not from every joint. There was considerable difference in their strength, the largest coming from the strongest portion of the layered shoots near their base. The whole were taken off and potted singly in the autumn, and they were afterwards treated in the usual way.

"J. S. W." speaks (p. 132) of the propagation of the white variety of *Lapageria*, which is in no way different from that of the red one; he says that it will probably be found the best to propagate them like Vines from eyes; but I do not think his expectations will be realised. The character of the two plants is very different; that *Lapagerias* can be increased from single joints (eyes) is correct, but the growths resulting from such are so weak that they take too much time to attain the strength possessed by layers. A Vine eye will make as much progress in a few weeks as the layered bud of a strong shoot of *Lapageria* will do in as many months. The process

of development in these layered *Lapagerias* is very different from that of most plants; after layering, the bud swells to about the size and shape of a newly-formed *Camellia* bud, and then, before it makes any further progress, or shows above ground, it forms a tuft of roots which push their way into the soil before the shoot appears above the surface. The Handsworth Nurseries spoken of by "J. S. W." have, as well as a few others, been for years noted for their successful treatment of these plants, but few propagators of *Lapagerias* will be prepared to accept "J. S. W.'s" statement when he says that "plants reserved from last year's young stock have now ten shoots or more." Even in the case of the very strongest it takes some time before more than one or two annual shoots are made. The habit of *Lapagerias* in this respect is more like that of the *Bomareas* than any other plants with which I can compare them. Will "J. S. W." give us a little further information respecting these young Handsworth *Lapagerias*?
T. BAINES.

NOTES OF THE WEEK.

Burbidgea nitida.—This is one of the most beautiful of the novelties in Messrs. Veitch & Sons' nursery, Chelsea, where it has been in flower for some time. It belongs to the *Ginger* family, and grows from 2 ft. to 10 ft. high. It has somewhat slender erect stems, scantily furnished with bright green leaves of leathery texture, attaining from 4 in. to 6 in. in length. The flowers are produced in terminal panicles, consisting of from twelve to twenty blossoms, which vary from 1½ in. to 2 in. across, the rich orange-scarlet segments forming a triangular outline. It is a native of Borneo, where it was first discovered by Mr. F. W. Burbidge, in compliment to whom it is named. It grows in shady forests in the north-west part of the island, at an elevation of from 1000 ft. to 1500 ft.

Calandrinia nitida.—Amongst rock plants this is a perfect gem when grown well, and one that is yet scarcer than it should be. It grows from 6 in. to 9 in. high, and has ovate lance-shaped leaves which are very glaucous. The flowers are 1 in. or more across, of a rich violet-purple hue, and are produced in loose racemes. It is numerously represented on the rockery at Mr. Ware's nursery and is now in full flower.

Pentstemon Clevelandi.—This has succeeded better at Kew this season than hitherto, and has shown off its beauty to very much better advantage. The tall raceme of flowers has grown nearly a yard high; their peculiar hue is scarcely describable, but probably the nearest approach to it is pure magenta, a colour rarely seen in wild species. All the *Pentstemons* seem to have thriven better this year than usual, a fact probably owing to the wetness of the season.

Phlomis cashmiriana.—This very rare Labiate is represented by a large clump in the Hale Farm Nurseries, Tottenham, and is now finely in flower. It is of dwarfer habit than any of the better-known kinds. It is herbaceous, and somewhat resembles *P. Herba-venti*, but the flower-heads are denser and the flowers larger, and they have a broad violet-purple lip. It is by no means new to cultivation, having been introduced many years ago, and well figured in the "Botanical Register."

Lilies at Chelsea.—A house in Messrs. Veitch & Sons' nursery filled with pot plants of *Lilium auratum* and *L. speciosum* and its varieties, is now a sight worth seeing. It shows well the adaptability of these lovely plants for conservatory decoration, though they are not so extensively used for such a purpose as they should be. At this season it would be difficult to name a more suitable class of plants, for, combined with their showy flowers, they are elegant in habit and their blossoms emit a delightful perfume.

Habenaria pycodes.—This is one of the prettiest of the hardy North American Orchids. Its flower spike, which grows about 1 ft. high, has its upper half furnished with a raceme of violet-purple blossoms, the tips of which have a delicate fringe at the edges which renders them very attractive. It seems to thrive admirably in peaty soil on the rockery at Mr. Ware's nursery, where it is now finely in flower.

Orchids at Kenwood, Albany, N.Y.—Amongst the rarer kinds of Orchids now in flower in Mr. Corning's garden at Albany, are *Phalenopsis violacea* and *P. Lobbi* (*P. intermedia* var. *Portei*), two of the rarest as well as most beautiful of the *Phalenopsis*. The superb *Cattleya exoniensis*, *virginialis*, and *Brabantie* are likewise well represented, as are also *Epidendrum Wallisi* and *dichromum*, which are amongst the most distinct and beautiful kinds belonging to this large genus. Two desirable varieties of *Miltonia* are *Regnelli purpurea* and *Moreliana atrorubens*, and one of the loveliest of all the *Dendrobiums* is *D. Macarthei*, but unfortunately it is a somewhat difficult plant to manage, though it succeeds well

here and flowers freely. An interesting variety of *Oncidium* is *O. prætextum*, a kind apparently intermediate between *O. crispum* and *O. Forbesi*. *Stenia finbriata*, a terrestrial sort, is a perfect gem, and one which should be in every collection. *Ionopsis paniculata* and *Bifrenaria aurantiaca* are very showy when grown in large masses, but they are rather scarce. *Cypripedium niveum* is unusually strong here, several stems bearing three flowers. The cool house is particularly gay at this season with the large-flowered variety of *Epidendrum vitellinum*, *Disa grandiflora*, various kinds of *Odontoglossum* and *Masdevallia*, &c.—F. GOLDRING.

Ellacombe's Yucca.—This superbly-beautiful plant is now in fine flower at Bitton, and deserves to be made more common. With the precious qualities of hardiness, fine form, and abundant bloom, common to the other *Yuccas* of the *Y. gloriosa* type, it has the additional charm of a rich suffusion of reddish-crimson on the outside of the flowers. This makes the effect of a stately pyramid of its flowers one of the finest to be seen in the garden. It does not seem to differ much from, and is at least quite as ornamental as, the *Y. superba* of the "Botanical Register." Messrs. Osborn, of the Fulham Nurseries, have, or used to have, a stock of this plant, and they would do a service to gardens by increasing it.

Spigelia marylandica.—A fine example of this scarce North American plant is now in full flower in the herbaceous ground at Kew, where its long, deep, blood-red and yellow blossoms are singularly beautiful. Seldom is it seen growing in such a mass, but it did not attain such a size at Kew; it was brought from a garden in Berkshire about a year ago, where it was growing in a fully exposed, sunny border, planted in a stiff loamy soil without a particle of peat. Now that it is put in peat it is showing signs of deterioration, evident proof that it requires different treatment—that it either lacks the bracing climate of the Berkshire hills, or that peat does not suit it so well as a loamy soil.

Lilium longiflorum and its Varieties.—Mr. Ware has sent us flowers of this fine Lily from his nursery at Tottenham, in order to show the marked difference that exists between the flowers of *L. longiflorum* and the variety *eximium* when well grown. The superiority of the latter is very apparent, but both are well worth growing. Mr. Ware has now seven distinct varieties of *L. longiflorum*, which vary in the time of flowering, thus affording a succession of blossom for at least five weeks, a fact which considerably enhances the value of this superb Lily. It is also perfectly amenable to gentle forcing, and by this means the flowering season may be much prolonged.

Berberidopsis corallina.—This is one of the most attractive amongst the wall plants at Kew at the present time. It is growing against the wall of the T-range, where it has been for some years, and where it has withstood the past winter unhurt. It has been aptly named the Coral Plant, on account of the similarity of its pretty drooping, red flowers to coral. Though it has been introduced to our gardens from Chili for nearly a quarter of a century, it is by no means so frequently grown as its merits entitle it to be, as few more desirable plants could be recommended for embellishing the roof of a greenhouse, where it succeeds far more satisfactorily than in the open air.

Bonapartea juncea in Bloom.—There is at present in a stove at Seapark, Morayshire, a large specimen of this old-fashioned Peruvian plant in full flower. It is growing in a 15-in. pot, the soil used being loam with some brick dust. The stem or trunk is about 2 ft. in circumference, from which spring the Rush-like leaves averaging 22 in. in length; the flower stem rises to a height of 10½ ft., and of that 7 ft. are furnished with flowers of a greenish white colour, each about the size of a single Hyacinth pip; the stamens are double the length of the flower. There are upwards of 500 flowers on the plant.
—WM. MACKIE, *Seapark, Forres*.

Gloriosa Plantii at Chelsea.—This beautiful climbing plant is very attractive just now in the stoves in Messrs. Veitch's nursery, where it is growing in moderate-sized pots. The main shoot, which is trained to the rafters for about 8 ft. of its length, subdivides at that height into branchlets which hang down gracefully and bear an abundance of blossoms. The latter have a striking appearance, owing to their singularly twisted, reflexed petals, which, when first expanded, are greenish-yellow, gradually changing to a bright orange-scarlet. A variety named *grandiflora* is much superior to the older kind, its colour being far more brilliant. Considering the adaptability and the easy culture of this climber it ought to be more frequently grown in stoves and greenhouses than it is.

Thyme on Rockeries.—In reference to your correspondent, who has just discovered the value of wild Thyme on a rockery, I would remark that it was about the first plant which I admitted on my own thirty years ago, but I soon found out that *T. hirsutum* was superior to it.—CHARLES ISHAM, *Lampport Hall, Northampton*.

Spikenard of the Ancients.—In “Notes of the Week” (p. 164) it is stated that a plant growing in Mr. Ware’s nursery at Tottenham, named at Kew *Nardostachys Jatamansi*, is the Spikenard of the ancients. This is a mistake; the Spikenard of the ancients is a species of Grass called by Linnaeus *Andropogon*, now called *Nardus indica*, the oil from which is called by the natives of India *Rhonsee ke Teel*. The oil is obtained from the spikes, which, when ripe, are cut with a portion of the stem about 1 ft. in length, and are then subjected to distillation. It is a native of many parts of India; those which grow about the Jaum Ghaut are preferred, and are gathered in the month of October, when the seeds forming the ears or spikes have become fully ripe.—G. S. WINTLE, 10, *Paragon Grove, Surbiton*. [The majority of writers on Scriptural Botany consider that *Nardostachys Jatamansi* constituted the Spikenard of the ancients.]

The Striped Musa (*M. vittata*).—This is one of the handsomest of the cultivated species of *Musa*, and also one of the scarcest. It is, however, grown in quantity by Mr. Ley of the Croydon nursery, where it is highly effective when mixed with other fine-foliaged plants. *M. zebrina* is another beautiful kind, and also a scarce plant. The large black blotch on its bronzy-tinted leaves has a singular appearance, and affords a striking contrast to the striped *Musa*, with its rich green leaves elegantly variegated with pure white bands.

The Tiger Flower (*Tigridia Pavonia*).—A large space in Mr. Bull’s nursery at Chelsea devoted entirely to this gorgeous Mexican bulbous plant now presents a dazzling sight, several hundred flowers opening daily. There is, too, considerable variation in the size and brilliancy of the flowers—so much so as in some cases to justify a varietal distinction. *Tigridias* are plants of the simplest culture, merely requiring to be planted in spring and taken up in autumn and kept in a cool dry place during winter.

The Yellow-flowered Lobelia (*L. Intea*).—Some beds of this *Lobelia* in Messrs. Veitch’s nursery at Chelsea are now in fine condition; the plants are covered with bloom, and a few fine days would render them very attractive. The flowers are as large as those of most of the bedding *Lobelias*, and of a bright yellow colour. The only detracting point about it appears to be its somewhat straggling habit, which could probably be improved by hybridising it with some more compact growing sort.

Papaver umbrosum.—This handsome Poppy is the most brilliant sight in Messrs. Barr & Sugden’s grounds at Tooting. In general appearance it somewhat resembles the common field Poppy (*P. Rhœas*), but the flowers are considerably larger and of a more intense scarlet, with the addition of a large black shining blotch at the base of each petal, which is the chief point of distinction. At Chiswick, too, it has been the admiration of every one for some time. It is apparently an annual, and is of the simplest culture.

Bravoa geminiflora.—In order to see the full beauty of this fine bulbous plant it requires to be seen in such a mass as is now at its best in the Hale Farm Nursery, Tottenham. It is several yards square, and the brilliant scarlet colour of the long tubular flowers, which are borne in pairs, renders it one of the most attractive plants in this nursery.

The Canadian Elder.—This is an important addition to flowering shrubs. We saw a bush of it at Bitton a few days ago, well furnished with very large spreading heads of white flowers. The bush was not above 5 ft. high. It would be valuable for planting on a lawn by itself, near but not quite on the margin of a shrubbery. This partial isolation would prevent its being overgrown, destroyed, or weakened, as is the fate of so many rare or beautiful shrubs and low trees.

The Californian Laurel.—This handsome evergreen, which helps to make the “foothills” of California look in many cases like a choice pleasure garden in a favoured district in southern England, has formed in Mr. Ellacombe’s garden at Bitton as fine a specimen as we have seen of it in its native country. Having survived the late severe winter, when so many plants were killed, there can be no doubt as to its hardiness, in Gloucestershire at all events. It may be as well to state here that this shrub (*Oreodaphne californica*) emits when bruised an odour of a very dangerous character, to the extent, indeed, of producing paralysis in some persons.

A New Feature in Window Blinds.—A novel form of window blind, and one likely to come into extensive use in shading greenhouses, frames, &c., has lately been invented by Mr. Paul Metz, of Hamsell Street, E.C. It is made of small round strips of wood painted green, and so arranged that they form a flat surface, which, whilst it admits ample ventilation and light, effectually shades. It is light and elegant in appearance, and may be folded with as much facility as blinds of calico or similar material, and it possesses the advantage of not requiring to be washed. For offices and dwelling houses such blinds would answer admirably.

LIQUID MANURE AND ITS APPLICATION.

THERE are times of pressure in the lives of most cultivated plants, when a good soaking of liquid manure would be exceedingly beneficial. The lives of fruit trees may be prolonged, and the fruit improved in size and quality, by administering liquid manure just at the time the greatest demand for support arises. Solid manures are not immediately available for the plant’s use; time must be given for air and water to do their work and draw out the essences or strength of the manure, and present it in a suitable form for conveyance by the roots to that part of the tree which for the time being is making the greatest demand. This being so, it will readily be seen that, in times of great pressure, liquid manure may render valuable aid. The times when extra help will be most acceptable are when the produce for which the plant is cultivated is undergoing the process of formation and development. A plant or tree grown solely for its fruit will require support most when its fruit is about half-grown, and immediately following the stoning period in the case of stone fruits. A liberal supply of liquid manure will enable a tree to carry a much heavier load with less inconvenience to itself. I believe, in the majority of cases where fruit trees are weakly in habit and growth, with puny fruit and small pale-coloured foliage, that a good soaking twice a week at this season, if the weather be dry, of soot water, will soon put new life and vigour into the foliage and wood of the tree; and without good substantial foliage a tree cannot produce good fruit. Dressings of soot over fruit borders in showery weather, in autumn or spring, will be beneficial; and soot water, clarified with lime, makes an excellent insecticide as well as a valuable stimulant. Water is an excellent carrier; it places within reach of the roots at once anything that is soluble, and thus enables the cultivator to give his crop of fruit, flowers, or vegetables, as much food as they require. And after a season like the present, when the land, both in garden and field, has been literally washed out with the almost constant downpour of rain, the benefits of a liberal application of liquid manure to advancing crops of Apricots, Peaches, and other late fruits, to give size and quality, will be very considerable. Vegetables, too, after the washing the land has had, will appreciate any help that can be given to them in this way. Liquid manure, from its nature, is quick in its action, and need not be given till it is required, or till the plant is in a condition to absorb and assimilate a strong liquid; indeed, this is the only time when liquid manure can be used with profit. To give it to small, young, or weakly plants may do harm, by clogging up the soil, and so rendering the plants unhealthy; but if applied freely to plants having an abundance of roots, its effect will be seen almost immediately. To plants in pots, such as orchard-house trees carrying a heavy crop, some help in this way is indispensable if the best results are to be obtained. And the same remark applies with equal force to flowering plants of a robust nature, such as Fuchsias, Chrysanthemums, Balsams, &c. For Melons and Cucumbers soot water is very suitable; it seems to impart a strength and vigour to the foliage that helps to ward off the attacks of red spider and other pests. The term “liquid manure” may include everything, from the waste of the laundry or dwelling-house to the solutions of highly concentrated manures prepared by the chemist. There is a good deal of highly valuable manure wasted in nearly every house. What becomes of all the slops or horse waste? Why, it usually finds its way into the sewer, and in country houses, instead of being arrested by a tank and pump, it is usually conveyed to some ditch to contaminate the atmosphere. The necessity for growing larger crops of better produce, in order to meet foreign competition, will no doubt in time cause more attention to be given to this subject. In the case of any delicate-rooted subject, such as Azaleas, &c., liquid manure, when it is desirable to use it, should be given clear—*i.e.*, free from all earthy matter—containing the essence of the manure; and perhaps in such cases guano, or some artificial compound that leaves little sediment, will be best to use. When sheep or other animal excreta are used for making liquid manure, it is best to prepare it in a tank, or some other large vessel, that has a division with holes in it, shutting off a part of the tank. In this part so separated the manure should be placed, and the water, being poured over it, will percolate through the holes in the partition, carrying the strength of the manure with it in a clear limpid condition, or at least without anything to choke the spouts of the watering pots, or to clog up the pores of the soil and make the plants unhealthy. Soot may be tied up in an old manure bag and placed in the tank, and renewed when exhausted of its fertilising properties. The liquid can be clarified by dropping in a good-sized lump of unslaked lime after the soot has had time to become mixed with the water. I don’t know that it is necessary in any case to give exact quantities; but it is best always to make the liquid strong, and dilute at the time of using, giving it weak and often in preference to strong doses. Whenever liquid manure is given to crops in the open air, or to the borders of fruit houses, the surface should be mulched, or, supposing the water has been applied late in the afternoon or

evening, should be freely stirred and loosened upon the following morning.
E. H.

— A very common query is, "How can I make liquid manure?" And it is one that is variously answered. The compilation of these liquid compounds must largely depend upon the materials employed—that is, whether they be of some centralised form such as is found in guano, or whether they are of simple raw manures. One of the best and safest fertilisers for pot plants, especially those that are of a robust, leafy habit, such as Zonal Pelargoniums, Balsams, Cockscombs, Gloxinias, Begonias, &c., is made solely from cow-manure, and if a large tank is at disposal for the purpose, a couple of barrow-loads of fresh, raw manure should have applied to it about 100 gallons of water, and should be allowed to stand three or four weeks before using. If the manure be entirely free from straw or other foreign matter there will be no floating particles to choke the waterpot or foul the soil for the plant. After each using some more water equal to the portion taken away should be added, the whole well stirred, and then the liquid will be clear again when it is once more required for use. From time to time a barrow-load of fresh manure may be added, to maintain the feeding properties of the liquid up to the required standard.—A. D.

THE LIBRARY.

CONTRIBUTIONS TO AMERICAN BOTANY.

BY SERENO WATSON.

THE ninth part of this valuable work has just reached us. It contains, in addition to descriptions of several newly discovered plants for the most part not yet in cultivation in this country, a complete revision of the North American Liliaceæ which cannot fail to be useful both to the botanist and cultivator, as the descriptions are so lucid and the general plan of arrangement so excellent. Many species and varieties are enumerated in addition to those described by Mr. Baker in his revision of the Order a few years ago in the Linnean Society's Journal. We infer from the descriptions that several of these newly discovered plants are very handsome and that they will prove desirable acquisitions; we therefore hope soon to see them in cultivation. Much diversity of opinion exists with regard to nomenclature, a circumstance to be regretted, as nothing adds more to the confusion that already exists with regard to plant names than the differences of authorities in such matters. In the work under notice inconsistencies in this respect are strikingly apparent; take for instance two or three of the genera to which popular garden plants belong and compare them with those given in Mr. Baker's work. In *Calochortus*, which is essentially a North American genus, Mr. Baker enumerates twenty-one species, three varieties, and several forms differing but slightly from the types. In the recent revision several of these forms are ignored, whilst in others they are made distinct species. *C. Maweanus* of Leichtlin, considered by Mr. Baker as a form of *C. elegans*, is ranked by Mr. Watson as a species. *C. elegans subclavatus* is treated in a similar way, as are also the varieties *C. fuscus*, *C. Weedi*, *C. Tolmiei*, &c. On the contrary several of the species of Baker are reduced to varieties, such as *C. Lyalli* to *C. elegans* var. *nanus*. The new species and those likely to be valuable decorative plants are *C. Porteri*, *C. Kennedyi*, *C. Greenei*, *C. Ghiesbreghtii*, *C. Palmeri*, and *C. Bonplandianus*.

Of new Lilies there are *L. Grayi*, with deep reddish orange flowers covered with purplish spots, from the summit of the Roan Mountain; *L. Parryi*, with pale yellow flowers having segments 3 in. long, found at the San Geronio Pass and San Bernardino County; and *L. maritimum*, which is in the way of *L. canadense*, with reddish orange flowers spotted below. It inhabits swamps from Marin and Humboldt Counties. What is known in gardens as *L. Washingtonianum* var. *purpureum* is raised to the rank of a species under the name of *L. rubescens*, and *L. Roezli* of Regel is placed as var. *angustifolium* (Kellogg) of *pardalinum*, which includes also *L. canadense* var. *Hartwegi* of Baker; *L. pardalinum Bourgaei* (Baker) is placed synonymous with *L. canadense*. Though the list of Brodiaeas does not contain any very remarkable addition it shows considerable alteration in the nomenclature. *Calliprora lutea* and *Hesperosecordum hyacinthinum* are placed here as Brodiaea *ixioides* and *B. laeta*. *B. volubilis* is altered to its original name *Stropholirion californicum*, and similarly *B. coccinea* to *Brevortia coccinea*. The long list of Alliums exhibits the alteration in names amongst the popular garden kinds. The beautiful *A. Murrayanum* and *A. Elwesi* are ranked as mere forms of *A. acuminatum*, and *A. Macnabianum* cannot be identified with any indigenous species. The monograph also embraces the Trillium family and several of the Asphodel tribe, including the elegant *Xerophyllum asphodeloides*, which by the way is changed to *X. setifolium*.
W. G.

PLATE CXC.V.

SEMI-DOUBLE VARIETIES OF IRIS KÄMPFERI.

THE Japanese Commissioners for the International Exhibition at Vienna in 1873 brought with them a select collection of plants useful as well as ornamental, and in doing this it appears that they had chosen the best productions to be found in Japanese nurseries—no easy matter, inasmuch as they are dispersed in great numbers, though small in size, all over Japan. One good variety of such and such a plant could only be found in one, and another in another nursery in a very different locality. Nowhere is a rich and good collection of new plants to be found in one place. It is to be regretted that no good botanist made that Vienna collection a special study; horticulturists did not pay much attention to it because the little Japanese garden in the exhibition ground did not contain many of the plants, the great bulk of which was stored up at M. D. Hooibrenk's nursery at Hietzing. Many of these treasures have therefore been lost to cultivation; amongst them, for instance, was the beautiful *Juncus effusus zebrinus*, the pith of the type of which furnishes the wicks for Japanese candles, and the bark that excellent tying material called Raffia, now so much in use in European gardens. There were also about 200 varieties of Lilies and quantities of Irises; conspicuous among the former were *Lilium Elisabethæ* (Hort.), which in point of colour surpasses *L. Parkmanni*; and among the Irises some varieties of *I. Kämpferi* were said to be gems of the finest description. In 1874 I bought these Irises without having seen their flowers, and brought them to Baden-Baden. They showed bloom in 1875, and amongst them were two blues of great substance and superb in outline, duplex, and brilliant in colour—one being a pale ultramarine, suffused with white, named *Mikado*, and the other pale indigo, called *Souvenir de Louis Van Houtte*. Two more of these are the varieties figured; the pale lavender one is called *Schöne Wienerin*, and the white with purplish-magenta suffusions *Imperatrix*. This latter is very thick petalled, and having used it as stock for hybridising purposes I have already obtained flowers of similar size possessing varied colours. The fertilised seed produced on an average 10 per cent. of plants worthy of further cultivation, but only one or two were of first rate merit. These Irises like a peaty, moist soil and a warm, sunny situation. I may mention that I have transferred my entire stock of these Irises to Messrs. Barr & Sugden, a firm which I venture to say is now in possession of the finest strain of *Iris Kämpferi* existing in Europe.
MAX LEICHTLIN.

GARDENING FOR THE WEEK.

Flower Garden.

Since my last notes under this heading were published, we have registered upwards of 4 in. of rain, and this, accompanied with cold winds, has so shattered the general stock of flowering plants that the bedding season may be said to be at an end even before it has well begun, and the sooner we can become reconciled to forego for this year the pleasure of well-furnished flower beds, the better. Our endeavour must now be to make amends for the lack of flowers by keeping the garden generally in the neatest possible condition; walks must be rolled frequently, edgings cut at least once a fortnight, and lawns kept short and trim, and these, combined with the magnificent foliage and appearance of deciduous trees, consequent on the wet season, will be no mean substitute for the lack of a brilliant parterre. Though this is the season in which to propagate Pelargoniums, obviously, for want of cuttings, this cannot be done, and provision should therefore be made for wintering the old plants, and propagating in the spring. Other cuttings can be had in limited quantities, and a hotbed should be made upon which to strike them. A few store pots of cuttings of each of the following should be got in as soon as possible now: *Colens*, *Iresines*, *Alternantheras*, *Heliotropes*, *Verbenas*, *Petunias*, *Ageratums*, *Lobelias*, and all plants of a similar character. *Violas* and *Calceolarias* need not yet be propagated, as they strike well in cold frames, if put in any time before the middle of October. Sub-tropical plants, like the general stock of bedding plants, are most unsatisfactory. Castor Oil Plants are amongst those that have made the best growth, and now require stakes, as do also *Eucalypti*, *Wigandias*, and the taller-growing *Solanums*. Keep the surface soil of the beds well stirred, and this will help in some measure to advance growth. What with weeds and decayed flowers, mixed herbaceous borders present a very miserable appearance, and till the weather becomes settled such a state of matters must, of necessity, continue, but the first opportunity should be taken to render them more attractive. Stake *Phloxes*, *Solidago*, *Potentillas*,

L.

Chrysanthemums, &c., and any vacant spots may be utilised for sowing a few hardy annuals, such as *Limnanthes Douglasi*, *Collinsia bicolor*, *Saponaria calabrica*, *Silene pendula*, *Nemophila atomaria*, and *Candytufts*, all of which are perfectly hardy, and will flower very early in the spring, and at a time when other flowers are scarce.—W. W.

Auriculas.—It may be necessary just to say a few words about the autumn-blooming of these. Many of our finest plants of George Lightbody, Lancashire Hero, Beeston's Apollo, &c., are throwing up trusses, and we have no alternative but to pinch the flower-buds off the stem as soon as they can be grasped with the fingers. A new centre will be formed to the plant, but it is not at all likely that the truss produced next spring will be so good as it would have been had there been no autumn truss. Some growers have stated that the liability to bloom in autumn is diminished if the plants are repotted in July or early in August, a statement which my experience does not confirm. This year I had a number repotted late, and there is more autumn bloom amongst these than amongst such as were early potted. The only way to have as little autumn bloom as possible is to keep the plants cool. Place them behind a north wall and do not allow the glass lights to be over them when it does not rain. About sorts difficult to grow a few remarks may now be usefully made. Such kinds as Booth's Freedom, Page's Champion, and a few others are very difficult to manage. The Rev. F. D. Horner with his intense zeal has cultivated them successfully, and Mr. John F. D. Llewellyn, of Ynisgerwn, has been successful in growing Freedom under a system which, as far as I know, has not been tried before; no doubt both these growers will tell us all about the mode of culture, for the true florist keeps no secrets from his fellow-cultivators.

Carnations and Picotees.—It was stated last week that layering would not be done until the end of September, but it ought to be finished by the end of August. We began our layering in earnest and have now finished it. The work was done much more quickly through the use of a new knife sent from Sheffield by Mr. Simonite. We used to cut the stem upward through a joint, but on the new system we thrust the knife through the joint and cut downward. The blade of the knife is very thin, sharp on both sides, and pointed—a real boon to growers of Carnations. Let all the layering be done as speedily as possible, whether the plants have done blooming or not.

Dahlias.—The few warm days which we had about the middle of August greatly invigorated the growth, and now we had abundance of good flowers; but the striking effect which a bed of Dahlias possesses, when seen either close at hand or at a distance, has been sadly marred by the dashing rains which we have had. The plants require constant attention in the way of thinning-out superfluous growths and flowers, and tying up the remaining growths to sticks placed round the main support at the centre of the plants. Earwigs, not liking so much wet as we have had, have not troubled us much, but slugs seem to take their place; these latter must be searched for at night with a bull's-eye lamp and destroyed.

Gladioli.—I wrote somewhat despondingly concerning these a few weeks ago, and they have not improved since. They are now quite done for the season, no spikes of flowers showing themselves. The Gladiolus likes a hot, dry season and, above all, a dry autumn. I am certain that our ordinary English seasons will not do for the finest hybrids of *Gandavensis*; but a fine field is open for the hybridiser who will take the best of these and cross them with a more hardy species. I well remember the late Mr. John Standish telling me, when I was exhibiting scores of fine healthy spikes and growing them by the thousand, "that I would not do so long, that they would degenerate," and they did. In order to keep up a healthy stock seedlings must be raised, and fresh roots must annually be introduced.

Phloxes in Pots.—Messrs. Laing & Co. have shown us the utility of these fine flowers for pot culture by grouping them by themselves. The other day they also had a group of plants at Penge with Phloxes intermixed, and there the effect was much more striking than at South Kensington. Everybody should grow a few for their greenhouses or conservatories in August and September; as they go out of bloom let the stems be cut off and the pots placed out-of-doors. Do not let them suffer from want of water.

Pentstemons.—These are very gay just now, and they do not require more attention than seeing that the flowering stems are tied to their supports.—J. DOUGLAS.

Greenhouse.

Where any inside painting has to be done there should be no delay, in order that the houses may be fit for the reception of the plants now placed out-of-doors. Before housing them the glass should also

be well washed, and where no painting is required the woodwork also, as well as the stages; and any repairs needed should be attended to. Where there are any defects in or insufficiency of piping, it can likewise be best set to rights at this season.

Camellias.—Any of the latest flowered plants which have been necessarily late in making their growth will be now about setting their buds, and in the case of those that want more root room, they should at once be placed in either larger pots or tubs, as by being moved now their flowering during the coming spring will be little affected, and through the autumn they will have time to root into the new soil, which will evidently place them in a much better position for making growth next year than if the potting were deferred until after they had bloomed in the spring, when their roots are in the tenderest condition. Those who have not potted these plants in this stage of their growth will if they give it a trial, I feel convinced, find it the best. Camellias are subjects that require little training, and should not be submitted to the twisting and interlacing sometimes practised, and when they have got into a thin straggling state heading down is often the best remedy. But yet with plants in such a condition any strong branches may with advantage be tied in to a moderate extent when the work is done, so as not to give them a formal appearance; but branches so treated should not be bent down too much, or they generally cease to make further growth from the points, simply pushing out young shoots at the point where bent.

Greenhouse Rhododendrons.—Those who possess a good selection of these, especially such as have been raised from crosses of *R. javanicum*, will find them extremely useful for conservatory decoration during the summer months when *Azaleas* and other kindred plants are out of flower. Where wanted they can be had in bloom earlier in the season, but where there is a sufficient number at command, by keeping them cool enough so as to induce late growth, and after their flowers are set by using no more heat through the winter than requisite to keep them from injury, they will continue on blooming until the end of August. The character of the flowers is such, with their many shades of colour from white, orange, yellow, and red to the deepest crimson, together with their capability of lasting long in a cut state, as to make such plants deserving of more general cultivation than they receive. Where there is a large conservatory necessitating the use of considerable numbers of tall-growing subjects with climbers overhead that tend to darken the lower portion where plants have to stand, there are few things that will be found so serviceable as these Rhododendrons, as during the time they occupy a place in such a structure they will not suffer as many subjects do. Plants of these Rhododendrons that flowered early will have made growth and set their blooms, and may be now for some time treated so as to discourage further extension, though there is a peculiarity about several of the varieties, viz., their making growth and setting buds which remain dormant whilst a second growth and more buds are formed that in the spring flower in succession. Those that have bloomed later must be encouraged to make growth and get their wood and flower-buds matured before the season is too far advanced. In addition to their other merits their remarkably easy growth being little susceptible to injury from extremes of a dry or wet condition of the roots that would kill or injure the majority of other plants, and their little liability to the attacks of insects, are all in their favour. Some of the finest examples of these Rhododendrons I have ever met with were in full flower up to the middle of the present month, which will give some idea of their usefulness for the purpose I have mentioned. The fragrance which some of the varieties possess is another matter worth taking into account.

Oranges.—Where these, or any other of the Citrus family, are turned out-of-doors in the summer after their growth is made, it is doubtful whether they are ever benefited by such exposure, and in cold, drenching seasons like the present, especially if the plants are deficient of roots proportionate to the size of the pots or tubs they occupy, they are almost certain to be injured by it, and even with specimens in the best of health I should advise their at once being got under cover, for although they often bear a good deal of indifferent treatment and seldom die suddenly, it is a very common occurrence to see them in a dwindling state, to which death would be preferable. The hard usage they frequently stand is much more an evidence of their ability to struggle under adverse conditions than of their liking such treatment. They come from latitudes too warm to be benefited by exposure to the fluctuations of our fitful climate. Previous to taking them in, it is well to give them a thorough cleaning, especially where affected with scale, as at this time when such as have been thus out-of-doors will have made early growth, and had their wood and leaves hardened up, they are much less likely to have their foliage injured by the sponging and brushing necessary to remove the insects. The removal of the dirt deposited on the leaves by brown scale is essential to keeping them in a healthy condition.

Humea elegans, though generally looked upon as a subject more suitable for planting out in summer than for growing in pots, is nevertheless not surpassed for standing, when fully developed, in conservatories, porches, verandahs, or anywhere where elegant-growing plants are wanted. One thing in its favour often overlooked is that in addition to its distinct habit, its colour is such as to admit of its being placed in close proximity to any other species of plant; but to have it in the condition it ought to be, although its culture is extremely simple, it must never be neglected from its first emerging from the seed-pan up to the time when its inflorescence is fully developed, otherwise the plants will either become stunted if their wants are not supplied in their younger stages, or they will lose a portion of their leaves if not well sustained later on. Plants raised from seed this spring, and moved from the seed-pan into small pots, will soon need another shift; if they have been well attended to they will be large enough now to move into 6-in. pots in which to remain through the winter. Good ordinary loam thoroughly enriched and made porous is all that is required. A cold frame placed on a bed of damp coal ashes is a much better position for them than in houses on dry stages, which tend to the increase of red spider, to which the plant is very subject. Water, air, and frequent examinations to see that the plants are free from green fly and red spider is simply all the attention they require.

Cinerarias.—The first batch of these raised from seed, so useful for flowering about the close of the year when the blue colour they afford is scarcely attainable in anything else, must now receive every attention to have them in blooming condition at the time needed; the cool, damp, dull summer has been much more favourable to their growth than it has to the generality of plants, and in several cases that have come under my notice they are unusually big and strong, and to support the extra large foliage they have upon them it will be necessary to give them pots an inch or so larger than ordinary, or to supply the deficiency by more manure water than usual, for if they suffer through insufficient nutriment the lower leaves are sure to go, the certain result of which is that the heads of flower are never more than half the size they otherwise would attain. Should the weather come hot and dry during the next month it will still be necessary to shade them slightly from the sun during the middle of the day. The later sown stock, or plants raised from suckers where the old stools have been planted out, should be potted off and encouraged to make growth so that they can be transferred to their blooming pots before the autumn is too far advanced, for unless they get their roots fairly established in the soil before winter they can never be expected to do well.

Primulas.—Plants from the earliest sowings of these, if not already in their flowering pots, should at once be transferred thereto, using every means to get them on in size and strength. Shallow frames where they can be elevated so as to almost touch the glass will still be the best place for them until considerably later on, and if the frames in which they are grown are placed so as to be under the full influence of the sun, continue to shade them slightly for a few hours in the middle of the day. The object with these plants should be to get them as stout and short in the leaf-stalks as possible, as when so grown they are much less liable to damp; I have found nothing more conducive to this stout condition than for the next month taking the lights off them altogether during the nights when there is no appearance of heavy rain. Plants from later sowings intended to flower later in the spring and yet in small pots should have every attention with a view to getting them in condition for moving into those they are to bloom in a few weeks hence.

Chrysanthemums should now be securely staked, for if this be neglected, as their shoots get heavier, they are in danger of being broken. Whether the pots be plunged or not, they should be turned round every ten days, to prevent rooting through the pots, for if this is not attended to, the roots that find their way through the bottoms of the pots naturally get the strongest, leaving those confined within less active, and whatever progress is made in this direction has afterwards to be sacrificed. They will be benefited by manure-water regularly, still keeping on syringing overhead on the evenings of warm days, which will generally be found sufficient to ward off the attacks of aphides. A good look-out must be kept for the little grubs that prey upon the leaves, burrowing between the upper and under cuticle like the Celery fly, and which, if left uninterfered with, will in a few days destroy a considerable amount of foliage.

Tropæolums.—The different varieties of these belonging to the Lobbianum section, so useful for flowering through the winter with a little warmth, are better when the plants are kept out-of-doors during the summer time, and loosely trained to a few sticks inserted in the pots. By this means stout, vigorous, pyramidal specimens can be had in much better condition for producing flowers in winter than when kept on growing under glass during the summer. Plants that have been treated as recommended, and, if in compara-

tively small pots, have been assisted with a little manure-water, will be in a state to do good service through the winter, if subjected to a little dry warmth in a good light house or pit; but they are very impatient of a low temperature, and they will not be safe out-of-doors in the nights beyond the middle of the coming month.

Tree Carnations.—Give these the advantage of a good light position where they will be exposed to all the air and sun they can get. In the case of old plants that after blooming were shortened back, shaken out, and repotted, some manure-water from time to time will greatly assist them. Use sufficient sticks to keep their shoots supported in an erect position, but not too closely drawn together.

Salvias.—The kinds intended for autumn flowering, as well as those to succeed them in winter and spring, should by this time have their pots tolerably filled with roots, and from their naturally strong vigorous habit, they with difficulty retain their lower leaves, or keep in a healthy green colour, unless they are assisted with liquid manure; but in this it is necessary to proceed with caution and not to apply it so strong or so often as to excite an undue amount of growth, as after this time it is better to treat the plants with a view to maturing the growth which they have already made than encourage its extension further.—T. BAINES.

Hardy Fruit.

Although in this district Pears are tolerably plentiful, they are so small, and the season so advanced, with as yet no signs of real summer, that it is a debatable question as to whether they will ripen at all. Certainly the latest varieties will not, but the early kinds may, though even these seem hidebound and do not swell kindly. Under the circumstances it will be advisable to at once pull off all fruit not likely to ripen, in order to give the trees a greater chance of bearing next year, when it is to be hoped that the weather will be more propitious. Early varieties that may ripen should have all the help that can be given them, such as fully exposing the fruit to atmospheric influences by cutting, or pinching off any shoots that intercept the full play of light on it. Such operations are also necessary in order to ensure the full maturity of next year's fruit-bearing wood, for on this also depend our hopes for another year, and these, unfortunately, are not very bright, seeing that wood growth is more vigorous than usual, and no sunshine to consolidate and ripen it. To a certain extent the foregoing remarks concerning Pears are applicable to Peaches. On some of the late kinds the fruit is still so puny that it is impossible for it to ripen, and it might, therefore, be sacrificed at once to afford a better prospect for next year. The wood on all the trees should now be kept well thinned out, and fresh growth, which is more profuse than usual, should be constantly stopped back. Apricots are making extra fine growths, and advantage should be taken of this, especially in the case of all old trees with ugly spurs, to lay in all the best shoots to replace these spurs at the winter pruning. The dying off of the branches, a disease peculiar to the Apricot, has been very prevalent this season. I know of no real preventive, but believe a severe check or strain of any kind tends to induce it; and my theory regarding its prevalence this year is that the severe and long-continued frost and water-logged state of the ground are at the bottom of the evil. In every garden where Apricots are valued there should always be a relay of young trees on hand to take the place of any that thus succumb. Early Orange Apricot, though generally worthless, is this year large and passable in flavour, but, taking all points, Moor Park is the best that can be grown, and a sure fruiter. The rain is causing some of the fruit to crack before it is quite ripe, and therefore it should be gathered before it reaches that stage, and if placed in a warm Vinery or greenhouse, it will there ripen off perfectly. All early kinds of Apples and Pears are improved in flavour, and keep longer if gathered a few days prior to full maturity; some kinds are now ready and should be examined with that intent. Morello Cherries should now all be gathered, the trees thoroughly cleared of vermin, and the new shoots of the current year nailed or tied in. Established Strawberry plantations should have all the runners cut off, and the ground between the rows "pointed" over, and afterwards thickly mulched with good manure. Newly-planted plots should also have the runners persistently pinched off. The plantation made with the earliest forced plants may be expected to fruit freely this autumn, and for these a layer of clean straw to keep the fruit clean should now be applied. The ligatures of grafts ought now to be removed, and the shoots produced by the stocks should be kept rubbed off. In some instances, such as where the union has not been properly established, a temporary tie may be requisite, in order to prevent injury from wind-waving.—W. W.

Extracts from my Diary—September 1 to 6.

FLOWERS.—Shifting Cyclamen bulbs into flowering pots. Potting Cinerarias out of 3-in. pots into 5-in. pots, in which they are to flower. Putting in cuttings of Violas in border for spring bedding.

Re-arranging plant houses. Putting in cuttings of *Viola* under north wall for spring bedding. Cutting *Lavender* for distilling. Putting in cuttings of *Pelargoniums* and *Fuchsias* for winter flowering. Tying shoots of *Maréchal Niel* Rose in cold house and loosening buds on *Briers*. Putting in cuttings of *Heliotrope* and *Ageratum* for stock.

FRUIT.—Gathering *Williams's Bon Chrétien* Pears and *Keswick Codlin* Apples. Cutting out wood from *Figs* in order to give the fruit more light. Gathering all ripe Apples and pulling runners off *Strawberries* growing for forcing. Tying and stopping *Melons* for late use. Gathering all ripe *Early Beatrice* and *Royal George* Peaches, *Victoria Nectarines*, *Cellini Pippin* Apples, and *Victoria* and *Prince of Wales* Plums for preserving. Gathering all ripe Peaches and *Beurré d'Amanlis* Pears. Cutting a few berries out of late *Grapes* where too thick. Tying up shoulders of *Trebbiano* *Grapes*. Gathering *Washington* Plums. Removing all runners from *Strawberries* for forcing, and giving them a little more room where crowded to admit air and light.

VEGETABLES.—Hoeing ground between growing crops of *Cabbages*, *Cauliflowers*, and *Lettuces*. Getting old bed out of *Cucumber* house and turning and mixing manure and leaves for next bed for winter *Cucumbers*. Tying, training, and stopping *Tomatoes*. Planting out *Bath Cos* *Lettuces* and more *Endive* for winter use. Getting in hotbed in *Cucumber* house for winter *Cucumbers*. Clearing up walks, and sowing *Mustard* and *Cress*. Mixing loam and leaf-mould in which to plant *Cucumbers*. Pulling up *Carrots* that are running to seed. Harvesting *Onions* and storing them on stages in cold houses to dry. Storing *Regent* *Potatoes* and covering them with straw. Gathering *Tomatoes*. Earthing up *Celery*. Clearing *Peas* off ground and manuring it for winter digging. Digging *Couch* *Grass* out of *Asparagus* beds and giving them a good coat of ashes and rotten manure preparatory to trenching. Cutting out useless growths from *Tomatoes* and also a few leaves to ensure the fruit ripening. Planting the following sorts of *Cucumbers* for winter, viz., *Hedser Prolific*, *Telegraph*, and *Duke of Connaught*. Spawning first *Mushroom* bed.—R. GILBERT, *Burghley*.

THE FRUIT GARDEN.

SUPPLEMENTARY FRUIT REPORTS.

Wierton House, near Maidstone.—*Strawberries* in the garden here have been a very heavy crop, the best kinds being *Keen's Seedlings*, *Princess Alice*, *Wonderful*, *Vicomtesse Hélicart de Thury*, *Trollope's Victoria*, and *Elton Pine*. *Raspberries* are also a heavy crop. *Red* and *White Currants* are very plentiful; *Black* rather thin. Of *Gooseberries* we have a heavy crop with the exception of the *Yellow Rough*, which is nearly a failure; some of the large *Lancashire* sorts have produced heavy crops, but the foliage of all kinds has been much injured by mildew and insects. Indeed, it is falling off fast, and in a few days the trees will be bare. The fruit, being thus exposed, has commenced to shrivel. *Peaches* and *Nectarines* are a light crop, and the trees are unhealthy. Of *Apricots* we have none. Most kinds of *Plums* are light, and the fruit is still dropping off and the trees gumming. *Cherries* are a very light crop and spotted. *Hardy Grapes* must be a failure; they are now shedding their bloom. *Figs* promised to be a heavy crop, but most of them have fallen off, and they still continue to do so. *Pears* are a light crop and the fruit is still falling. *Apples* the same; *Winter Hawthornden* and *Cellini* are producing the best crops. In the orchard the best crops are *Graham's Pile Russet* and *Loddington Seedling*, a kind which must become a general favourite for market purposes. Other sorts are bearing light crops, and the ground is strewn with fruit. In plantations, where fruit is grown for market, *Gooseberries* and *Currants* have been plentiful in some cases, in others a light crop. *Plums* of all kinds, with the exception of *Damsons*, are a thin crop. *Cherries* very light. *Nuts* promised to be good, but they are suffering from too much wet. *Apples* of most kinds are light crops. Altogether the fruit crop will be very deficient in quantity. The soil here is a light sharp loam on the *Kentish Ragstone*, sheltered by timber trees and woodlands.—W. DIVERS.

High Grove, Pinner.—The fruit crops in this neighbourhood are in most cases much below the average. *Gooseberries* and *Red* and *Black Currants* rotted on the trees. Of *Strawberries* we had good crops, but they also rotted from want of sunshine. *Raspberries* have in most cases been good this season but very watery and deficient in flavour. *Peaches* and *Apricots* are almost a failure, and the trees are in a most deplorable state from blight. In orchards *Plums* are a failure in this neighbourhood; also the *Damson* crop,

and *Apples* in most places are quite stripped of their foliage by blight. *Court Pendu Plat* is one of the best varieties for garden culture, as it flowers much later than any other, and is always a sure cropper; it does for cooking, and is a most excellent late dessert middle-sized *Apple*. The *Wellington* is quite a failure hereabouts this season. It is usually one of the best *Apples* which we have and one on which we most depend. It is a good market *Apple*, and therefore it has been largely planted in this neighbourhood. *Pears* are in most cases fair crops, but so late that I am afraid they will not come to maturity. This district is a very late one in cold, wet seasons, its subsoil being *London clay*, and in many cases badly drained.—G. BRUSH.

The Deepdene, Dorking.—The fruit crop in this neighbourhood is in general under the average. *Apples*, with the exception of *Lord Suffield*, *Keswick Codlin*, *Dutch Codlin*, and *Hawthornden*, are very thin; those mentioned are bearing a very full crop. I have also seen some well laden trees of *Tower of Glamis* in this district. *Pears* of all sorts are a heavy crop except *Marie Louise*, which are thin this year. *Apricots* a fair crop. *Peaches* moderate but very late, trees healthy. Of *Plums* some varieties have borne well, others thin; on *Rivers's Early Prolific*, *Blue Perdrigon*, and *Prince of Wales* there are heavy crops, others moderate. *Strawberries* and small fruits have been plentiful and good. *Figs* are a heavy crop, but they may not ripen. *Cob Nuts* are very plentiful, but *Walnuts* are scarce. *Cherries*, with the exception of a few *Black Tartarian* and *Morellos*, are a total failure.—JOHN BURNETT.

Wilton, Salisbury.—Of *Apples* we have a bad crop; trees and fruit much blighted. *Apricots*, fair crop; trees protected in spring by three thicknesses of ordinary 1-in. mesh netting. *Cherries* good on walls protected by nets; none on pyramids and bush trees protected with fir branches. Of *Currants* we have a fair crop. *Figs* moderate, trees protected with nets in spring. *Gooseberries* moderate. *Mulberries* a fair crop. *Nectarines* and *Peaches*, fair crops; trees protected by canvas blinds on rollers; leaves much blistered in spring. Of *Nuts* and *Filberts* we have good crops. *Pears* moderate; trees and fruit much blighted. *Plums* moderate on east wall, protected with nets; none on pyramid and bush trees. *Raspberries* are a fair crop. *Strawberries* abundant. *Walnuts* a bad crop. Owing to the excessive amount of rain, and the long continuance of cloudy weather, fruit trees of all kinds present a yellow and sickly appearance. A large percentage of the fruit is blighted, and dropping off the trees. Unless fine weather sets in shortly I fear the young wood will scarcely have time or heat sufficient to ripen. Since January, 27 in. of rain has fallen here, and with the continued low temperature and absence of sun this has been the most unfavourable year as far as gardens are concerned that I have known.—T. CHALLIS.

Wortley Hall, Sheffield.—Everything on the farm and in the garden in this district is a month or six weeks late. *Wheat* and *Barley* are only in flower or coming into flower, and in the garden we are still gathering the *Black Prince Strawberry*, which is generally over by July. *Apples*, *Pears*, and *Plums* are a poor crop, and not likely to ripen perfectly. *Cherries* are good, and all small fruits are most abundant, *Strawberries* and *Gooseberries* particularly; we have seldom had such a crop, though many *Strawberries* have rotted. Under glass crops have done better than the character of the past year would lead one to expect. *Grapes* are good and well finished; late crops and *Muscats* promise well, and are colouring as well as ever we remember them to have done. *Peaches* are plentiful, and also *Figs*. *Melons* have been fine and crops good.—J. SIMPSON.

Huntroyde, Burnley.—Small fruits, such as *Gooseberries*, *Currants*, *Raspberries*, &c., are abundant here, and the fruit fine. *Strawberries*, though a good crop, were inferior in flavour, and a great part rotted on the ground. Of *Apples* we have good crops on garden standards; in orchards they are a failure. Being exposed to cold east winds the young wood did not make a fair start ere it was destroyed by caterpillar, which also destroyed the fruit just at the time when it was setting. *Pears* on south walls are a fair crop, but I am afraid none of them, not even the *Jargonelle*, will reach their average size; they are now small and look starved, though the trees are making very fine growths. *Plums* are good on south walls, but moderate on east; none upon north-west aspects. *Cherries* are good, especially the *Morello*. *Apricots* and *Peaches* are not grown outside here, but we have good crops of them in a glass case; the fruit is, however, very late, and does not look like ripening even there. In our early houses the crops have been good, but not so good in quality as usual. *Nuts* are abundant, but not filling well. All kitchen garden crops are very late, and less productive than usual. The *Potato* crop is inferior and showing signs of disease. Every crop is at least a month later this year than usual, and some will not do any good at all.—H. LINDSAY.

MELONS IN 1879.

ALTHOUGH this has by no means been a favourable season for the production of high flavour in Melons, owing to the small amount of sunshine which we have had, a few remarks on varieties that have proved themselves to be well worth growing may be interesting. Melons form no small help in a season like the present to replace fruits that are either entire failures, or so late in coming to perfection out-of-doors as to be of little service. Our earliest crops of Melons grown in pots on the back shelves of Cucumber houses and Pine pits included Cox's Golden Gem, a very beautiful, medium-sized Melon, of a bright golden colour, finely netted, and of good quality; Eastnor Castle Green Flesh, always good, if true, rather a tender-skinned variety, liable to bruise, if roughly used, in travelling; Heckfield Hybrid, a good, well-known sort growing to a good useful dessert size; Gilbert's Victory of Bath, a deliciously flavoured green flesh kind, and a heavy cropper; Queen Emma, a good variety, flesh almost white, very melting and juicy, but rather thin-skinned and tender.

For late use we have now ripening, in addition to the above, good crops of Dell's New Hybrid, a fine-looking Melon, carrying a heavy crop, and amongst old sorts Sheriff of Haddington, a good cropper, and the fruit of serviceable size. For pits or frames where but little heat is available Monro's Little Heath is still one of the best, and if afforded good treatment under glass, with aid from artificial heat, it grows to a large size, and is excellent in flavour. There are many other equally good sorts, but in the case of a fruit so easily hybridised as the Melon, it is difficult to keep them good and true; in fact, the only way to keep any really good sort distinct is to grow that alone. There is little gained by multiplying varieties, as even the best are greatly dependent on the manner in which they are cultivated and the time at which they are cut, to catch them in their highest state of excellence. Although we grow Melons in pots for our earliest crop, I greatly prefer planting them out in a good ridge of soil. The top spit of loam is what we rely on, chopped up moderately fine, and packed firmly; in this they make vigorous growth, and when they have reached the desired height I pinch out the leading shoot, and on the laterals fruit will show in abundance; enough for a crop should, as nearly as possible, be set at the same time, for if one or two fruits set and swell in advance of the rest they will rob the latter of all support, and they will turn yellow and drop off. With a good bed of soil and room for the foliage to expand, a Melon plant will ordinarily perfect from four to six fine fruits fit for any dessert table.

J. GROOM.

DYING OFF OF APRICOT BRANCHES.

THIS malady is, according to my opinion, ascribed to causes that have little or nothing to do with it, that is, so far as bringing it about is concerned. The trees, like everything else that has been laid prostrate or weakened by disease, are unable to bear up when the strain comes, and soon show signs of distress. This occurs when they are taxed with a heavy crop of fruit, which their enfeebled health prevents them from carrying, or the same thing occurs if the weather is excessively hot and dry, as then there is more evaporation going on through the leaves than can be maintained from below. This apparent failure on the part of the roots is owing to the greater portion of the sap-vessels in the bark being injured by frost or cold in the spring, which not only impedes the circulation at the time, but causes gumming through extravasation, or a thickening of the fluid, which, instead of effecting its escape, should have gone to build up and form fresh layers of wood. After mild winters and genial springs gumming is never seen to any extent; but let any one go where he will in seasons like the present, trees are found in a deplorable plight, and no wonder, as from their tender nature and the early period at which they are on the move, the whole system must perforce get a chill that would of itself bring about constitutional derangement, although its effects would not be immediately apparent. From close observation, however, I am persuaded that this is when the mischief is done, and once the sap vessels are ruptured, the whole constitution of the plant is disorganised and thrown out of gear. Where trees escape frost, branch dying is almost a thing unknown, a remarkable instance of which I could have pointed to some years back, where an Apricot tree was growing on the south end of a house, under overhanging eaves, so as to get a good deal of warmth from the kitchen chimney and other flues that passed up the inside of the brickwork. This tree never failed to bear a heavy crop, and I do not remember to have ever seen a dead spur or branch in it, although at the time, judging from its stem, it must have been of great age, as it was very large, and had a top that covered at least 200 square feet. The losses amongst Apricots will be great this year, and it will be found that the colder the district, or the more exposed the position, the more they have suffered, not only in loss of fruit, but of limb. Although well protected by means of copings, fish nets, and evergreen branches, ours are reduced to about half the

size they were, whole faggots having been cut out of them, and barrow-loads of spurs wheeled away; but as this was done early, I am glad to say they have all broken well again, and are fast filling the gaps. Half measures are no use, the knife is the only remedy, and the sooner the diseased parts are got rid of the better, for they only carry the decay further, or prevent young growth forming in positions where it would be available to take the place of injured branches. If left, the affected branches are sure to go, and the first loss is generally the least sacrifice.

S. D.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Stone's Apple, or Loddington Seedling.—It is singular how some really first-class kinds of fruit remain only locally known for years, while other greatly inferior kinds in a short time overrun the country, and, in the majority of cases, as quickly disappear. Stone's Apple is not a new kind, for the produce of trees of this variety growing in the parish of Loddington, on a fruit farm recently occupied by Mr. Stone, was so highly prized and sought after in London markets, that for want of another name it was called Stone's Apple, or Loddington Seedling. It was, I believe, shown in London, and granted a certificate in 1877; but the best of all its certificates would be for any intending Apple planters to come and have a look into the orchards in this neighbourhood, when, although the season is called a failure as regards Apples, this particular variety will be found to be invariably carrying a large crop of fruit superior in every respect to that of the Keswick Codlin. Stone's Apple is much larger, and yellowish-green in colour, with a pale red flush. It is of very stiff growth, and requires scarcely any pruning; the foliage is large, and the whole energy of the trees seems concentrated on the formation of flower buds. I may mention that in this locality rows of large orchard trees have been headed back and re-grafted with this variety, and thus treated they speedily form fine heads. Although generally grown in orchards as a standard, its habit of growth and bearing eminently fit it for a dwarf or bush tree, and I feel sure that, when once it becomes well known, it will supersede many of the existing kinds. It is one of the earliest of Apples, being now (middle of August) the largest fit for kitchen use, and it would keep in good condition until November. It is the very ideal of a market or kitchen garden Apple, as it fills the basket quickly, and in this exceptional season, when the remnant of a crop is not swelling at all kindly, at least half of the sorts being deformed, and looking stunted and mis-shapen, and dropping off prematurely, this variety stands out in bold relief as the one bright spot in our Apple orchards. I see no reason why it should not be equally satisfactory in other localities as it is here. As regards the season, we have more fruit trees without a fruit on them than we have carrying a crop, yet those who are the least versed in pomology look upon the Stone's Apple as such a certain cropper, that they think it not at all singular that all the trees of that variety should be carrying a good crop while others are bare. I would strongly recommend any one wishing to give this fine variety a trial, in addition to planting young trees of it, to try the Kentish plan of grafting a vigorous but unfruitful tree of some other sort with this kind. It is easier to do this than to root-prune.—J. G., *Linton*.

Management of Plantations of Black Currants.—Select a spot with a cool moist bottom, wheel on to it a liberal dressing of manure—and a somewhat wide definition may be given to this term, as everything calculated to improve or enrich the land will be useful. It is well to prepare the land thoroughly before planting, as, on suitable land, Black Currants may occupy it profitably many years. The soil should be deeply worked, and the manure well incorporated. With other kinds of bush fruits it is necessary to mount them on single stems, and prevent the formation of suckers; but with Black Currants this rule need not be so rigidly enforced. For a plantation of so permanent a character, 6 ft. square is not too much space for each bush to occupy, especially if they are permitted by the formation of suckers to become virtually what nurserymen call stools. There may be objections to these kinds of bushes, but I know they are exceedingly fruitful, and the fruit is as fine as that produced by plants confined to a single stem; and the way the bushes renew themselves from the base seems to add to their vigour. But on this matter people may hold different opinions, without saying or even supposing that those who differ from them are wrong. I have seen amazing crops of fruit grown on those old bushes that appear to be a cluster of stems annually renewable from the base. The plantation will be best in an open situation, although fairly good results are obtained in partially shaded positions. Early in May mulch the ground between and around the bushes thickly with littery manure. The first season after planting cut well back, to get a strong base. Afterwards thin out, but do not shorten; and as years pass, and the bushes become large, cut out a number of the old shoots down to the

bottom annually to make room for new growths, as it is these latter that bear the best and finest fruit. When the plantation settles down into a free-bearing condition, only surface culture with fork and hoe will be required. Black Currants should be gathered as soon as ripe, as the large berries soon drop when fully ripe.—E. H.

FRUIT NETS.

In answer to Mr. Groom's enquiry, allow me to say that he would probably find linseed oil (raw or boiled) a good preservative of fruit nets. I have a hemp fly-line which has been in use at least thirty years, perfectly sound and good, which was when new steeped in linseed oil, and then stretched and dried in the sun. I have also a landing net similarly treated, which has been in use some years. The net should lie in oil, or in an oily state, for a day or so, and should then be wrung out, so as to free it as much as possible from the oil; afterwards it should be stretched out to dry in the sun for several days. I have, however, adopted a net covering which is self-preserving to a great extent. I fix the net on frames, 6 ft. by 4 ft.,

Net-frame.

made of good deals, 4 in. by 1/2 in. A galvanised wire rod (16th of an inch) is run through the meshes to attach the net to the frame all round. The ends of these rods are turned into the wood to prevent them from slipping, and then they are fixed to the frame, at intervals of about 12 in., by thin wire loops put through a hole made with a sprig bit, and clenched on the under side. The frames thus made can be fixed over a Strawberry bed by resting one end on a thin pole, supported by forked sticks up the centre of the bed, thus—

or laid flat on narrow boards supported on edge round the bed and up the middle by pegs, thus—

Such frames are also useful for covering wall trees in the spring and Currant trees when the Strawberries are over. They take up little room when put away, and cannot be thrown aside damp, probably in a heap, when done with, as is the fate of a good deal of netting; and when wanted again found to be rotten. Such frames can, of course, be made to any size; but dimensions which will render them available fixed in any way would be best. V.

The Hailstorm Relief Fund for 1879.—A public meeting was held at the Greyhound Hotel, Richmond, on Monday evening, August 25, for the purpose of raising a fund for the relief of sufferers through the recent hailstorm. Mr. John Fraser, Lea Bridge Road Nursery, was in the chair, and the meeting was numerously attended by representatives from all the neighbourhoods affected by the storm. Statements having been laid before the meeting showing the extent of the damage sustained, and the urgent need that exists for raising a relief fund, the following resolutions were unanimously passed: "That this meeting is of opinion that, in consequence of the enormous damage caused by the destructive hailstorm of August 3rd, in Richmond, Twickenham, Teddington, Brentford, Isleworth, Ealing, Kew, Kingston, Surbiton, and their neighbourhoods, there is great and urgent need for the formation of a substantial relief fund to be distributed among such market gardeners, nurserymen, and florists as have been large losers by the storm, and who have little or no means to repair their grievous losses." "That a relief committee, with power to add to their number, be formed forthwith, and that such committee be empowered and requested to take the necessary steps towards making a widespread appeal for funds, to examine

and assess all cases for assistance, and to distribute the funds accordingly. During the discussion which ensued on the consideration of these resolutions, a great desire was expressed that all merely local relief funds should be merged into a general relief fund, with its head-quarters at Richmond. The Rev. G. W. Hawtayne, vicar of Whitton, handed over to the central fund the proceeds of a collection at Whitton Church, made for the sufferers; and the Rev. H. R. Limpus, Vicar of Twickenham, promised the proceeds of an offertory at Twickenham Church, and said he would advocate the claims of the fund from his pulpit. He hoped other clergymen in the affected districts would adopt a similar course. A large and influential committee was appointed: Mr. W. Pennyfeather, Manager of the London & County Bank, Richmond, was elected Hon. Treasurer; and Mr. Richard Dean, Ranelagh Road, Ealing, and Mr. Edward King, Richmond and Twickenham Times Office, King Street, Richmond, Hon. Secretaries. The sum of £350 was announced as having been already paid or promised to the relief fund. Contributions can also be paid to the credit of the fund at the London & South-western Bank, Ealing.

TREES, SHRUBS, AND WOODLANDS.

WOODLAND WORK FOR SEPTEMBER.

DURING the present month such progress should be made with the general work of the woodlands that towards its end and early in October the forester may be able to give his undivided attention to planting operations. To enable him to do this and to bring the land into a proper state for the reception of the plants, draining, trenching, ditching, and pitting should at once be finished. Pruning should now be brought to a close, and all thinnings removed from the falls. The removal of large evergreens should be finished without delay. Watering, up to the present time, has not been required, and it is to be feared that the cold and sodden state of the land will be unfavourable to late transplanted nursery stock, and, as much of the young wood will not mature upon very wet soils, the plants will be all the more liable to be cut back by spring frosts.

Go carefully through plantations formed last winter, removing dead trees and preparing the ground for filling up. An examination of the plants and the land may to some extent reveal the causes of failure—whether improper planting, too much pruning, a redundancy of moisture, or unfavourable soil. Layers may now be made from coppice stools where the land has been previously loosened and prepared; these should be firmly pegged down and covered with a few inches of soil. Layering may be practised upon the Oak, Ash, Spanish Chestnut, Birch, Alder, Elm, Lime, Plane, Poplar, and Willow. When carefully performed it affords a cheap and expeditious method of filling up thinly stocked coppices; and the connection which is for some time maintained between the layers and the parent stools enables the former to be pushed forward upon rocky soils where newly planted trees would either fail altogether or make very slow progress. Such shoots should be selected as have completed their second year's growth; and if it be not intended to layer again from these, they may be severed from the stools at the end of either the second or the third year, according to the quality of the soil. In good land the shoots from layers will sometimes attain a length of upwards of 4 ft. during the first year.

Lay out and allot coppice falls for the coming season, as the first in the market generally command the highest prices. Small lots by inviting more competition generally command relatively higher prices than large ones. While the weather continues open wash young trees in situations where they are liable to the attacks of hares and rabbits. Towards the end of the month collect the seeds of Birch, Maple, and Sycamore. Those of the Birch, Berberry, and Wild Cherry may be sown at once, and the Maple and Sycamore may be stowed away for spring.

If the ground has not yet been prepared for the smaller evergreens these should now be raised and pitted or planted temporarily in lines upon fairly dry or warm soil ready for after removal. Such plants may be afterwards removed late in the season with greater safety than such as have not been previously lifted.

In the nursery continue to dig between the rows, and clear off weeds by hoeing and raking, removing them to the rot heap, and afterwards treating them with some hot lime. Plant out evergreen hedges—Holly, Yew, Privet, Laurel—and transplant Evergreen Oaks and seedling Hollies.

Where accidents to trees have been occasioned by the late high winds (and these are numerous in consequence of the great weight of foliage and the poverty of the sap), prune off the stumps close to the trunk, and apply a plaster of coal tar or lime and cow manure. All

dead and decaying wood should be removed, and the stump or the wound upon the trunk should be thoroughly dried out before anything is put upon it.

A. J. BURROWS.

Pluckley, Kent.

THE ATHOLE WOODS.*

THE members of the Scottish Arboricultural Society had their second annual excursion on the 7th and 8th inst., when they visited these famous woods. The meeting place on the morning of the 7th was Dunkeld. At the head of the party, his presence warmly welcomed by every one, was Sir Robert Christison, whose memories of these woods, as he himself mentioned, stretch back with perfect distinctness to 1826. After breakfast, the party, under the conductorship of Mr. M'Gregor and Mr. Fairgrieve, started for the woods. In passing Little Dunkeld Bank, Mr. M'Gregor directed attention to several fine specimens of *Pinus Laricio* growing alongside the Scotch Fir, from which the *P. Laricio* stretched away with a markedly superior growth. In no more satisfactory way, indeed, could the members have been afforded an illustration of the advantages that attend the cultivation of this recently-introduced Pine, which recommends itself to foresters by its quick growth and its remarkably clean timber.

Having entered what is called Ladywell Wood, the party was in the midst of the far-famed Athole Forests, which, as is well known, owe their celebrity to the remarkable enterprise of John, the fourth Duke of Athole, whose work is ever an interesting subject for arboriculturists. On succeeding to the estate in 1774, it is stated that he found little more than 1100 acres of ground planted, while before his death, in 1830, the plantations extended over 16,500 acres, there having been planted in this period between 27,000,000 and 28,000,000 trees. In early times Scotch Fir and Oak were mostly used; but successful experiments having been made in the introduction of Larch, of which sixteen plants were obtained in 1738, by the then possessor of the ducal estates, from Mr. Menzies of Culldares, who had brought a quantity of specimens from the Tyrol, the duke was induced in 1786 to cover the rocky heights of Craigeibarns, to the extent of 35 acres, entirely with this species of tree. So satisfactory did this plantation prove, that before his death the duke had put 10,000 acres under Larch, using for this purpose nearly 13,000,000 plants, besides 1,250,000 of other trees. The present duke has planted fully 3000 acres, principally Scotch Fir, mixed with Larch and Spruce. In the course of the stroll through Ladywell plantation, an opportunity was afforded of noting what was apparently abundant confirmation of the belief generally held by foresters, that Larch planted as a second crop on ground on which the same tree had immediately before been raised, does not as a rule succeed.

After passing through the Hermitage coppice a short halt was made, to admire the magnificent view from the Hermitage Bridge. At the north end of the bridge a very fine Cedar of Lebanon was to be observed, and within 30 yards of it is a particularly good specimen of *Abies canadensis*, or Hemlock Spruce, measuring 10 ft. at 4 ft. from the ground, and 80 ft. high. It had originally been double, but one of the limbs has been broken off. A peculiar interest attaches to this tree, on account of the influence it has had in affecting the price of Oak bark, and consequently the price of leather, in this country. The tanning properties of the bark of this tree are so valuable that in America it takes the place of Oak, and is so abundant there that it very sensibly affects the price of leather in this country, the bark of the Hemlock Spruce being sold at something like 15s. per ton, compared with £6 for Oak bark. On entering Craigvinean, "The Craig of the Goats," Mr. M'Gregor called attention to the remarkable way in which Scotch Firs of a few years' growth were dying off. The reason of the decay he could not, he said, explain; but Mr. Sadler discovered, on removing a piece of bark, that between that and the wood a small insect had bored its way through the formative tissue, leaving very distinct traces of its progress. Coming down by the banks of the Tay, attention was called to a fine row of Spanish Chestnut trees, one of which had a beautiful spiral habit of growth. The twist showed no fewer than six distinct spirals, each of them traceable to the top of the tree. The Tay was next crossed, and the party entered the grounds of Dunkeld House. On the way to the American Gardens some splendid old native Scotch Firs, about 150 years of age, were noticed. The bark of all of them was perfectly clean, and had the curious lizard-like scales peculiar to the old indigenous Scotch Fir, which may be accounted for by the fine gravelly soil on which they stand affording good drainage, and keeping the trees in excellent health. One of these trees, taken at random, measured 10 ft. at 5 ft. from the ground. This, however, is not so large

as one met with at the Hermitage, which measured 11 ft. 6 in. at 5 ft. from the ground.

About three o'clock the party arrived at the ancient Cathedral of Dunkeld and after a halt they were photographed in two interesting situations, one of them being on a piece of rising ground under the shade of one of the finest specimens in Scotland of the European Lime (*Tilia grandiflora*), measuring 10 ft. 10 in. in circumference at 5 ft. from the ground. The second photograph was taken in front of the grand old parent Larches. The company afterwards paid a short visit to the New House Park, where amongst the measurements made was a Larch, described as being perhaps the finest specimen in the country. It was 11 ft. 2 in. in circumference, at 5 ft. above the ground, 110 ft. high, and contained 300 cubic ft. of timber; a Spanish Chestnut in the New Park measured 14 ft. 10 in. at 5 ft. above the ground, and 17 ft. 6 in. at 1 ft. above the ground; a Walnut measured 12 ft. 2 in. at 5 ft. from the ground, and about 80 ft. in height; a common Yew at the Cathedral measured 10 ft. 6 in. at 1 ft. above the ground; a variegated Plane (Sycamore) measured 9 ft. at 3 ft. from the ground, and 65 ft. in height; a beautiful specimen of *Magnolia acuminata* 3 ft. 4 in. at 4 ft. from the ground, and 40 ft. high; an Oak on the river bank, 15 ft. 2½ in. at the narrowest part, with a bole about 12 ft. in height, at the top of which are five huge branches, every one as thick as a tree of ordinary size; a Larch on the river bank measured 10 ft. 1 in. at 5 ft. from the ground, 100 ft. in height, and contained 200 cubic ft. of timber. The two parent Larches measured as follows:—14 ft. 6 in. at 5½ ft. from the ground, and 13 ft. 5½ in. at 5 ft. from the ground. Sir Robert Christison pointed out that they had grown 1½ in. since he measured them on June 29, 1878. Many other trees of equally remarkable size were noted.

On the second day the party left Dunkeld for Blair-Athole, and immediately after entering the grounds a very fine belt of native Scotch Fir was passed. Then came a line of Larches which, although not so old as those at Dunkeld, were of considerable size. One taken at random measured 10 ft. at 5 ft. from the ground, and 9 ft. at 7 ft. from the ground, and contained measurable timber to 90 ft. At this place the scenery is of the most magnificent description; the Falls of Fender, half hid by overhanging trees, descending from among the rocks and woods above in a series of cascades, boiling and eddying, falls in a shower of foam into the dark Tilt below. But we are reminded that time and railway trains wait for no man—although we have sometimes to wait upon the latter, particularly on the Highland Railway—and we have to hurry on to see more of the giants of the forest. A short détour was made in order to get a view of Glen Tilt, after which we were conducted through Blairnacher Wood, from which a most charming view was got—Blair Castle being seen in the foreground embosomed in richly-foliaged trees, and Schiehallion, Ben Lawers, and other great eminences towering in the distance all round. At Glaiaceachlaidhe ("Hollow of the Sword") we saw a most thriving plantation, after a crop of Larch, said to have been the finest crop of Larch timber upon the Athole estates. The ground has been replanted with a mixed crop of Pines and hardwood—the Pines, however, having been much destroyed by ground vermin. The hardwood promises to be a really excellent crop of great value, and is making rapid progress. Upon a precipitous bank, sloping to the Banvie, a grand plantation of full-grown timber was observed, consisting of Larch, Scotch Fir, and Spruce averaging from 8 ft. to 10 ft. in circumference, and towering aloft to a height of from 100 to 120 ft. with immense, straight, clean stems; this was altogether the finest timber we saw at Blair Athole.

In the course of this journey one of the most notable objects seen, so far as forestry is concerned, was a magnificent Spruce growing by the side of the Banvie, to the enormous height of 140 ft. measured by a line from the top, and containing no less than 420 cubic ft. of saleable timber.

DRAINING PARKS AND OPEN SPACES.

THE necessity for good drainage has seldom been more apparent than during the past four months, particularly on stiff and retentive soils, and as such work can be executed both cheaply and effectually, it ought by no means to be neglected in parks and open spaces where it is so necessary that the surface should always be in a comparatively dry state, especially those portions to which the public are allowed access. First and foremost, it should be thoroughly understood that it is not the surface water (*i. e.*, the water furnished by rainfall) with which we have specially to contend, but that which lies in the soil, rendering it water-logged, and preventing the free absorption of the rainfall. A reference to the meteorological reports will show that the annual rainfall is really necessary for the support of vegetation, and is readily absorbed or evaporated, except during the winter months, when trees, shrubs, and grass require comparatively little moisture, and evaporation is reduced to a minimum in

* Condensed from a report published in the *Perthshire Constitutional* of August 11.

consequence of the low temperature usually prevalent at that period. In considering, therefore, the best means of getting rid of the subsoil water it will be at once apparent that within certain reasonable limits the drains cannot be either too deep or too large to effectually accomplish the desired purpose. I think it is a mistake to apply to different soils various depths of drainage as is generally supposed to be necessary and often recommended; one general depth should be adopted which would answer the purpose of thoroughly draining parks and open spaces, and maintaining the vegetation therein in a healthy condition.

Having by means of surveys ascertained the position of the ground, the various levels, and fixed upon the most convenient point for the outfall (which for obvious reasons should be the lowest), the direction of the main drain or drains, as may be necessary, must be decided upon; in doing so the low-lying portions of the ground or valleys should be chosen, and, if possible, straight lines taken to the outfall. The capacity of the mains will depend upon their length, the area of the ground, and the state of the soil, whether wet or very swampy. As, however, it is always best to err on the safe side, I would recommend for large parks or open spaces and very wet soils, 9-in. mains; and for smaller and less swampy areas 6-in. mains.

With regard to the depth at which drains should be placed beneath the surface I am of opinion that from 5-ft. to 6-ft. drains are the most effective for the areas under consideration. A moment's examination of the annexed diagram will render the difference between deep and shallow drainage intelligible. If we assume a surface area 20 ft. in width, and drains placed at a depth of 3 ft. and 6 ft. respectively as shown, it will at once be evident that the angle of percolation is more acute, and therefore more rapid and effectual when the drain is placed at the greater depth, and at the same time

Deep and shallow drainage.

the subsoil below the line AA is drained, which would not be the case were the drain placed at B; this alone will prove the great advantage gained by placing the drain at C. Again assuming the angle of percolation as shown to the drain at B to be applied to both cases, further evidence will be furnished in favour of the greater depth, owing to the larger amount of work done—that is the drain at C takes the water from a greater depth and drains a larger superficial area; therefore, whilst the cost would be about equal in both instances the gain in regard to effect would be greatly on the side of the deeper drain. There need be no anxiety with respect to the water finding its way to the drains, even in the stiffest and most retentive clays, as the roots of plants, worms, the stratification of the soil, and the specific gravity of the water itself, all combine to ensure success. Sometimes assistance is given by partly filling up the trench after the pipe is laid with stones, chalk, or rubble of any kind, faggot wood or Furze and similar material. This, however, is simply making the drain larger, and the same effect would be the result if we were to lay two or three rows of pipes instead of one; but there is really no special advantage to be derived from such a practice. In filling up the trench after the drains are laid, if ordinary care be taken to throw in the roughest of the soil first, it will answer all the purposes of the above-mentioned materials.

The fall necessary for drains will much depend upon the natural surface of the soil, but, if possible, it should not be less than 1 ft. in 700 ft. or 800 ft. The trenches must be filled in without ramming, leaving the soil above the surface and allowing it to settle, filling up again if necessary in the course of a month or so, and ultimately rolling the surface if of Grass. Lateral drains may consist of 2-in., 3-in., or 4 in. pipes in proportion as the subsoil is very wet or otherwise, and they should be made in exactly the same manner, both as regards depth and fall, as is recommended for the mains. These drains should be laid obliquely to the fall of the ground, never in direct lines with it. By so doing they act more perfectly as catches for

the water by intercepting its natural flow, and consequently carry it more rapidly to the mains. The distance between the lines of lateral or side drains will depend upon the nature of the soil in respect to moisture, and may vary from 20 ft. to 60 ft.

In cutting the trenches care should be taken that the bottom is no larger than is necessary to admit the drain pipes, which may be very neatly done by the aid of tools usually employed in such work. This prevents the possibility of the line of pipes becoming deranged in filling up the trench or as the soil settles down, which would otherwise obstruct the flow of water and seriously interfere with the success of the work. The junction of lateral with main drains should be at as acute an angle as possible; the object of this will be evident, as offering the least possible resistance to the flow in the mains. Pipes of short length are preferable to long ones, giving, as they do, greater facilities for the percolation of the water. It will generally be some few months before the drains are in full working order, especially in stiff soils, in consequence of the water forming its channels to the drains; once, however, they begin to "draw," the success of the work will be evident. Drainage properly carried out during the months of September and October should be in full working order by the following March.

Without giving very definite data with regard to the durability of pipes for drainage purposes, I may say it is well to choose those which are thoroughly burnt, discarding all of a soft texture as liable to rapid decay when exposed to long-continued moisture, which must necessarily be the case with drain pipes. Some time since I had an opportunity of examining some pipes which were used many years ago in draining a stiff clay, and which appeared to be none the worse for the wear. The foregoing refers only to what is termed under-draining of land and in no way applies to roads and walks, or to the more superficial drainage of cricket, croquet, and such-like grounds. It will also be found necessary on open spaces to pipe and fill up useless and unsightly ditches, which in many cases may act as main drains if placed sufficiently deep, taking particular care to protect the pipes from the roots of large trees which may be growing near their course. —C. DENNIS.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Rosa lucida.—This is a handsome single Rose, which may be worth the attention of the few persons who take an interest in such subjects. We noticed with this at Bitton a handsome and vigorous double Rose, which Mr. Baker calls the true *Rosa sinica*, but which has probably been sent out under some florist's name, as it has good qualities, viz., hardiness, good foliage (resembling somewhat the Macartney Rose in this respect), a tea-scent, and abundance of flowers and buds in succession, at this season.—V.

The Annual Timber Sale on the Longleat Estate, Wilts, took place at Horningsham, on the 26th August. The timber was mostly second-class, and of small dimensions. The prices realised were upon the whole slightly lower than those of last year's sale. The following are the average prices:—Oak, 11 ft. average, 1s. 2½d. per ft.; Ash, 8 ft. average, 2s. per ft.; Beech, 36 ft. average, 10d. per ft.; Scotch Fir, 23 ft. average, 7d. per ft.; Larch Poles, 3½ ft. average, 11d. per ft., or 3s. 4d. per pole; Oak Saplings, 3s. 2d. each; Faggots, 21s. per hundred (6 score).—G. BERRY.

Large Spanish Chestnut.—At Underbank Hall, in Yorkshire, there is a Spanish Chestnut which measures 17 ft. 2 in. in circumference at 1 yard from the ground. It is well grown and perfectly healthy, and apparently has not yet finished growing. Surely it is unusual for this tree to attain such dimensions in so high a latitude.—Field.

Ceanothus azureus.—On a south aspect, this is at present in excellent condition, covered with beautiful azure blue flowers. Last winter's severe weather killed all the young wood, and we had to cut it in close to the old wood. But the plant appears benefited by the hard pruning to which it has been subjected, and has produced an unusual display of flower spikes.—G. L.

Colutea Pococki.—This distinct-looking Bladder Senna is a handsome shrub in flower at this season; the flowers are of a brownish-red colour, and produced very abundantly.—V.

Billiardiera longiflora.—This plant has proved very hardy at Bitton, and now bears curious blue fruit against a wall there. It seems a fragile little shrub.—R.

Calycanthus occidentalis.—This shrub is now very large and full of flower in the garden at Bitton. It is so striking and distinct that it deserves to be grown well among the choicer kinds of shrubs, and in a position where it may not be injured through over-crowding or shading.—V.

The Rosemary-leaved Willow.—*Salix rosmarinifolia* is a very graceful Willow, and quite distinct in appearance from any other. It well deserves culture as an ornamental shrub.—V.

Rubus biflorus.—This Bramble fruits freely in the garden at Bitton, and the fruits have a pleasantly acid flavour. They are not very large, and of an orange colour.

Christ's Thorn.—This shrub, seldom seen out of botanic gardens, is not without beauty at this season, when its branchlets are freely studded with small yellow blossoms. At Bitton several specimens of it in flower are very interesting just now.
